material also permits of its being readily cut on the site of the works. This adaptability of the casing is, of course, of great importance, especially in localities when the ground is already occupied by gas, water, and other pipes. The method ensures a separate continuous and smooth "way" for each cable. The ducts in adjoining lengths of casing, in the process of jointing,

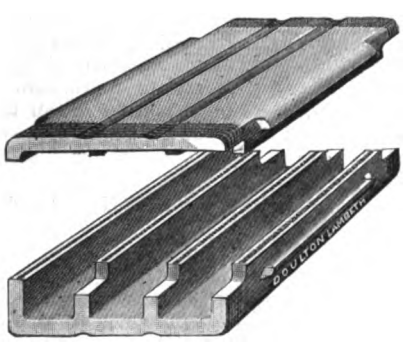

FIG. 3.

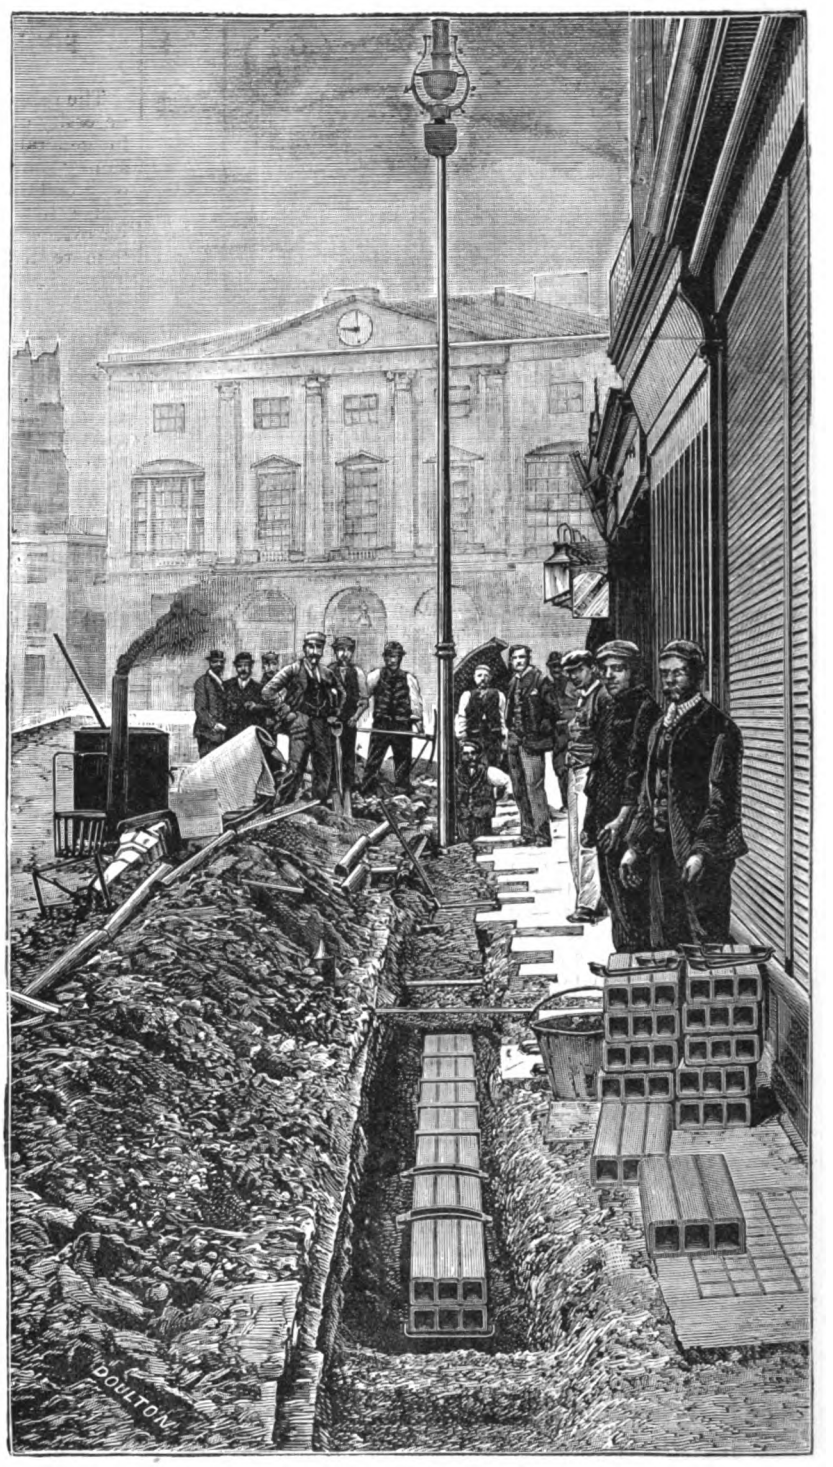

FIG. 4.

are accurately centred one with the other. The operation of drawing cables in or out is therefore performed with the minimum of labour and risk. Glazed stoneware, as a material for use in underground electrical work, possesses two important qualities—viz., it is a non-conductor of electricity, and it is incorrodible and imperishable. Further, it has the advantage of being cheaper than metal or other materials in use. The Doulton casing gives every facility for making house connections. For this purpose stoneware boxes may be introduced into the line at the time of laying the conduit, or there is no difficulty at any subsequent time in cutting out a portion of

PLUME SHADES.

We illustrate herewith some incandescent lamp shades which are being brought out by Messrs. Charles Ingle and Co., 157, High Holborn, the designs being mainly by Miss Beatrice Devonport. The material employed is swan's feathers, which lend themselves to artistic treatment, and various tints are employed, such as cream white, dark green, light green, salmon pink, rose pink, terra-cotta, amber, blue, and lilac. Provision

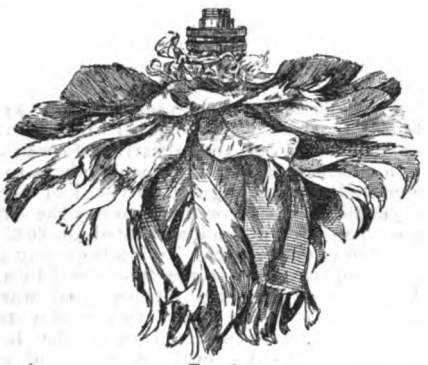

FIG. 1.

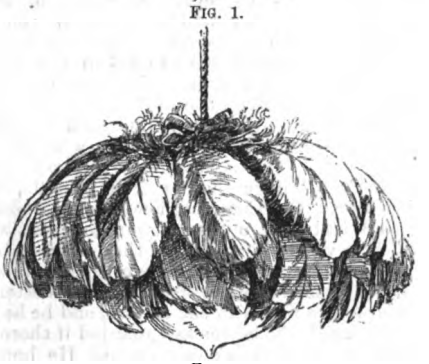

FIG. 2.

FIG. 3.

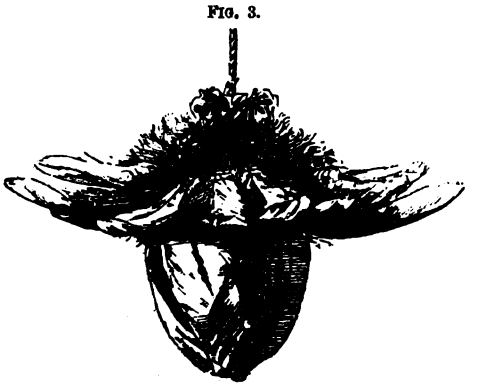

FIG. 4.

is made for an air space between the incandescent lamp and the shade. The designs which we illustrate are entitled: Fig. 1, rose; Fig. 2, water-lily; Fig. 3, tulip; and Fig. 4, fuchsia.

Bedford.—A requisition signed by three members of the Town Council has been handed to the town clerk, calling for a special meeting of the Town Council for the purpose of adopting or rejecting a resolution that application be made for a provisional order to supply electricity for public and private purposes within the borough. In compliance with the requisition, and with the sanction of the Mayor, the town clerk has already issued summonses for a special meeting to be held on Monday, November 19, in the Council-chamber.

NEWCASTLE-ON-TYNE TRAMWAYS.

Messrs. Siemens and Co. have made the following reply to the borough engineer's report on the above tramways:

On June 13th, 1894, the city engineer presented a report to the Town Improvement Committee of Newcastle-on-Tyne on the best system of tramways for that town. The report deals with three systems: (*a*) horse-traction system; (*b*) conduit electric system; (*c*) cable system; and advocates strongly the adoption of the last-named.

A considerable portion of the report is taken up with adverse criticisms of the conduit electric systems which are actually in operation at Blackpool, Lancashire, and at Buda-Pesth, in Hungary. A perusal of this portion of the report cannot fail to prejudice any body against the conduit electric system; and it is desirable to reply to some of the objections made, and to correct the more striking inaccuracies which have crept into the report. In the first place no comparison is possible between the lines at Blackpool and at Pesth, as the systems adopted are essentially different; consequently the following remarks are confined to the Buda-Pesth system.

The objections raised in the report fall under the following headings: (1) width and gradients of streets; (2) speed for the service; (3) width of the slot; (4) form and construction of conduit; (5) interruption of service from climatic causes; (6) working expenses; and it may be well to take them in order.

The report states that while the conduit electric system is very suitable for the very wide and flat streets of Pesth, it would not answer in the narrow and hilly streets of Newcastle. Though it is quite true that Pesth possesses some magnificent streets, not unfrequently 150ft. to 200ft. wide, in which there is ample room for the ordinary traffic to run alongside the tramway, yet this is not the whole truth; for the electric tramway passes through many streets which at least approximate to the narrowness of those in Newcastle, without any disturbance to the ordinary traffic. Thus the conduit electric tramway runs: through Szechenyi-street, which is 48¾ft. wide; through Woll-street, which is 47½ft. wide; through Calman-street, which is 47¾ft. wide; and through Baross-street, which is 39ft. wide. In these streets there is a single track, but a double track runs through König-street, the width of which is 47¾ft. Nor can it be said that Pesth is flat; for on the course of the tramway there are inclines as steep as 1 in 50 for some length. In this connection reference may be made to the statements in the report that the electric system of tramways has not yet been introduced into the neighbouring town of Buda, on the opposite side of the Danube, because it is hilly, and that the authorities are enquiring into the possibility of introducing the cable system. The real cause why tramways have not been introduced in Buda is that while Pesth is a busy commercial town, its sister Buda had an amount of traffic which was not sufficient to warrant the introduction of the tramway. Plans for a conduit electric system have been got out and laid before the authorities of Buda, whose decision on them is now being waited for; but they have never even contemplated using cable traction.

The statement that the average speed of the electric cars in Pesth is 12 miles an hour, a speed inadmissible in Newcastle, needs correction. The maximum speeds at which the cars may travel, and beyond which the driver dare not go, are as follows: in the suburbs, 11¼ miles an hour; in the wider streets, 9¼ miles an hour; in the narrow streets, 6¼ miles an hour; at street crossings, 3¾ miles an hour; so that the average speed is about that of Newcastle—viz., eight miles an hour.

It is true that the width of the slot at Pesth is 1¼in., but it must be borne in mind that the slot was not made 1¼in. wide to accommodate the electric collector; but the electric collector was arranged to work in the slot which already existed for the wheel flanges, and that it was owing to the wheel flanges having to run in the slot that the latter was made so wide. There was no need to provide a slot 1¼in. wide for the electric collector, and there is no difficulty whatever in contracting the slot to a width of ¼in., equal to that used for a cable grip, at a depth of about 1in. below the surface. Indeed, the working drawings of a conduit electric tramway with a contracted slot of this nature have been got out, and would be followed in the construction of any new line. Even though a bicycle wheel should drop through the slot, it could not short-circuit the conductors, since these are not placed vertically below, but to either side, and consequently the wheel would not touch them.

The construction of the track is stigmatised as "flimsy," and yet costing £1,000 per mile more than the cable traction system. The report gives the cost of construction of the Pesth tramway as £12,000 per mile, which sum has apparently been deduced from the total capital of the company. The actual cost of construction was one-third of this—viz., £4,000 per mile—as was stated by Dr. John Hopkinson in his evidence before the Hybrid Committee in 1893 on the Protective Clauses to be introduced into Electric Tramway Bills. A few figures will serve to refute the charge of flimsiness: rails, fish-plates, etc., weigh 180lb. per yard; supports and fittings, 150lb. per yard; conductors, 30lb. per yard; or a total weight of iron and steel of 360lb. per yard. Such a construction would satisfy the mind of any engineer as to its power of supporting heavy loads. The Hungarian Ministry of Commerce prescribes that the calculations for such constructions are to be based on the assumption that they will have to bear two-axled wagons of 24 tons weight. It is quite incorrect to say that the rails of the Pesth tramway rest on "loose brickwork"; on the contrary, the rails rest on and are securely bolted to cast-iron frames of square shape, which are embedded in the concrete

Digitized by Google

conduit at distances apart of about 4ft. The brickwork referred to in the report is simply used to make up the level above the concrete conduit, and does not support the rails at all; and it is not "loose," but properly bonded brickwork laid in Portland cement. In case of its being necessary to gain access to the conductors, a rail has not to be taken up, but only a few granite setts.

It is possible that snow may have stopped the electric tramway at Blackpool for days together, but nothing of the kind has ever been the case at Pesth, where the service on the electric tramway has never yet been interrupted for a whole day. As a rule, the electric tramway was stopped no longer than the horse tramways to allow of the snow being cleared away. To give some idea of the cost of clearing the snow, it may be mentioned that in the winter of 1893, when the snow was very heavy, it only amounted to 1·2 per cent. of the receipts. The suggestion in the report that the traffic might be interrupted by a piece of damp paper being blown into the slot and coming into contact with the conductors, is of course utterly groundless, and can only have originated in some total misconception of the nature of the electric currents used. Indeed, "short-circuiting" seems to be held up rather as a bogey in the report, possibly because it was not quite understood. The moister English climate need not be feared in connection with a conduit electric system, since the conduit can always be efficiently drained, and the conductors are well placed to the sides out of the way of moisture.

The reasons which are given as accounting for an increased cost of working in England are fallacious. Thus it has been shown here that the average speed in Pesth is not more than in Newcastle, but the same, and therefore the car mileage is not increased. It is true that labour is cheaper in Hungary than in England, but labour is a smaller proportion of the working charges than coal, oil, and all stores, and all these are certainly far cheaper in Newcastle than in Hungary. The difficulty of surmounting inclines can be especially attacked with electric trams, for each axle of the car can be made to drive, and consequently the whole weight of the car can be utilised for adhesion. At Buda-Pesth an experimental incline of 1 in 10 was tried, and it was found that an ordinary car of the electric tramline with a single 16-h.p. motor driving on to both axles could surmount it easily at a speed of 5½ miles an hour.

The above remarks are based on information received direct from the Buda-Pesth Tramway Company, to whom a copy of the engineer's report had been sent.

COMPANIES' MEETINGS.

WESTMINSTER ELECTRIC SUPPLY CORPORATION, LIMITED.

An extraordinary general meeting of this Company was held on Wednesday at Eccleston-place, Belgravia, to consider a resolution for increasing the capital by £100,000. Lord Suffield occupied the chair.

The **Chairman** explained that the proposed increase was rendered necessary by the very large growth of the business. It was not the intention of the directors to apply the extra capital asked for in erecting new buildings or in extending the area of supply, but it would be expended in the purchase of plant, meters, cables, etc., to meet the demand of the present district. On December 31, 1893, the lamps on circuit numbered 131,565 of 8 c.p.; now there were 158,000 lamps and about 9,000 more were waiting to be connected, while applications were still coming in at the same rate. It was proposed to offer the new shares to existing shareholders, but he ought to point out that it was not intended to issue the whole or any large part of the additional capital at once. After the resolution had been passed, the Board would consider the amount it was at present advisable to issue, and then communicate with the shareholders as to the terms, and invite them to subscribe to the first instalment. He then moved a resolution for increasing the capital from £300,000 to £400,000.

Mr. E. Boulnois, M.P., seconded the resolution.

In reply to a **Shareholder**, who enquired if the Board could not see their way to issue the shares at par, the **Chairman** said it was deemed prudent to charge a small premium with which to commence the nucleus of a reserve fund.

The resolution was agreed to.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.

The general meeting of the shareholders of the Brazilian Submarine Telegraph Company was held at Winchester House on Wednesday, Sir J. Pender being in the chair.

The **Chairman**, in moving the adoption of the report, stated that the receipts of the half-year ended June were £94,679, those of the previous half-year having been £96,262, showing a decrease of £1,583. The receipts from messages showed a decrease of £1,393, and from miscellaneous receipts, including interest, rents, and transfer fees, a decrease of £190. The decrease in the amount of interest was due to the low rates allowed by the Bank of England on deposits. Having regard to the further fall in the value of the Brazilian currency, the decrease in the receipts from messages would have been much greater but for the fact that the Company's lines had carried some 40,000 more words in the previous half-year. This showed a satisfactory growth of traffic in South America. News telegrams had increased, and the Company was desirous of affording facilities for fostering that traffic. As compared with the corresponding half-year of 1893, the income from messages showed a decrease of £12,181, but this decrease was fully accounted for by the difference in exchange. In the half-year of 1893 the average rate per milreis was 12½d., whereas in the half-year now under review the rate was only 9½d. During the current half-year the rate had reached 12⅜d., and was now 11⅜d.—an improvement due to the more settled state of affairs in Brazil and to a splendid coffee crop. The working expenses during the half-year amounted to £20,269, those of the previous half-year having been £24,284. The decrease of £4,015 was due to the fact that their cables had been, fortunately, free from interruption. The working expenses at the stations were £13,026, as compared with £13,064 during the previous half-year. The interim dividend of 1½ per cent. paid in June absorbed £19,500, £15,000 had been transferred to the reserve fund, and the directors now recommended a final dividend of 3s. per share, making, with the interim dividends, a total dividend of 6 per cent. for the year, and also the payment of a bonus of 1s. 2d. per share, which together will amount to £26,000, leaving a balance of £1,501 to be carried forward. That, he thought, was a most satisfactory statement to have to make. All interests connected with foreign countries had been sufferers, more or less, yet that company was able to pay the same dividend in bad times. The reserve fund amounted to £692,269, contributions during the past 18 months having been only £42,000, but with the interest on investments the fund stood in a satisfactory position. A large and growing reserve fund was absolutely necessary, seeing that there were two cables to maintain, and, sooner or later, to renew. During the half-year the directors had caused to be made 90 miles of cable, at a cost of £16,000. Since they had undertaken the working of the Pacific and European Telegraph Company they had more than doubled the traffic. They had also £40,613 in the European and Azores Telegraph Company, and though he was not in a position to make any definite remarks on the subject, the Eastern Company had secured a concession from Germany which would give their Company not only special advantages but a subsidy from the German Government. The Brazilian Government having held that the Company's privileges had expired in 1892, had imposed a tax on their traffic. The Company held that the concession had not expired, and had sent out an agent to assist at a friendly arrangement. The visit was made at a time of civil disturbances, and their agent was sent out in the hope of coming to some understanding with the Brazilian Government. The Western Brazilian Company was equally affected in the matter, and he held that their common interests might be better safeguarded if there could be a closer alliance between these two companies. He hoped that the time was not far distant when this question would be fairly considered by both bodies of shareholders.

Mr. Brodrick, M.P., seconded the motion for the adoption of the report and the declaration of a dividend.

The motion having been agreed to, Sir J. Pender and Mr. Brodrick were re-elected directors, and the proceedings closed with a vote of thanks to the chairman.

VENEZUELA TELEPHONE COMPANY, LIMITED.

The ordinary general meeting of the Venezuela Telephone and Electrical Appliances Company, Limited, was held on Tuesday at the offices, 37, Lombard-street, E.C.

Sir Douglas Fox presided, and stated that the report the directors presented was unmistakably the most satisfactory one that had been submitted since the initiation of the Company. The profit for the year amounted to £7,413, as against £4,143 last year, and the sum actually earned, leaving out of the question balances, was £2,753, which showed that they were now established on a firm basis, and were able to make a fair return not only to the debenture-holders but to the shareholders. Since the present manager (Mr. Wallis) was appointed there had been a considerable reduction in the operating expenses on the other side of the water, while the business had increased from £18,444 last year to £21,284 this year. He believed that, owing to the efforts Mr. Wallis was making, they might fairly hope for a further reduction in the operating expenses. At present they stood at 56 per cent., as against 60 per cent. last year. Their capital, which amounted to £152,900, exactly represented the sum which had been expended—that was to say, cost of the property, stores, and material at Caracas. He attributed the present satisfactory financial position of the Company to the businesslike arrangements made by Mr. Philipps when he visited the property recently. He concluded by moving the adoption of the report and accounts.

Mr. J. W. Philipps seconded the motion.

Mr. E. A. Wallis (the manager) stated that during the year the subscribers had increased in Caracas by 195, in La Guaira by seven, in Valencia by 21, and in Puerto Cabello by 16, making a total increase of 239 subscribers over the year 1893.

The motion was agreed to.

After the re-election of the retiring director and auditors, a vote of thanks was given to the chairman and Board.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

London, W.C.—To-day is the last day for the delivery of tenders for the electrical plant wanted by Mr. John Annan, manager for Mr. Samuel Wheeler, "Official Receiver in Companies Liquidation," acting as liquidator of J. W. Hobbs and Co., Limited, for the hotel in course of completion on the Salisbury Estate, Victoria-embankment.

Digitized by Google

Hapton (Lancs.).—Tenders are invited for lighting with electric light the village of Hapton and so much of the township of Hapton as the lighting inspectors may think necessary. Full particulars may be had of the work required to be done by applying to Mr. Henry Cunliffe, chairman of the Lighting Inspectors, Post Office, Hapton, to whom tenders are to be delivered by 27th inst.

Sunderland.—The Corporation require tenders for wiring the Town Hall, including the supply and fixing of all cables, casings, switch and fuse boards, lamps, etc. Copy of specification, etc., may be obtained at the office of the borough electrical engineer on the deposit of £1. 1s. Further particulars are given in our advertisement columns. Tenders must be delivered at the office of Mr. Fras. M. Bowey, town clerk, not later than November 8.

London, E.C.—Tenders will be received until noon on Wednesday, 31st inst. (*a*) for supply of red fir telegraph poles, to be delivered in London, King's Lynn, or Sutton Bridge, and at Northumberland Dock (River Tyne), West Hartlepool, Hull, or Grimsby; and (*b*) for creosoting the poles with 10lb. or 12lb. of creosote to the cubic foot as may be directed. The poles to be felled between November 1, 1894, and February 28, 1895 and to be delivered during the following summer at the port at which the creosoting is to be performed. Butt sections from not less than three poles, to show the quality of timber offered, must precede or accompany the tender of any person who has not already supplied the Postmaster-General with poles. The Postmaster General does not bind himself to accept the lowest or any tender. Forms of tender, containing all particulars, may be obtained on application to Chas. E. Stuart, controller of stores, Telegraph-street, E.C.

RESULTS OF TENDERS.

Tonbridge.—The Board of Guardians have accepted the tender of Mr. E. Powell, of Grove Hill-road, Tunbridge Wells, to erect and maintain a complete telephonic system in the house for seven years at £12 per year.

Cardiff.—The Corporation have received the following tenders for wiring the Town Hall and market buildings for electric lighting purposes, including the supply and fixing of all cables, casings, switch and distributing boards, etc., but not lamps and fittings:

	Town Hall.	Market.
Maunsell Mercier and Co.	£264 0 0	£198 0 0
Fergus and Co. (accepted)	338 0 0	185 0 0
Clay Bros. and Co.	318 0 0	245 0 0
Fowler, Lancaster, and Co.	493 15 0	232 10 0
F. W. Ball and Co.	553 5 7	507 18 9
W. and T. Robinson, Limited	636 10 0	480 17 0
J. B. Saunders and Co.	678 0 0	483 0 0
S. Walker and Co.	705 0 0	610 0 0
Knapman, Hodder, and Co.	994 18 6	740 7 6

BUSINESS NOTES.

Derby.—The Assembly Rooms have been lighted electrically.

Colchester.—The new public library, which was opened yesterday, is lighted electrically.

Western and Brazilian Telegraph Company.—For the past week the receipts were £3,215.

York.—The electric light has been installed in the buildings of the York Steam Laundry Company.

Bristol.—The Corporation are being asked to extend the electric light mains to the Croft and Arley Chapel.

Cheltenham.—Messrs. Weyman, Hitchcock, and Co.'s new engineering works are to be lighted electrically.

Coventry.—The Town Council have decided upon 6d. per Board of Trade unit as the charge for the electric light.

Cadley Hill.—Messrs. Hewes and Geary have lighted the colliery of Messrs. Hall and Boardman at Cadley Hill by electricity.

London Electric Supply Corporation, Limited.—The offices of this Company have been removed to 25A, Cockspur-street, S.W.

Leeds.—The Theatre Royal is to be altered, and among the improvements to be introduced is the installation of the electric light.

Nottingham.—There have been 54 applications made for current, and at present 35 consumers are connected with the mains.

Worcester.—The Union Club is to be lighted electrically, the work being carried out by the New British Electrical Contractors, Limited.

Chiswick.—Good progress is being made by Messrs. Bourne and Grant in preparing the ground for the engine-house for the central electric light station.

Indo-European Telegraph Company.—The directors have declared a half-yearly interim dividend at the rate of 5 per cent. per annum, payable on November 1.

London, W.—Messrs. Rashleigh Phipps and Co., of Oxford-street, are carrying out an electric light installation on the premises of Mr. Anderson Critchett, Harley-street, W.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 21st inst. amounted to £888, as compared with £611 in the correspondingweek of last year.

Brechin.—At a special meeting of the Police Commissioners it was agreed to accept the offer of the House-to-House Electric Light Supply Company to provide electric light for the burgh.

Edinburgh.—Messrs. Adair and Co., South Bridge, have introduced into their premises electric lighting by arc lamps. Their premises are the first in the city to adopt this method of illumination throughout.

Burton.—Messrs Hewes and Geary have fitted up the office of the *Burton Chronicle* with the electric light. The same firm have obtained a contract for an installation at the potteries of Messrs. Cash, Massey, and Co., Limited.

Hall Electrical Company, Limited.—This Company has been registered, with a capital of £4,000, to acquire and carry on the business of an electrical engineer as hitherto carried on, under the style of A. Hall and Co., at Liverpool.

Bournemouth.—The Roads Committee of the Town Council recommended that plans be passed for a transformer pit in Beckford-road, and an extension of the main in Sea-road, Boscombe. The report was adopted.

Whitechapel.—The District Board have given permission to the City of London Electric Lighting Company to lay a main from the south-western corner of the Minories to the Dock House for the purpose of supplying electricity to one of the company's warehouses in St. Katharine's Docks.

North Staffordshire.—The Duke of Sutherland has just commenced some important improvements on his Trentham estate in North Staffordshire. The hall itself is to be lighted by electricity, power being obtained from the River Trent, which will be specially deepened for the purpose.

Eastern Telegraph Company, Limited. — This Company announces the payment by warrants on November 1 of interest for the half-year ended October 31 on its 4 per cent. mortgage debenture stock. The transfer books will be closed from October 27 to November 1, both days inclusive.

Charles Joyner and Co., Limited.—This Company has been registered, with a capital of £35,000, to acquire as a going concern the business of manufacturers of fittings connected with lighting with oil, gas, or electric light carried on by Charles Joyner and Co., of Icneild-square, Birmingham.

Beverley.— Mr. J. Scarr, shipbuilder, of Grovehill, has been the first to adopt the electric light in Beverley. The whole of his works have been fitted up by Mr. S. P. Wood, of Hull, whose electrical engineer, Mr. Ernest M. Parsons, has carried out the details in a very satisfactory manner.

St. Saviour's.—The Board of Works for the St. Saviour's District have completed the construction of a large underground lavatory, etc., at the junction of the Borough High-street and Southwark-street, near the commencement of the approach to London Bridge. It is lighted by electricity.

City and South London Railway.—The receipts of the Company for the week ended October 21 were £932, against £810 for the corresponding week of 1893, or an increase of £122. The total receipts for the current period of the present half-year amount to £13,863, as against £12,956 in the corresponding period of 1893, an increase of £907.

Agency.—Mr. L. Barrière, 22, Rue St. Sabin, Paris, informs us that he has appointed as his sole agent for Great Britain and the Colonies Mr. G. Straus, 130, Queen Victoria-street, London, E.C. He also calls attention to his works fitted with all the latest labour-saving machinery for producing metal screws, terminals, and all kinds of metal turning.

London, E.C.—Messrs. Strode and Co., of St. Paul's-churchyard, are installing the electric light at 3, Fenchurch-avenue. At Tuesday's meeting of the City Commission of Sewers, on the motion of Mr. Gordon, it was referred to the Streets Committee to consider the advisability of including Finsbury-circus among the main streets for electric lighting purposes.

Change of Firm.—The electrical light business of Mr. W. E. Hayne, 29, Western road, Brighton, has lately been acquired by Mr. Thos. King, of Maidstone, and will be carried on under the management of Mr. Chas. Rawlings. Owing to ill-health Mr. W. E. Hayne has been compelled to retire from practical work, but will act as consulting engineer at Ebor House, Bexhill-on-Sea.

Blackpool.—The report of the Blackpool Winter Gardens and Pavilion Company, Limited, for the year ending September 30 states that the installation of the electric light throughout the buildings has been carried out at the cost of £3,307, which has been paid out of the reserve, leaving a balance at the credit of that fund of £193. Complaints have been made as to a smoke nuisance at the electricity works.

Monmouth.—The Council in committee have reduced the number of proposed sites for the works required for the combined drainage and electric lighting scheme to two—viz., the Osbaston farm and Brooksholme. Negotiations with a view to a final decision are now to be opened up. The engineers stated that they would be able to complete the works in about a year from the time of commencement, which would be undertaken immediately the sanction of the Local Government Board had been obtained.

Monte Video Telephone Company.—The accounts for the year ended July 31 last show a net profit of £6,902. 15s. 11d. After making provision for all working expenses in Monte Video and London, depreciation of stock of materials in Monte Video, and writing off the final amount of preliminary expenses, there remains an available balance, including the amount of £775. 2s. 9d. brought forward from last year, of £7,677. 18s. 8d. The directors recommend the payment of a dividend of 4 per cent. on the preference share capital, absorbing £5,600, which, after placing £1,000 to reserve account and £500 to reserve for bad and doubtful debts, leaves the sum of £577. 18s. 8d. to be carried forward to next year.

Digitized by Google

British Electric Light Company.—Mr. Justice Stirling, on Wednesday, heard a motion asking, on behalf of the holders of a series of debentures, for the appointment of a receiver and manager of the British Electric Light Company, Limited. Counsel stated that under the terms of the debentures, if the principal money was not paid on July 31, 1894, the whole of the Company's undertaking and property should become specifically fixed and charged therefor, and that principal and interest should forthwith become payable. Payment of the principal had been demanded and had not been made, and the interest had been in arrear for a year. The Company did not appear, and his Lordship said there would be the usual order.

Bath.—The Surveying Committee of the Town Council have received a letter from the Rev. G. C. Clarke, of St. John's Priory, with reference to the lighting of South-parade. It appeared that the sub-committee had proposed to move the electric light standard from one position to another, but to this the residents objected. Mr. Clarke suggested that another gas lamp should be erected midway between the two electric lights by the side of the asphalte walk under the trees. Alderman Bright believed it was proposed by the sub-committee to cut down some of the trees. It would be an act of vandalism to remove one of them. He moved that the extra lamp asked for be erected. Alderman Sturges seconded, and the proposition was carried.

Bacup.—The report of the Health and Baths Committee of the Town Council stated that the chairman submitted a communication from Messrs. Richardson and Herbert, electrical engineers, of Manchester, with reference to lighting the baths by electricity, using the steam from the present boilers for the engine. They estimated (roughly) the lights required as two arc lamps of 2,000 c.p. each for the second-class bath, two of 3,000 c.p. each for the first-class bath, and 29 incandescents, equivalent to 30 16-c.p. lights, for the remainder of the building, and the cost of the installation, including steam-engine and dynamo, but exclusive of foundations, at about £180. It was resolved that the matter be left over for the next meeting of this committee to deal with.

St. Pancras.—The Electricity Committee of the Vestry have reported that the chimney shaft had been completed, and that the work connected with the erection of the central electric station buildings and destructor buildings on the King's-road site was being steadily proceeded with. It was deemed desirable to acquire the freehold of the site, and for this purpose, as well as to meet the contracts let in connection with the destructor buildings and appliances, the central electric station buildings, electrical machinery, and mains, a sum of £65,000 was required. Hence the committee recommended that application be made to the London County Council for a loan of £65,000, repayable by equal instalments of principal and interest combined in 42 years. The report of the committee was adopted.

Paddington.—The Infirmary Committee of the Paddington Board of Guardians recommended that steps be taken to light the wards of the infirmary with the electric light. The Rev. C. Dent moved the adoption of the recommendation. Dr. Felce seconded it. Mr. Sherrard moved that the administrative block of the infirmary be included in the recommendation. Colonel Blair seconded this. General Whish, Mr. Empson, and Mr. Jephson spoke in favour of the proposed addition. Messrs. Dent and Swift, Mrs. Charles, and the Chairman argued in favour of the recommendation as sent up by the Infirmary Committee. It was in the end decided by eight votes to six to adopt Mr. Sherrard's proposal. The recommendation as amended was then carried. St. Saviour's Church has been lighted electrically.

Electric Fittings.—Messrs. B. Verity and Sons inform us that they are exceedingly busy in their fittings and electrical accessories departments, being obliged to extend their works at Aston and put down additional machinery in order to cope with the pressure of orders. Among the principal contracts in hand for fittings are the following: Southport Municipal Buildings, assembly hall, etc.; Worcester Guildhall and Municipal Buildings; Burton Town Hall and Municipal Buildings, Church Institute, etc.; and Cardiff Town Hall and Municipal Buildings, St. Mary's Markets, etc. They have also some large trade orders for switches, lampholders, general sundries, etc., the switch factory especially having to work overtime in order to keep pace with the heavy demand, the output of their new key sockets alone having been doubled within the last month.

New Mains in London.—Permission has been granted by the London County Council to the Westminster Electric Supply Corporation to lay a service main across North-row, North Audley-street; to the London Electric Supply Corporation to lay distributing mains in Heddon-street and court, Regent-street; to the Vestry of St. Pancras to lay mains in Gloucester-road and across Regent's Park-road; to the House-to-House Electric Light Supply Company to lay mains in Scarsdale-villas from Marloes-road to Allen-street; to the Notting Hill Electric Lighting Company to lay mains across Chepstow-villas and in a part of Holland Park; to the County of London and Brush Provincial Electric Lighting Company to lay mains across Rosebery-avenue at six places, and on both sides of that thoroughfare from Farringdon-street to St. John-street-road; and to the Kensington and Knightsbridge Electric Lighting Company to lay mains in Bute-street, Pelham-street, Harrington-road, and Glendower-place.

Lancaster.—A letter has been read at a meeting of the Rural Sanitary Authority from Mr. Sydney Moore, secretary of the Windermere District Electric Supply Company, asking for the sanction of the Authority to the application of the company for a provisional order to enable them to supply electricity within the Authority's district, and, in the event of the Board declining to sanction the application, that an interview be granted to the directors. It was stated that the Authority had given permission to the Morecambe Electric Company to supply electricity to the Sandylands district of Heysham, and that it was necessary to give notice of motion for a future meeting that the application should be considered. Mr. Stephenson gave the requisite notice, stating that he did not think the Authority should discourage anything of the kind. It was subsequently pointed out that if the Authority consented to the application it would prevent any other company supplying electricity in the district, whereupon Mr. Stephenson said he would oppose the application.

Cambridge.—The Paving, Drainage, and Lighting Committee of the Town Council have reported that they have had several interviews with Mr. W. M. Fawcett, architect, with reference to the amount to be paid to him in respect of the preparation of the plans and specifications for the electric lighting station which the Corporation proposed to erect, when it was intended that they should carry out the electric lighting installation themselves, and finally Mr. Fawcett had agreed to accept the sum of £250 in discharge of all claims against the Corporation for services rendered and for disbursements made by him on their behalf in connection with the electric lighting, and the committee recommend that his offer be accepted. Councillor S. L. Young moved, and Alderman Deck seconded, the adoption of the report. Councillor H. M. Taylor, in supporting the motion, stated that he thought Mr. Fawcett in accepting the sum of £250 in respect of the electric lighting station had behaved in a most liberal and most generous manner. The motion was carried.

Reading.—The Callender Bitumen, Telegraph, and Waterproof Company, Limited, of London and Erith, who are the manufacturers and contractors for laying the underground mains of the Reading Electric Supply Company, Limited, have commenced their operations. The type of mains adopted is concentric lead sheathed and armoured, the dielectric itself being jute fibre, impregnated with bitumen under heavy pressure. With this system of mains, which are complete in themselves, as despatched from the manufactory, no further protection in the way of pipes or brick culverts is required. The mains are laid direct into the ground, the cables possessing sufficient mechanical strength necessary to withstand all ordinary rough usage and heavy traffic without injury. Amongst the various towns at present supplied by this system are Richmond, Tunbridge Wells, Brighton, Ealing, Pontypool, Cheltenham, Worcester, Oxford, Wolverhampton, Ayr, and Glasgow. The underground mains of the South Staffordshire and Douglas and Laxey Tramway Company are also on this system.

Chester.—A special meeting of the Chester Town Council has been held to discuss a recommendation submitted by the Boating and Baths Committee to the effect that the Hop-pole Paddock should be selected as the site for public baths. The Council had many months ago adopted the Hop-pole Paddock, which is their own property, as the site for baths and electric light generating station, it being felt that the joint scheme could be worked more economically than two separate undertakings. A strong opposition developed against the proposal, however, in which the Duke of Westminster, Bishop Jayne, and the dean and chapter joined, the contention being that the proximity of the electric lighting station to the city walls and cathedral would be dangerous, a nuisance, and an eyesore. Recently, the Council decided to place the electric lighting works on Corporation property known as the Water Tower Gardens, whereupon the Boating and Baths Committee decided to urge the Council to select the Hope-pole Paddock as the site for the public baths alone. The recommendation has been adopted.

Windsor.—On the recommendation of the Electric Lighting Committee, the Town Council have decided that the town clerk be requested to publish the statutory notices of intended application for a provisional order to supply electrical energy to Windsor and Eton. A new electric installation company is about to be started at Windsor, in the High-street, under the style and name of the Windsor Electric Installation Company, engineers and contractors. They have secured the services of Mr. A. E. Farrow, late manager of the Windsor branch of Roger Dawson, Limited, as their engineer and manager. Mr. Farrow has in Windsor laid down the electric light plant at the White Hart Hotel, and was consulting engineer during the installation of the light at the Manor Hotel, Datchet. While with Messrs. Dawson he carried out the electric lighting at The Priory, Datchet, at the Bracknell Supply Stores, and at Clewer Park, the residence of Sir H. D. Gooch. Electric lighting is about to be adopted at Bourne End for Mr. R. C. Lehmann and Mr. Spencer Brunton, and for Mr. G. F. Adcock at Riversdale, Bourne End.

Eastern Extension, Australasia, and China Telegraph Company.—The gross receipts, including Government subsidies, have amounted in the half-year to £247,681. 2s. 4d., against £257,986. 13s. 5d. for the corresponding half-year of 1893. The working expenses, including £21,295. 16s. 5d. for cost of repairs to cables and expenses of ships, absorb £80,295. 3s. 10d., against £78,229. 19s. 3d. for the corresponding period of 1893, leaving a balance of £167,385. 18s. 6d. From this is deducted £3,940. 2s. 7d. for income tax, £32,488. 13s. 9d. for interest on debentures, debenture stock, contribution to sinking fund, and revaluation of currency balances, leaving £130,957. 2s 2d. as the net profit for the half-year. Two quarterly interim dividends of 1½ per cent. each, amounting to £62,500, have been paid for the half-year under review, leaving £68,457. 2s. 2d. to be carried forward. The loss resulting from the third year of working, ended April 30 last, under the Australian tariff guarantee arrangement, amounted to £12,384, half of which was borne by the guaranteeing Governments and the other half by the associated cable companies in

Digitized by Google

terms of the agreement. The general meeting of the Company will be held at Winchester House on Wednesday afternoon next.

Glasgow.—A beginning will be made early next month with the lighting by electricity of the Glasgow Corporation tramcars. Each car is to be provided with a couple of accumulators, weighing about 40lb. apiece, placed at either end of the vehicle. There will be four lights on every car, each of 8 c.p., two being placed inside and two outside. The inside lamps are to hang from the ceiling, while the outside lights will be poised on poles above the heads of the passengers. These outside lamps will be placed at the ends of the cars, and will serve the purpose of the bullseyes presently used, as the glass facing outwards will be coloured to correspond with the name board. The accumulators will only require to be charged once a day. The contract has been given to the Froggat Electric Lighting Company, London. Dynamos are being laid down at Paisley-road and Coplawhill stations, the two places where the electricity is to be generated. It is expected that by the end of the year all the cars will be fitted with the light. The Glasgow and South-Western steamer "Minerva" has been fitted with a search-light of 1,000 c.p. The object is to assist the steamer in taking the piers on the late runs.

Poole.—At a recent meeting of the Council the promoters of the Poole and Bournemouth Tramways wrote asking the Corporation to consent to an extension of the time in which the proposed trams were to be commenced. The Council, however, did not accede to the request. The Board of Trade, on being appealed to, granted the promoters three months' extension to enable them in the meantime to again approach the Town Council. This has been done at a meeting of the Corporation, when Mr. James Gordon Smith and Mr. D. Onslow, of London, representing the promoters, attended as a deputation. Mr. Smith reminded the Council that it was intended to have electric trams, and with the tramways to incorporate a scheme for the lighting of the town with electricity. Therefore, in asking the Council to reconsider their decision, the promoters felt that they were not doing anything detrimental to the interests of the town in any way, as they hoped to commence laying down the trams in January next. After a short discussion, in the course of which the Town Clerk pointed out that it would be necessary to rescind the resolution now on the books, it was decided that on the next agenda notice would be given that inasmuch as the promoters have given an undertaking that the work shall be commenced at the Poole end, and the construction of the trams to be commenced in January, the Council will consider the desirability of rescinding their former resolution. The town clerk is to write to the promoters and get the terms of their undertaking in writing before the next Council meeting.

Huddersfield.—Mr. Thomas Bland, at a meeting of the Town Council, called attention to the refusal of the Central Wards Committee to allow the Huddersfield Industrial Society, Limited, to carry wires across Buxton-road for the purpose of lighting by electricity the society's premises in John-street. The society, Mr. Bland said, thought they were not being fairly treated, considering that a firm in George-street had been allowed to carry across an overhead wire there. Mr. Inman said that the committee had every desire to meet the wishes of the society as far as was practicable, but he pointed out that the traffic in Buxton-road was greatly in excess of that in George-street. Alderman Glendinning said that he should move that no overhead wires be allowed in any thoroughfare. Alderman Hellawell said he believed that if the application had been made to lay wires underground there would have been no objection. Alderman Stocks reminded the Council that if the request were acceded to, the Co-operative Society would enjoy a privilege which the Council did not enjoy themselves. The Council were compelled to lay their electric lighting wires underground. It would create a new danger if they were carried overhead. On the suggestion of Mr. Inman, Mr. Bland withdrew his opposition to the committee's record, and the minutes were adopted. The County Council have decided to inform the Central Wards Committee that there is no intention to lay mains along Viaduct-street at present. A supply of 500 3in. and 500 2in. pipes was ordered.

Luton.—At a special meeting of the Highways and Lighting Committee the clerk reported that he had received replies from 51 boroughs to the queries forwarded to them, and that he had sent to each member of the Council a tabulated statement of the queries and answers and also to the town clerks who had so courteously replied to the questions. The clerk also reported that he had had an interview with one of the chief officials of the Board of Trade and a firm of parliamentary agents, and gave full detailed particulars as to the proceedings to be taken and the probable expense of obtaining a provisional order, and generally on the whole question. The committee having very fully considered and discussed the whole question, the Mayor proposed, and Councillor Wilkinson seconded, the following resolution: "That the town clerk be and he is hereby authorised to take all legal and other steps to lead to an application being made to the Board of Trade for a provisional order for the supply of electricity for public and private purposes within the borough of Luton, in accordance with the provisions of the 'Electric Lighting Acts, 1882 to 1890,' and the rules made by the Board of Trade with respect to applications under the said Acts." The committee divided: ayes, 10; noes, 1. It was resolved that the clerk should retain Messrs. Sharpe, Parker, Pritchards, and Barham, of 9, Bridge-street, Westminster, London, as parliamentary agents in the matter of obtaining the provisional order. This report has now been before the Town Council, and has been adopted by a large majority.

Dover.—The Town Ward Lighting Committee of the Town Council have reported on the position of the arc lights from the Monument to the Market-square, and stated they did not approve of them, but as the position had already been settled they had no power to alter them. The Town Clerk said that the surveyor reported in April on the position, and after they had been referred to the Castle Ward Lighting Committee, they had been approved. Councillor Clark said that they were greatly disappointed, as the four lamps from the Monument were not placed in the most advantageous positions. He referred particularly to the lamp in front of the Monument, and thought that it spoilt the appearance of that structure. Councillor G. Mowll said that there were two lamps in the Market-square, one at the corner by the Fountain Hotel, and one by Mr. Igglesden's, but no provision had been made for a central lamp. It appeared that the positions had been selected by the electric light engineer, and submitted to the approval of the Council. The Castle Ward Lighting Committee had approved of the lamps in their district, but the four lamps in question in the Town Ward had been overlooked. The Mayor said that there had been some little misunderstanding, but he thought that they had best leave the lamps as arranged until they were tried, and then if they wished they could be altered. On the motion of Councillor Bradley, the lighting of the new streets on the Folkestone-road was submitted to the Town Ward Lighting Committee. Alderman Pepper also asked that the committee should report on the lighting of Cannon-street, and the question of electric light in these streets was ordered to be considered by them.

Cardiff.—A special meeting of the Lighting and Electrical Committee of the Cardiff Corporation was held at the Town Hall on Monday afternoon, under the presidency of Alderman P. W. Carey. A deputation, consisting of Messrs. John Gunn, Louis Tylor, and Mrs. Viriamu Jones, waited upon the committee upon the question of supplying electric light at the Aberdare Hall. When the application was originally made they understood that the minimum charge for the supply of the light would be £30 per annum, but, according to the draft agreement they were to pay £30 per annum plus the cost of the electricity consumed. If that agreement was adhered to they could not possibly take the light, as the cost would be too great. In the discussion which followed the Chairman pointed out that the Aberdare Hall was 1,200 yards outside the compulsory area, and the cost of laying the mains would be £600. Under the provisional order the Corporation were authorised to charge 5 per cent. on first cost of works outside the compulsory area. Mr. Riches stated that when the wires were once laid a number of people in Park-place would use the light, and the guarantee of the Aberdare Hall authorities could be reduced in proportion. Mr. Gunn said they were quite prepared to pay for all electricity above £30, but they could not afford to pay the two sums. Mr. Harpur here stated that in this district not a single application had been received for the light. Ultimately the deputation agreed to pay a minimum rate of £40 per year, plus the cost of electricity used beyond that amount, and on the motion of the Mayor, seconded by Mr. Gerhold, it was decided to lay the matter before the town clerk, in order to ascertain whether the suggestion could be carried out. A number of applications were read for the position of foreman of the electrical machinery and plant at the central station. The position is worth £3 a week. After going through the qualifications of the various candidates, Messrs. J. T. Elliott, J. E. Teesdale, J. Wits, and C. A. Hibbert were requested to appear before the committee yesterday. At a meeting of the Chamber of Commerce, the president announced that the Exchange Company were going to introduce the electric light for the convenience of the members of the Chamber.

Hanley.—Four 1,000-c.p. arc lamps are now employed to light Elphinstone's Circus. The Corporation met on Tuesday, when it appeared from the minutes of the Electric Lighting Sub-Committee that an application had been received from Messrs. McIlroy Bros. for electrical energy to supply 219 electric lamps at their premises in Miles Bank and Lamb-street, but the engineer reported that if the markets were lighted all the available energy would be taken up. The committee recommended that the application of Messrs. McIlroy Bros., also one from Mr. Handforth, Piccadilly, for a supply of 16 lamps, be complied with. It was further resolved: "That this sub-committee having found the existing plant and machinery insufficient to supply the demands for energy for electric lighting, tenders for an additional engine and alternator be obtained, and that the electrical engineer be requested to submit at an early meeting a scheme for the extension of the plant and mains for supplying the electrical energy likely to be required within the area of supply, that part of the scheme relating to the compulsory area being submitted for first consideration." The sub-committee also recommended that the town clerk be requested to write to the Brush Electrical Engineering Company requiring them to forthwith put the electric lighting plant and machinery in proper working order to the satisfaction of the borough surveyor in accordance with the terms of their contract. In moving the confirmation of these minutes, Alderman Shirley said the extent to which electrica energy had been applied for was phenomenal. All the power they were at present able to supply had been asked for, and the committee were, therefore, compelled to take steps with the view of providing additional plant and increased energy. The Board of Trade required them to retain surplus energy to the extent of 20 per cent., so that it was compulsory for them to provide extra power if they wished to meet the demands upon them. Mr. A. Wood, in seconding the motion, said it would have been better if the committee had got the existing plant out of the hands of the contractors before taking steps to provide additional plant, but, seeing that they had not sufficient power to light their markets now the wiring

Digitized by Google

was complete, the committee thought it desirable to proceed with obtaining further machinery without delay. The motion was then agreed to.

Medical Electrical Institute, Limited.—In this concern, which has just been registered, the word "electrical" is being used objectionably, and as the Official Receiver in Bankruptcy has virtually sanctioned the reconstruction, it will unfortunately have an official aspect to many of the lunatics in this kingdom who are not locked up. The title of the Company is the "Medical Electrical Institute, Limited," which has been registered by Jerome and Co., 38, Basinghall-street, E.C., with a capital of £75,000, divided into 25,000 7 per cent. preference shares of £1 each, and 20,000 ordinary shares of £2. 10s. each. Object: to purchase or otherwise acquire all the business, goodwill, rights, privileges, contracts, copyrights, trade-marks, patents, assets, and property of the Medical Battery Company, Limited; to adopt and carry into effect an agreement, made October 16, 1894, between the Medical Battery Company, Limited (in liquidation), of the one part, and H. Banyard, on behalf of this Company, of the other part; to provide for and carry out, under the control and superintendence of a duly qualified medical man, the treatment of diseases by means of galvanic, electric, and magnetic appliances, batteries, baths, medical and other apparatus, and by massage, hydrotherapic inhalation, mechanical exercise (Dr. Zander's, or any other system), chemical, dental, and other processes; and to carry on the business of manufacturers of and dealers in all kinds of galvanic electric, magnetic, therapeutic, gymnastic, and other appliances; as chemists and druggists, dentists, chiropodists, Turkish and other bath proprietors, etc. The first signatories to the memorandum of association are:

	Shares.
A. Cowen, clerk, 12, Charter-buildings, Goswell-road, E.C. ...	1
T. S. Smith, clerk, 80, Mallinson-road, Battersea-rise, S.W. ...	1
C. L. Quin, clerk, 64, Basinghall-street, E.C.	1
W. Brittain, clerk, 126, Windsor-road, Forest Gate, E.....	1
P. Jerome, solicitor, 7, Boutflower-road, Handsworth	1
T. J. Horrocks, merchant, 17, Goldhurst-terrace West, N.W...	1
A. Lienard, accountant, Newport Villa, Muswell-hill	1

There shall be six first directors. The first are C. G. Elers and J. Oliver (nominated by the ordinary shareholders), A. L. Poulter and L. J. Greenberg (nominated by the preference shareholders), and W. B. Jones and A. Fleet (nominated by the second mortgage debenture-holders). Qualification, 100 ordinary or 50 preference shares, or £100 second mortgage debentures. Remuneration, £600 per annum, or 5 per cent. of the net dividend profits, divisible. We can only hope that the money required will not be raised, and that the capital will be limited to the £17. 10s. put against the names of the signatory dummies. It is a pity that the concern in question has not been allowed to go into oblivion.

Whitehaven.—Mr. Rienzi Walton, one of the inspectors of the Local Government Board, has attended at the Town Hall, Whitehaven, for the purpose of making local enquiry in respect to the application of the Trustees of the Town and Harbour for sanction for further borrowing powers for the purpose of electric lighting. Among those present were Mr. J. G. Dees (chairman of the Trustee Board), Mr. J. Jacques, Mr. J. L. Paitson, Mr. J. Pattinson, Mr. T. K. Metcalf, Mr. J. Collins, Mr. J. Tyson, Mr. J. S. Brodie, Mr. E. Stiven, and Mr. P. J. Watts—all members or officials of the Trust. There were no unofficial ratepayers present. Mr. Brodie, the borough surveyor, gave evidence in support of the application, which was for power to borrow £6,304. About half of this was for works already executed, and the other half for works to be executed. The works already done were extras on the original contract, including extra public lamps for Hensingham-road, Arrowthwaite, and in the town, £492; extra domestic main round by Irish-street, £389. 2s. 11d.; three feeders to different points, £1,851. 10s. 2d.; extra domestic services beyond those sanctioned, £260. 5s. 10d.; wiring up of the harbour, £66 5s. 3d.; and cables in stock, £140. 6s. 8d. prime cost. Mr. Brodie explained that these works were urgently required, owing to the fact that the gas company might have charged the Trustees very heavily for the public lighting of the outlying district if they had not included them; and the extra plant was necessitated by the great demand there was for current beyond what it was anticipated there would be for some time. The additional plant now proposed to be acquired consisted of a pair of engines and dynamos, £1,500; water-pipes, £30; switchboards, alterations to connections and instruments, £60; conductors, branches, and house service, £1,750; meters £500; additional batteries, £50; sundries, £20. This was Dr. Hopkinson's own estimate. The whole of the public lighting of the town was now done by incandescent light. This was the only town in this country entirely lighted by electricity. There were 429 street lamps, equal to an average of 465 lamps of 16 c p. each. They had 104 harbour lamps, equal to an average of 172 16 c.p. lamps. There were 63 private installations, the total lamps supplied being 1,395 16 c.p. That brought up the total to 2,032 16-c.p. lamps now installed. The dynamo output at present at the station was 2,000 16-c.p. lamps, with a small battery equal to about 300 16-c.p. lamps for one hour. There were 3,400 lineal yards of domestic cable laid, and there was a lamp connection of one lamp to every 2·4 lineal yards. Applications had been received from 18 additional consumers These they could not accommodate without this further plant. They would equal 116 16 c.p. lamps. But he himself knew of many others that were pending. The applications were not sent in because it was known that they could not be met at present. Mr. Brodie gave the particulars of the financial position of the works that were submitted at the last trustee meeting. The Inspector remarked: It is satisfactory, I think, so far. Mr. Dees: I think so. Mr. Dees added that he need hardly say the Trustees were anxious to get sanction from the Local Government Board as early as possible.

Stafford.—The foundation-stone of the electric light station was laid last week by the Mayor (Councillor G. Wormal). The matter was first mooted by the service of a notice on the Corporation by the Electric Supply Association to the effect that they proposed to apply for power to supply the borough. As the owners of the gas-works, for which undertaking they had paid a considerable sum, the Corporation felt that they could not acquiesce in the application, and that if electricity was to be supplied in the borough they ought to supply it. Consequently, they applied for powers to do so, and obtained them in 1890. A canvass of the town was taken as to the demand for electric light, but there was not sufficient demand as to warrant the Council in spending some £15,000 capital outlay. The Board of Trade was apprised of these facts, and the matter lay in abeyance. On the erection, however, of the new County Council Hall the matter was reopened by the County Council applying to be supplied with the electric light for the hall and also for the technical schools now being built. On this a second canvass of those likely to require the electric light was made, and more favourable replies being received, Dr. Hopkinson, F.R.S., electrical engineer, was called in to advise the Council on the whole case His opinion was favourable to taking the work in hand. A Local Government Board enquiry was held, the result being that borrowing powers to the extent of £20,000 were granted by the Local Government Board. Of this sum it is proposed to spend only £15,000 at present. The contract for the main buildings was let to Mr. H. Lovatt, Wolverhampton, who is also the contractor for the county hall and the county technical buildings. The main buildings will be of red pressed bricks with Hollington stone facings, the interior of the dynamo-house being lined with glazed bricks. The dynamo-house is to be 82ft. by 45ft., and there will be three 120-h.p. condensing horizontal steam-engines, each to drive a dynamo, calculated to produce 300 amperes at 200 volts, with a speed of 600 revolutions per minute. Adjoining the dynamo-house will be a boiler-house, in which there will be erected three Lancashire steel boilers, 7ft. 6in. diameter and 28ft. long. Space is left in the dynamo-house for two more engines if necessary, and in the boiler-house for four more boilers. The chimney stack will be 135ft. high, with sufficient capacity to accommodate eight boilers. The cables will be enclosed in earthenware pipes. The supply will be on the three-wire system of Dr. Hopkinson. The stone-laying ceremony was performed in the presence of the members of the Town Council and a few spectators. Mr. J. F. Bell, gas engineer, presented a silver trowel and mallet wherewith to perform the ceremony Having done so, the Mayor declared the stone well and truly laid. Alderman W. H. Peach, chairman of the Electric Lighting Committee, proposed a vote of thanks to the Mayor for performing the ceremony, and gave a history of the undertaking.

Hampstead.—The Electric Lighting Committee of the Vestry reported that they had insured the electric station building and plant in the Norwich Union Fire Insurance Society as follows: buildings, for £6,000, at 5s. per cent.; plant and other contents (exclusive of dynamos), £7,000, at 5s. per cent.; dynamos, £2,000, at 21s. per cent. without warranty; that they had insured the four boilers against explosion with the Boiler Insurance Company for £2,000 each at the annual premium of 40s. each, and the economiser also against explosion with the same company for £300; that they had considered applications for the supply of electric current in Heath-street, High-street, and Gayton-road, and they recommended that mains be laid from the sub-station No. 6 in Arkwright-road along Fitzjohn's-avenue and Heath-street to a new sub-station at the junction of Heath-street and High-street, and from thence along High-street and Gayton-road, at an estimated cost of £726; that the request of the committee of the Metropolitan Asylums Board to be supplied with electric current at their North-Western Hospital, at a reduction of 33 per cent. off the present price, be agreed to, provided the Board enter into a three years' agreement to take annually a supply of not less than 70,000 units; that the engineer be authorised to obtain certain tools, etc., required at the station, as set forth in a list submitted to the committee at a cost of £105. 4s. 7d., such amount to include the sum of £19. 18s. 8d. already expended on account of tools (as previously authorised); and that the engineer be authorised to obtain the necessary meters, etc., for customers' connections, at a cost not exceeding £300. In reply to the chairman, Mr. Thwaites, chairman of the Electric Lighting Committee, said that the price to be charged to the North-Western Hospital would be a little over 4d. per unit. Mr. Sharpe said that some time ago the Vestry decided that 20 per cent. was to be the highest discount allowed. Why was 33 per cent. to be allowed in this case? Mr. Underwood replied that this deduction was in strict accordance with the scale already agreed upon. Twenty per cent. was to be allowed on an amount of £500. Here it was expected that the sum of £1,100 would be received from the hospital. Mr. Greenhill thereupon moved, as an amendment, and Mr. Payne seconded, that the clause be sent back to the committee with instructions to them to negotiate with the hospital committee for the supply of the light on the basis of 4d. per unit. Mr. Thwaites expressed his willingness to accept this amendment. The recommendations of the committee were adopted, with the exception of this clause referring to the supply to the hospital, which was referred back in accordance with the terms of Mr. Greenhill's amendment. A cheque was drawn for £300 in favour of Mr. W. H. Preece, C.B., F.R.S,, the consulting engineer, for commission on the sum of £6,000 certified on account of Messrs. Siemens's contract. The consideration of the following recommendation of the Electric Lighting Committee, submitted on July 26,

Digitized by Google

was resumed—viz., "That application be made to the London County Council to advance to the Vestry the sum of £24,400 for electric lighting purposes under the terms of their order, dated June 26, 1894." The motion was agreed to. The Works Committee reported that they had instructed the surveyor to remove the 38 gas lamps superseded by the electric arc lamps in the Finchley-road, upon receiving an intimation from the electrical engineer that they are no longer required. Approved.

Birmingham.—The installation of the electric light at the Market Hall was brought into use on Tuesday evening, when the current was turned on by Councillor Parkes (chairman of the Markets and Fairs Committee) in the presence of a large company of persons interested in the improvement. Among them were Councillors Jarvis, Bowkett, Nixon, Moore Bayley, Marsh, and S. Lloyd; Mr. Henry Lea (Messrs. Lea and Thornbury), and Mr. Vaudrey (manager of the Electric Supply Company). The installation consists of 42 arc lights and three incandescent lamps for the superintendent's office. The lamps, with the exception of those illuminating the entrance, are suspended over the gangways of the hall, at a height of 14ft. from the floor, and the light, amounting in the hall to about 50,000 actual candle-power, is well distributed throughout the entire space. The capital outlay amounts to £900, which will be repaid by annual contributions for 10 years of £100 per annum. The cost of running the electric lamps will be £507 for energy and £25 for carbons, as compared with £522 at present paid for gas. The gas lighting hitherto has been very unsatisfactory, and upon enquiry it was found that to improve it would involve a materially greater cost than the employment of electricity from the mains of the Electric Supply Company. The turning on and off of the lamps is effected by a switchboard in the superintendent's office. This board contains 23 switches, each of them governing two lamps, and these are turned on slowly, one after the other, so as not to make too sudden a call upon the supply company's mains. Councillor Parkes, having turned on the light, addressed a few remarks to those who were present. He said it was 61 years since the foundation-stone of that hall was laid, and at no period of its history had it been so brilliantly illuminated as at the present time. When the Markets and Fairs Committee decided upon the employment of electricity they were subjected to some severe criticism, but he thought they would agree with him that they were right in the course they had adopted. He quite admitted that gas was a most useful illuminant under some circumstances, but for a building of that kind the electric arc light was certainly very much the best. The nominal candle-power that he had now lighted was something like 100,000 candles, but the actual candle-power was little more than half that in consequence of the medium through which the light came. He only wished he could turn on good trade as easily as he turned on the new lights. Unfortunately, that was not in his power, but he thought that by providing improved illumination for the hall they would render it additionally attractive, and that an increased business would be done there. The wish of the committee was to make the building as well adapted to the business of the tenants as they possibly could, and he felt sure the tenants would be pleased with the improvement. He believed the Birmingham Market Hall would always command a large amount of attention from buyers, not only resident in Birmingham, but also from visitors from the surrounding districts. He wished success to the market, and to all who did business in it. Councillor Jarvis (chairman of the General Markets Sub-Committee) said that the committee thought it well to bring the market up to date in respect to its illumination. The electric installation had been most successfully carried out by Messrs. Lea and Thornbury, and the Council were specially indebted to Mr. Henry Lea for the attention which he had devoted to it. He also mentioned that they had been met in a most generous manner by Mr. Vaudrey, on behalf of the Electric Supply Company, and also by the Walsall Electrical Company in respect to the necessary fittings.

Ulverston.—The following report has been brought before a meeting of the Rural Sanitary Authority: At a conference of representatives of the Ulverston Union Rural Sanitary Authority, the Dalton, and Grange, and Ulverston Local Boards held on the 4th inst., Mr. James Hodgson presiding, the clerk of the Ulverston Rural Sanitary Authority laid before the committee notice of the Windermere and District Electric Supply Company, Limited, of their intention to make application to the Board of Trade in pursuance of the Electric Lighting Acts, 1882 and 1888, for a provisional order authorising the company to supply electrical energy for public or private purposes within the area of the jurisdiction of the local authority as defined by the above Acts for the district of the Ulverston Union Rural Sanitary Authority. The Grange and Ulverston Local Board representatives intimated that their respective Boards had received a similar notice. The Dalton representatives stated that no such notice had been served upon their Board, and withdrew from the conference. Moved by Mr. Haines, seconded by Mr. Tosh, and resolved, "That the committee consider that it would be reasonable that the Windermere and District Electricity Supply Company, Limited, should have the power to supply electrical energy for public or private purposes to such portion of the Ulverston rural sanitary district as extends to Haverthwaite, including the watershed of the Leven on the west as far as Greythwaite, and the portion of the rural sanitary district on the east side of the River Leven, and the district of the Grange Local Board, should the before-mentioned portions of the said district and the Grange Local Board consider it desirable to have the use of the electric light within the said districts, and that the Ulverston Rural Sanitary Authority oppose the application of the order to the rest of their district, along with the Ulverston Local Board, and that if the part of the Ulverston Rural Sanitary Authority district to the north and east of Haverthwaite and the Grange Local Board do not desire to have electrical energy supplied by the said company, they be requested to join in opposing the proposed application. The committee also consider that it is desirable to appoint a sub-committee of seven members of this committee to meet and discuss the matter with electric supply company in the interests of all the parties concerned, and report to this committee." Mr. Haines, in the absence of Mr. Hodgson, moved the adoption of the report. Mr. Dove dwelt upon the importance of an assurance being given that the company did not intend to interfere with the waters of Coniston Lake. He did not think that any private company should have a monopoly in regard to that watershed. The Clerk: That is really what the committee propose to oppose. They wish to keep the company out of the Coniston district altogether. Mr. Mason seconded the motion. Mr. Harrison asked why the committee did not propose to oppose the company in regard to their powers on both sides of the Leven? Mr. Haines said there were two reasons. The first was, that if they entered a general opposition to everything the company asked for, the probability was the company would also oppose the Authority, and it was thought better to give the company a certain area, as defined in the report. The second reason was that the people of Haverthwaite, Cartmel, and Grange might wish to have the electric light, and they thought they should allow them this opportunity of getting it if they wished. Mr. Harrison did not think they should give a monopoly to any company without due consideration. The people of the places mentioned might be able to supply themselves on easier terms than they could obtain from a company with a monopoly. Mr. Haines: The committee came to the conclusion there was no other source of supply except the water power which this company has already purchased at Backbarrow. The Chairman said if the Cartmel and Grange Boards should upon consideration decide to oppose the application of the company, there was nothing to prevent the committee's report being modified accordingly. He suggested that the report should simply be read, and that the Authority should await the report of the conference with representatives of the company. This was agreed to.

Aberdeen.—Prof. Kennedy reports as follows to the Town Council with reference to the necessity for an extension of the electric lighting plant: "In July, 1892, I reported to you on this matter, and in March of this year the electric lighting works, carried out on the lines of my report, were opened. You may remember that in my report I estimated the total cost of the works, so far as the supply of the eastern district was concerned, at £24,400. I find from particulars furnished to me that the capital cost of the works, including all sums contracted for but not yet paid or due to the contractors, and including also the purchase price of the site in Cotton-street, the cost of connecting up consumers and of meters and every other matter covered by the estimate, along with the engineer's commission, amounts to about £23,900. The total cost is thus well within the estimate. Being exceedingly anxious not to give you too sanguine an estimate of the rate at which the lamps would be connected, I only put down the total number at 7,000 (in the eastern district) after two years of working, and provided plant for this number, although the station and the mains were so arranged that demands for increased power could easily be met as they arose. It must be most gratifying to you to find that the demand for lighting has increased far more rapidly than I ventured to suggest, and that already nearly 7,000 lamps are connected to your mains, although the station has only been at work for six months. It is not possible, from the running power of the summer months only, especially in a place so far north as Aberdeen, to estimate the probable income per lamp per annum. In my report I put it at 9s., assuming that you charged 8d. per Board of Trade unit. With your actual charge of 7d. per unit, this figure would be more nearly 8s. per lamp per annum, and I see no reason to suppose that this is an over-estimate. It corresponds to an average consumption of only 13·5 units per lamp per annum, as against 18 in Glasgow, 16·5 in Birmingham, 16·7 in Hull, and over 20 in Newcastle. From Mr. Murray's weekly station reports, of which I have sent you an analysis month by month, there seems every reason to think that even in your first full year of working the enterprise will fully pay its way without making any call on the rates, although it was hardly to have been expected that so favourable a result should be so soon obtained. It is undesirable that lamps should be connected in excess of the number for which the existing plant will safely provide current without use of the reserve plant, and this limit is now practically reached in the Aberdeen station. I have, therefore, to advise you that tenders should be obtained as soon as possible for the next instalment of the plant for which the station was schemed. This addition should consist of two engines and dynamos, each of about 200 h.p., placed on the existing engine-block in the places already provided for them. By this extension the total horse-power of the station will be raised from 316 to 716, and the net power (with one larger engine in reserve in each case) from 236 to 516. At present the maximum number of lamps (8 c.p.) which can be lit at one time (without use of reserve) is about 4,000, which is as many as there is any likelihood of being lit at once out of 7,000. The new plant would increase this to about 8,600, which would represent about 15,000 wired, or more than double the capacity of the present plant, besides allowing a larger reserve power. The present boiler power is sufficient for this extension, so that no new boilers would be required. Nor would any addition or alteration to the buildings have to be made—the present engine-house being large

Digitized by Google

enough to hold easily 400 h.p. more than this first extension, or still more if it should be found advisable later on to adopt a larger size of machine. With the new plant there will of course be required additions to the existing steam and exhaust pipes, etc., as well as additions to the instruments on the switch-board. In each case the existing work has been schemed so that further plant can be added without alteration to that which already exists. The present chimney, which is an old one, with some addition made to its height, will suffice for the new plant. I estimate the total additional cost of the two engines and dynamos, with all steam and exhaust pipes, switchboard instruments and connections, erected complete in the station ready for work, to be not more than £3,500. It would be advisable at the same time to increase the amount of copper in the feeders, as they will have to carry current increased in proportion to the increased power of the station. Provision was made when the mains were laid for making this increase as far as possible without lifting the road or foot-ways, so that it will be hardly anywhere necessary to disturb the surface of the streets. The cost of this additional copper, including the cost of pulling it into the culverts and connecting up, should not exceed £350. My estimate for the total cost of the extension to plant and mains is therefore £4,350. This, added to the amount already expended or contracted for, would bring up the total capital cost of the electric lighting scheme to about £29,000. In cases of this kind, the cost of the first instalment of buildings, foundations, plant, roadwork, and mains is, of course, far greater in proportion than the cost of extensions, so that the capacity of plant and mains is in this case more than doubled by an addition of less than 20 per cent. to the original cost. I have not entered into the question of the extension of the distributing mains—*i.e.*, the extension of the area to be lighted. This is an important matter of policy in which you must, no doubt, be guided very largely by the feelings of the inhabitants of the districts concerned. I have no doubt whatever that before long it will become necessary for you to extend the mains into at least as much of the western district as was shown on the map accompanying my original report. Whether this should be done in the summer of 1895 or not is a matter of which I am not able to advise you at this moment, as I have no information as to the existing or probable demand for current in the residential part of Aberdeen." In a note, Prof. Kennedy adds, "The maximum number of lamps which have as yet been alight at one time is about 3,500, on the 11th inst."

PROVISIONAL PATENTS, 1894.

OCTOBER 15.

19560. **Improvements in the means of transmitting power from gas-engines, steam-engines, and the like for driving dynamos and other apparatus.** Frederick Henry Royce, 53, Arcade-chambers, St. Mary's Gate, Manchester.

19585. **Improvements in electric arc lamps.** Pierre Adolphe Mougin, 28, Southampton-buildings, Chancery-lane, London.

OCTOBER 16.

19603. **Improvements in ceiling roses, cut-outs, and such like for electrical purposes.** Charles Leigh Clarke and William Paul Theermann, 7, South-parade, Manchester.

19605. **Improvements in electrical conductors and joints therefor.** Bond Andrews, 12, Batoum-gardens, Brook Green, London.

19654. **Improvements in telephone receivers.** Francis George Bell and Max Binswanger, 73, St. Stephen's-road, Upton Park, London.

19668. **Improvements in carbons or electrodes used in arc lamps for electric lighting.** Alfred Francis Bilderbeck Gomess, 9, Warwick-court, Gray's Inn, London.

19681. **Improvements in coin-freed telephonic apparatus.** William Miller, 28, Southampton-buildings, Chancery-lane, London.

19702. **Improvements in accumulators.** George Edward Heyl, 23, Southampton-buildings, Chancery-lane, London.

19710. **Improvements in dynamo-electric machines and motors.** Illius Augustus Timmis, 2, Great George-street, Westminster.

OCTOBER 17.

19733. **An electric clock.** Walter Hearn and Charles Robert Gatehouse, 32, Bow-street, London.

19742. **Improvements in electrical switches.** William Paul Theermann, 70, Deansgate, Manchester. (Complete specification.)

19764. **Charging electric accumulators.** John Hopkinson, 5, Victoria-street, Westminster.

OCTOBER 18.

19807. **Improvements in and connected with electric door contact.** Hermann Oppenheimer, 55, Redcross-street, London.

19842. **Improved electric storage fuse distribution box, also relating to single and double pole fuses or cut-outs.** Leon H. Cline, Buddle-street, Wallsend-on-Tyne.

19868. **An improvement in electro-deposition of an alloy of zinc and cadmium.** William Arthur Thoms and William Henry Burgum, 58, Lombard-street, London.

19889. **Improvements in electric arc lamps.** Charles Tyringham Praed and Percy Ruskin Allen, 46, Lincoln's-inn-fields, London.

OCTOBER 19.

19924. **Improvements in the combination of electric light with metallic bedsteads.** John William Hoyland and Wilson Henry Sturge, 12, Cherry-street, Birmingham.

19966. **Improvements in means or apparatus relating to the supply of electrical energy to portable electric lighting apparatus.** Henry Birnbaum, 55, Chancery-lane, London.

OCTOBER 20.

20017. **Improvements in the regulating mechanism of electric arc lamps.** Anthony George New and Arthur James Mayne, 55, Chancery-lane, London.

20043. **Improvements in arc electric lamps.** William Geipel, 73, St. Stephen's-road, Upton Park, London.

20059. **Casting by means of electric current.** Petro Scheidt and Jan W. Tideman, 26, Luisenstrasse, Berlin.

20081. **Improvements in rapid telegraphic transmission.** Charles Langdon-Davies, 24, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1893.

15971. **Electromagnetic motor.** Anders and Kottgen.

18150. **Secondary battery lamp for mines, etc.** Doubleday. (Sussmann.)

21435. **Electric heating bodies, etc.** Schindler.

21966. **Electrical drop indicator.** Beal.

22519. **Clips for electric conductor casings.** Darrah and Metcalfe.

22960. **Controlling electrical devices.** Wilkinson and Penson.

11973. **Electrolysis of water.** Siemens Bros. and Co. and Obach. (Second edition.)

1894.

4849. **Supporting and protecting electrical conductors.** Day and Allmark.

14634. **Galvanic battery.** Buell.

16400. **Generating and applying electricity to the body.** Newton and others.

NOTES.

Personal.—Sir David Salomons has accepted the mayoralty of Tunbridge Wells.

Telegraphy in India.—A line of telegraph is to be laid from Chittore to Oodeypur.

Telephony in France.—A telephone line has been inaugurated connecting Angiers with Paris *viâ* Saumur and Tours.

Cardiff Exhibition.—The council of the proposed exhibition have decided to postpone the holding thereof until 1896.

"Horncastle's Manual."—The sixth annual issue of this work will appear on January 1, and will deal with all matters relating to joint-stock enterprise in 1894.

Electric Towing.—According to the *Bulletin International de l'Electricité*, the experiments made on the Bourgogne Canal with electric towing have proved very successful.

Electric Traction in France.—A line of tramway between St. Georges-de-Didonne and Pontaillac, with a connection to Royan, has been declared of public utility.

Electric Cranes.—A description appears in the current issue of the *Bulletin International de l'Electricité* of a 15-ton electric crane which has been erected in the works of the Société Bollincx.

Electric Transmission in Germany.—The machinery of the Herzogl. Anhalt. Maschinenbau Anstalt und Giesserei, at Bernburg, is to be worked entirely by means of electric motors.

Southport Electricity Works.—The central electric light station established by the Southport Corporation will be opened by the Mayor (Alderman James Wood) on Friday next, the 9th inst.

Telegraphy on the Caspian Sea.—The Russian Government are establishing telegraphic communication between Astrachan and the so-called "12ft. roadstead," the anchoring place of vessels.

Electric Traction in Italy.—The Società Generale di Elettricità are asking the Milan Municipality for a concession for various lines of electric tramway through the main streets of the city.

Economy in the Use of Current.—A self-regulating switch has been devised for the purpose of automatically switching off in half an hour a lamp in case it is left alight when not required, a matter of importance to hotel keepers and others.

A Substitute for Indiarubber.—According to the *Echo*, whose "news," as a rule, is more extensive than accurate, "bolata, the product of a tree in Sumatra, is becoming the rival of Indiarubber and guttapercha." We never heard of it.

Royalty and Electric Light.—An electrical engineer crossed to Calais on Tuesday evening by the cargo boat with apparatus with which to light by electricity the special saloon in which the Prince and Princess of Wales are travelling across the Continent to Livadia.

The Electric Barber.—An American contemporary says that an ingenious citizen of Tacoma has devised an apparatus in which the principle of the electric fan is utilised to blow a current of warm air through the locks of a customer who has been having his head shampooed.

Telephony in Germany.—Delays have taken place in connection with the erection of the telephone line between Berlin and Vienna owing to difficulties which have been met with in Austria due to the nature of the ground. However, the line will, it is expected, be completed about the middle of the month.

Electric Lighting in Italy.—Experiments in connection with the electric lighting of the Milan streets having proved very satisfactory, the Società Generale di Elettricità are erecting a number of 500-c.p. arc lamps. The Municipality of Eboli, a small town in the Campagna, have decided to introduce the electric light there.

Electric Traction in Russia.—A decidedly novel project has been put before the St. Petersburg Municipality by the Finland Passenger Steamboat Company. They propose during the winter to run an electric tramway on the ice on the Neva, from the Palace Quay to the Mytninski Quay. Each car is to carry 20 passengers, the rate of speed being 20 versts per hour.

New Ink Slinger.—"Oh, my dear young man," remarked an old lady at an electrical exhibition, "what beautiful ink-bottles!"—pointing to some dry batteries. "Madam," observed the attendant, "these are indelible ink-bottles." "I thought so," rejoined the old lady. "If I had only heard of them in my younger days I should have been a millionairess."

Siemens-Halske Cyanide Process.—It is reported from South Africa that the Siemens-Halske cyanide process is being adopted by the Metropolitan, May Consolidated, and New Crœsus, and the first results, apart from those already obtained at the Worcester works, may be expected in a month or two. The royalty has been definitely fixed at 3 per cent.

Cost of Indian Telegrams.—A proposal to considerably reduce the cost of telegrams between India and the United Kingdom has been received by the Government of India, says the *Indian Engineer*, but it is impossible for any answer to be given, as the matter is one in which the cable companies are mainly concerned, and the Government can take no action without their sanction.

Society of Engineers.—The next ordinary meeting of this society will be held at the Town Hall, Westminster, on Monday, November 5, when the adjourned discussion of Mr. T. W. Baker's paper on "The Utilisation of Town Refuse for Generating Steam," will be resumed and concluded. The annual dinner will be held at the Holborn Restaurant on Wednesday, December 12 next.

Telegraphic Communication with Alderney.—The island of Alderney is now isolated from the rest of the world so far as telegraphic communication is concerned, a rupture having taken place in the cable connecting Alderney with Guernsey. The break is about mid-channel, and it is said will not be repaired until next spring. This will be unfortunate for the inhabitants, as during the winter months the mail steamer "Courier" goes there only twice a week.

Presentation.—On Wednesday last, on the occasion of Mr. E. Putland's retirement from his position on the technical staff of Messrs. Johnson and Phillips, he was presented by his late colleagues and friends with a handsome gold watch and other smaller items to mark the esteem and the goodwill which he has so well earned during his 10 years' connection with the firm. Great regret was expressed amongst all Mr. Putland's colleagues, and he is followed by their very best wishes.

Electric Traction in Austria-Hungary.—The Municipality of Budapest have approved in principle of the proposal of the local horse tramway company to convert their lines into electric tramways. The plans which they have prepared have also been accepted as a basis of the scheme to be carried out. The company will increase its capital to carry out the work. Steps are being taken in order to convert the Prague tramways, which belong to a Belgian company, into an electric system.

Digitized by Google

Electric Light on the Cheap.—According to the *Elektrotechnischer Anzeiger* of Berlin, a M. V. Jeanty has arrived in Berlin from Paris to exploit his "galvanic element, 'Fulgar.'" The cost per hour is stated to be for a 6-c.p. incandescent lamp ·0024 of a penny; for a 10-c.p. lamp, ·004 of a penny; and for a 16-c.p. lamp ·0064 of a penny. Our contemporary satirically enquires why anyone should now build a dynamo or construct accumulators.

Meldrum's Forced-Draught System.—The system of forced draught as applied to boilers, and to which reference is made in the article describing the Bolton electricity works, consists in the delivery of air under pressure into the closed ashpit beneath the firebox by means of a steam jet and carefully-designed blower, which is illustrated in the article in question. The appreciation of the system is shown by the fact that in over 2,000 cases this method has been adopted with successful results.

Flexible Couplings.—In our issue of October 12, reference was made in the description of the electricity works at Worcester to the Snyers clutch used in the driving of two of the alternators simultaneously by both turbines and engines. At that time we were unable to give an illustration of this coupling, but a view of it will now be found in another column, in the article on "Gas-driven Alternators." The working of this form of clutch at Worcester will be watched with interest, especially as regards the cost of maintenance or renewals.

Lectures on Polyphase Currents.—A short course of lectures on polyphase-current working will be given at Finsbury Technical College, by Prof. Silvanus P. Thompson, on Mondays, at 8 p.m., through the month of November. The first lecture deals with polyphase generators; the second with the history and development of the rotatory-field motor; the third is devoted to the theory of non-synchronous motors; and the series concludes with some account of the tests on modern types of alternate-current motors, their construction, and methods of starting and regulation.

"Technical Education Gazette."—We have received from the London County Council a copy of No. 1 of *The London Technical Education Gazette, being the official circular of the Technical Education Board of the London County Council*, which, it is stated, has for its object the publication of the official announcements of the Board. With the impudence characteristic of the Council, the secretary of the T. E. B. touts for advertisements for this circular. No information is afforded as to whether this sheet with the brief title is to be published weekly, monthly, quarterly, or annually.

Vulcanised Fibre.—A new price-list of the vulcanised fibre supplied by Messrs. Mosses and Mitchell and Co., Chiswell-street, E.C., has been issued. This fibre is largely used for mechanical and electrical purposes. The hard vulcanised fibre is a good insulator in all dry positions. Among the variety of applications of this fibre may be mentioned in dynamos for commutators, magnet heads, etc., for switchboards and switch plugs, wall insulators, bases of telegraph and electrical instruments, press buttons, electric gas-lighting appliances, electric fire and burglar alarms, electric lamps, etc.

French Cable Companies.—The *Journal des Débats*, says a Reuter's telegram, makes the following announcement: "The Minister of Commerce, Posts, and Telegraphs, with the sanction of the Council of Ministers, has signed a decree, dated October 27, which authorises the French Paris New York Telegram Company to transfer to the French Submarine Telegraph Company the rights and charges of the concession granted to it on January 7, 1879, for the establishment of a submarine Transatlantic cable. This decision officially confirms and renders definite the amalgamation of the two companies agreed upon by the meetings of their respective shareholders."

Bankside Station.—Messrs. Willans and Robinson, of Thames Ditton, have received an order from the British Thomson-Houston Company for several large engines for the Bankside station of the City of London Lighting Company, which is one of the most important orders for electric lighting engines ever received in this country at one time. There are eight engines of 700 i.h.p. each, coupled direct to Thomson-Houston alternators, and we understand that the Thomson-Houston Company have received a complete order, of which they form a part, for engines, dynamos, boilers, pipes, exciter plant, etc. They have already at this station put down four Willans engines of 300 i.h.p. each coupled direct to their alternators.

Electric Lighting for Hospitals.—The use of the electric light in public buildings and institutions gains ground steadily, if slowly. In all new buildings of any size and importance it is becoming a matter of course that the system shall be installed from the beginning; but when it is a question of adaptation to existing institutions the balancing of expense against convenience, says the *Hospital*, gives matter for much deliberation, and too often hospital authorities are frightened to embark upon improvements, however important, when a very large initial expenditure is entailed. With the money difficulty once overcome, there cannot be two opinions as to the enormous advantages to be gained by its adoption.

Electric Lighting in France.—Good progress is being made by Mr. Andrieu in connection with his central electric light station at Capdenac, where the water power of the Lot will be utilised. Current will be supplied to the Capdenac railway station, to the Municipality, and to private consumers. Thomson-Houston dynamos and Fontaine turbines will be used. The gas company at Laval intend to offer the Municipality a proposal to erect a central electric light station. They have been authorised to use the Avesnières waterfall for motive power. A report has been submitted to the Lille Municipality with respect to the scheme proposed by the gas company for lighting some of the streets of the town by electricity.

Lancashire Jokes.—During the process of construction and equipment of a certain Lancashire central electric light station, some of the workmen on the job became curious about the electrical plant, and it was decided to give them a fright and those in the know a little pleasure. One instance was the painting on a large wooden box containing water of the words, "Danger: this box is charged with alternating currants" (currents). Another was the labelling of the words, "Beware of danger: this machine is being charged," on an alternator which was not run for some weeks afterwards. A third trifle was the advice given to "keep away from the engines [which were not running], or they would pull your watch out of your pocket."

Institution of Electrical Engineers.—The first of the meetings of the Institution during the session of 1894-95 will be held on Thursday, 8th inst., when the following papers will be read: "Notes on Electric Tram ways in the United States and Canada" (supplementary paper), by Mr. H. D. Wilkinson, member, and "Electric Traction, with Special Reference to the Installation of Elevated Conductors," by Mr. R. W. Blackwell, foreign member, and Philip Dawson, associate. These papers will be discussed, together with Mr. Wilkinson's original paper, "Notes on Electric Tramways," etc., published in Part 113

of the *Journal of Proceedings*. The annual dinner, as we have already stated, will be held at the Freemasons' Tavern on November 21.

Association of Municipal and County Engineers. A meeting of the Incorporated Association of Municipal and County Engineers will be held to-morrow (Saturday) for the purpose of inspecting the Colne Valley Water Company's works at Bushey, and also the Hampstead electric lighting station, which has been recently opened. The programme of the meeting will be as follows: 11.40 a.m.—train leaves Euston for Bushey, arriving 12.20; 12.30 a.m.—short paper describing the water company's works now in progress will be read by Mr. Brough Taylor, M.I.C.E.; 1 p.m.—lunch; 1.30 p.m.—inspection of pumping station and water-softening works; 2.34—train from Bushey to Hampstead (change at Willesden Junction); 3.30 p.m.—short paper upon electric lighting installation by Mr. W. H. Preece, C.B., F.R.S., etc.; 4 p.m.—inspection of electric lighting station and works.

Electric Torpedo Boat.—According to a Reuter's telegram from Melbourne, Mr. Seymour Allan, a resident of Sydney, has invented a submarine torpedo boat capable of sinking to any depth, and of travelling under water as quickly as on the surface without revealing its presence. A working model of the boat has been tried in the public baths in the presence of the Earl of Hopetoun, the Governor, the naval commandant, and a number of naval and military officers. The experiments were a complete success, the model rising or sinking stern or bow, turning, reversing, or remaining stationary in obedience to the electric current by which it is worked. The inventor claims that a full-sized boat would be capable of remaining under water for three days, and would carry torpedoes on the bow and stern decks. When fired the projectiles would be magnetically attracted to the bottom of an enemy's ship. What next!

Bordeaux Exhibition.—A meeting will shortly be held at the London Chamber of Commerce for the purpose of ascertaining to what extent British manufacturers and others are disposed to actively participate in the thirteenth National, International, and Universal Exhibition to be held in Bordeaux from May to November, 1895. With the object of making the meeting thoroughly representative, the secretary of the London Chamber will be pleased to forward a formal invitation to any interested persons who will intimate their wish to be present. Meanwhile, the full regulations and other information as to the exhibition may be obtained on application at the offices of the Chamber, Botolph House, Eastcheap. Should the meeting come to a conclusion in favour of British participation, it will be part of the business to nominate the members of a British committee, on lines similar to those pursued in regard to the Antwerp Exhibition of this year.

Berlin Electricity Works.—The Electrical Company, of 122 and 124, Charing Cross-road, inform us that the report for the year 1893-94 of the Berliner Electricitätswerke contains the following figures up to the end of September, 1894: Consumption of current supplied to the cable network, 97,287 amperes; additional consumers to the extent of an output of 9,313 amperes will be shortly connected to the mains. The consumption of current during the year 1893-94 was equal to 92,055,000 normal lamp-hours for private customers, and 424,290 for street-lighting; and for motors, 570,421 kilowatt-hours were used. At the end of June, 1894, 360 motors were connected with an output of 1,364 h.p., and orders for 70 more motors, with an output of 300 h.p., are in hand. The total capacity of the station is over 13,000 kilowatts. The Berliner Electricitätswerke were designed and constructed by the Allgemeine Electricitäts-Gesellschaft, of Berlin, whose sole agents for Great Britain are the Electrical Company, Limited.

The Mica Mines of Chota Nagpur.—The mica mines worked in this part of India are all situated in the Giridih sub-division of the Hazaribagh district. The majority of these are in the Kodarma Government estate, both inside and outside the Government reserved forests, and the rest are scattered over portions of *gadis* Gawan, Domchanch, Khesmi, Musnudih, Byrea, Doranda, and Satgawan. The majority of the mines situated within the above-mentioned *gadis* are worked by Messrs. Christian and Company. During the past year 15 new mines, covering an aggregate area of 22·57 acres within the Kodarma Government estate, were settled by the deputy commissioner of Hazaribagh at an aggregate rental of Rs.1,252 per annum. The aggregate current demand of the rent due to the Government amounted to Rs. 9,692, out of which Rs. 9,554 was realised, and only Rs. 137 remained due from one lessee. The total output of all the mines, whether situated within the Government estate of Kodarma, or in the estates of private zemindars, was 3,086 maunds 25 seers, against 2,236 maunds in the previous year.

The Pacific Cable.—A Reuter's telegram from San Francisco, dated October 27, says: "Mr. Mercer, of the British Colonial Office, and Mr. Sandford Fleming, the representative of Canada, have returned from Hawaii, where they have been negotiating with the Government of that country for the concession of a landing-place and telegraph station for the projected Pacific cable. Mr. Fleming was interviewed on arrival here, and said that the Hawaiian treaty with the United States precluded the concession of any land or any special rights to any country other than America. The British commissioners had agreed not to fortify the cable station nor to create a naval station. Mr. Fleming added that it was understood Hawaii would appeal to Washington for permission to grant the privilege asked for by Great Britain in respect to the land concession. The commissioners, while on their journey, inspected Bird Island, and made the necessary soundings in the vicinity. They will proceed from San Francisco to Washington to urge their case with the United States Government."

Engineering, Electrical, and Allied Trades Sections.—A meeting of these sections of the London Chamber of Commerce, and others interested in the construction of light railways and of steam and electric tramways, will be held at the offices, Botolph House, Eastcheap, E.C., to-day (Friday), at 2.30 p.m., to consider the following agenda: "(1) to consider a circular letter [which is given in another column] received from the Railway Department of the Board of Trade in reference to 'a movement recently set on foot with the object of obtaining further powers and facilities for the construction of light railways and steam or electric tramroads,' and to 'the requirements which are imposed by the Board of Trade upon new railways'; (2) to appoint two members to attend a conference at the Board of Trade on an early date with the object of discussing (*a*) 'how far the usual requirements of the Board of Trade as to constructing and working new railways may fairly be relaxed, especially in the case of lines built through sparsely-populated and agricultural districts'; and (*b*) 'whether additional legal facilities for obtaining powers to construct tramroads and light railways are necessary or desirable.'"

The New Decimal Association.—A general meeting of the members of the New Decimal Association will be

Digitized by Google

held at the offices of the London Chamber of Commerce on the 20th inst. It is intended, as soon as possible after Parliament reassembles, to move the appointment of a Select Committee, and it is chiefly for supporting this action that the meeting now called is to be held. It is also proposed that endeavours should be made to secure energetic action in the United States. The following resolutions will be submitted: "Resolved, that this association learns, with great satisfaction, that the Government no longer oppose the appointment of a Select Committee to enquire whether any, and what, changes in the present system of weights and measures should be adopted, and the executive committee is hereby authorised to take such steps as it may consider best for promoting the adoption of the metric weights and measures." "Resolved, that Mr. William L. Wilson be informed of the position of the movement in this country for adopting the metric weights and measures, and that he be urgently invited to use his influence to secure such legislation as may provide for the adoption of this system of weights and measures in the United States."

Use of Micanite.—The Mica Insulator Company, of New York, have issued the following concerning the use of micanite: An important point in making or refilling commutators is the necessity of applying heat during the process of building, and from long experience we will guarantee the following method to give perfect satisfaction, and be a cure for such ills as loose bars, cement oozing out, or oil soaking in, if micanite segments or rings are used. After assembling the commutator, heat it to about 200deg. F., or just enough to make micanite pliable, then tighten the bars or rings as much as possible. The pliability of the micanite will allow the distribution of unequal strains and will counteract to a great extent irregularities in the dimensions of other parts of the commutator. Then continue the heating, but this time let it reach 400deg. F., or until the shellac, which will have oozed out here and there, has become dry. In fact, the shellac may be partially carbonised with no bad results. Then retighten the commutator either hot or cold, but preferably in both states. Do not tighten during the progress of this second heating, but wait until the shellac is baked dry. When no proper arrangements are provided for heating, the commutator can be put for a few minutes inside a boiler-furnace door, or on a gasoline stove, or on a plate placed over a blacksmith's forge.

Calcutta Tramways.—The regularly recurring hot season, says *Indian Engineering*, brings in its train a list of casualties among the tramway company's horses in Calcutta, as well as other places where this system of locomotion is in vogue, which is heartrending. But apart from this, which is practically rather a shareholder's point of view, there is much to be advanced from the point of view of the public against relying upon beasts of burden for the regularity and certainty of their reaching their places of business, considering the value and increasing importance of every moment of time. In such centres as Calcutta, Bombay, Madras, etc., nothing short of mechanical power should be insisted upon for the working of tramways, since such power is unaffected by weather, and journeys may be timed with fair accuracy, which it is impossible to do when animal power is relied upon. The daily traveller by tram in Calcutta knows only too well by the stoppages which result from the use of too fresh or too stale horses just when pressed for time, or by the snail pace rendered necessary in the hot weather, what the inconveniences of the present system are, and he is fully entitled to have a grumble when he reads of electric and cable tramways adopted in places where nearly everything is in favour of animal power. There seems to be no potent reason why the tramways in Calcutta should not be converted into cable, if not into electric, tramways to the much greater convenience of the public using them.

Electric Traction in Germany.—A commission was sent by the Elberfeld Municipality to Paris to inspect the accumulator electric traction system there in connection with a proposed line at Elberfeld running north and south. The Railway Commission in consequence were in favour of arranging with Messrs. Mather and Platt, of Manchester, to carry out an accumulator project, but the Municipality at a private meeting have decided not to do so, but to give the work to the Elektricitäts-Gesellschaft "Union," of Berlin. Yet another scheme for an electric railway in Berlin has been laid before the Municipality, this time by Messrs. Kramer and Co., railway contractors. The line in question is intended for the purpose of establishing communication between the western and north-western districts, starting from the Genthinerstrasse and terminating at the Weinendammer Bridge. The local authorities of Berlin have granted a 40 years' concession to the Charlottenburg Horse Tramway Company for electric traction on their lines from the Alt-Moabit-strasse to the Lindenstrasse, *viâ* Paulstrasse and the Luther Bridge. The Grunderwerbs und Baugesellschaft, of Berlin, propose to construct an electric tramway on the trolley system between Landsberger Platz, Berlin, and Hohen-Schönhausen. It is proposed, when the central electric generating station is established in Dresden, that the three eastern lines of the Dresden Street Railway Company in Blasewitz, Striesen, and Strehlen, shall adopt electric traction on Messrs. Siemens and Halske's system. Mr. Th. Wulff has acquired the Bromberg horse tramway, with the object of converting it into an electric line. The work will be carried out by the Allgemeine Elektricitäts-Gesellschaft, of Berlin.

The "Intense" Cat.—A widening circle of admirers is loud in the praise of the cat. When the secretary of the National Cat Show assures us, says the *Lancet*, that the animal is "intense" it is quite possible to agree with him. When he adds the suggestion that gently rubbing a cat's back may "have a beneficial effect on persons in bad health" it is scarcely safe, in view of all that is known of "suggestion" and the effects of peripheral stimulation on nervous centres, to absolutely differ from him; but when it becomes evident that he deduces the above from what "everybody who has studied cats must know," that "the animal is full of electricity," it becomes difficult to repress a more or less emphatic request to him to "stop." The electrical effect produced by rubbing a cat's back is, of course, well known; it is also well known that this is frictional electricity, or, perhaps more correctly, the electricity of contact—that it is a surface effect produced by the rubbing, that it does not point to pre-existing electricity stored in the body of the animal, and that the person who, having concluded a massage, sinks into a chair declaring that his exhaustion is consequent on the loss of "the living galvanism" which he has imparted to the patient is a charlatan. It is to be remembered that friction between any dissimilar substances always produces electricity, and in illustration of this the electrical effect sometimes produced in a dry atmosphere when the hair is combed or the body quickly divested of a flannel jersey may be instanced, or the classic experiment of rubbing a stick of sealing-wax on a rabbit's fur may be called to mind. Those who are accustomed to rely on the curative effect of stroking a cat's back may find consolation in the last-named experiment, inasmuch as it teaches them that when their "feline favourite" is no more health and strength may still be secured by gentle friction on its skin.

Electricity in Australia.—An Australian correspondent writes to us that an electrical conference was to be held in Melbourne about the end of September for the purpose of drafting a code of rules governing the erection of overhead light and power wires. Mr. P. B. Walker, of the Telegraph Department, and Mr. Jas. O. Callender, were appointed to represent New South Wales. The North Sydney electric tram has broken down, the armature of the generator being burnt out. In the interim a small dynamo (which also broke down) was put in to run one car during the hours of light load, the heavy load being taken up by the trailers of the cable tram drawn by horses. The Telegraph Department have been considering the advisability of extending the Moore-street tunnel as far as the exchange. As this is rather an expensive undertaking, the Callender-Webber conduit was proposed. The result has been that nothing is to be done till the subject has been discussed by the conference to be held in Melbourne. The Hillgrove Electric Light and Power Company have at last started their installation at Hillgrove. The power is generated six miles from Hillgrove at Gara Falls, and the distribution is on the three-wire system. The company's programme includes the lighting of the town and motive power to the mines. Mr. W. Harcourt Palmer is the hydraulic engineer, and Prof. Threlfall, of the Sydney University, consulting electrician to the company. The contractors to the electrical portion are the Crompton Company, under the supervision of Mr. O. W. Brain. The Railway Commissioners have had an experimental accumulator tramcar built, which has been running between the Sydney railway station and the city since May last. The car carries 80 passengers, and is exceptionally heavy, weighing about 17 tons loaded. So far it has evidently been successful, and the Commissioners have ordered two more to be built on the same lines.

New Swindon Junior Engineering Society.—A successful meeting of this society was held in the Mechanics' Institution on Thursday last, when Mr. G. B. Clifton, M.I.Mech.E., read a practical paper on "Ship-Lighting by Electricity," to a large attendance. Mr. Clifton commenced with an enumeration of the advantage of installing the engine and dynamo in such a position that the heat of the boilers and the accumulation of coal dust, rolling of ship, etc., would have the least effect on their running. A distributing-board was described from which the mains are led off to the respective compartments of a ship, and special attention was given to the efficient connection between the compartments. As an example of this an ingenious type of stuffing-box which not only renders the joint watertight, but at the same time insulates the cable from the bulkhead, was submitted. Mr. Clifton emphasised the great necessity for providing good protection of the wires from the action of salt water, and their careful jointing, using resin as the flux, and also pointed out the advisability of the co-operation of the shipbuilder and the electrical engineer to facilitate the wiring of a ship under the best conditions. Mr. Clifton concluded his paper with an exhaustive description of the fittings on a ship, where they differed appreciably from those used in house-lighting. In the discussion, the chairman, Mr. H. G. Cotsworth, gave a short review of the introduction of the electrical lighting of ships, and mentioned the great influence the contracts of the Admiralty and other private firms had on the final establishment of the electrical engineering industry. He also enquired as to the objections to the use of arc lamps in the cargo-holds of ships. Mr. Leader, with some remarks on the development of ship-lighting, Mr. Stephens, with the suggested use of portable lamps in the engine-rooms, and Mr. Tincknell, with an enquiry as to current-carrying capacity of the cables used, also contributed to the discussion, which was concluded with some further remarks by Mr. Clifton on the points raised.

"The Electric Lady."—In the early years of the eighteenth century, whilst Du Fay and the Abbé Nollet watched with astonishment "the first sparks that were ever drawn from the living body," and long before Kruger had conceived the idea of electro-therapeutics, or Kratzenstein had given that idea form, electrical phenomena, says the *Lancet*, were attracting much attention. Many earnest experimenters were investigating the "thing" which, since the days of Gilbert, had come to be called "electricity"; philosophers were gaining a first insight into its possibilities; a new science was quietly winning its way. At the same time the less serious portion of the society of the period, aware of the newly-discovered phenomena, was amusing itself by "drawing sparks" as "electric rain," or "the electric star," or, perhaps, occasionally in the form of the "electric kiss." At the end of the nineteenth century electrical science has made an amazing progress—a progress, however, with which its more frivolous developments seem scarcely to have kept pace. They have, it is true, got beyond the stage of the frictional machine, but it cannot be said that the entertaining young man of the period yet knows how to conjure playfully with currents of "Teslaic" frequency or to amuse an audience by a skilful adaptation of the Hertzian wave. The "penny shocker" is, from the electrical standpoint, a painfully coarse experience of a coil current, and even "the electric lady" of these latter days is, on the whole, a very poor thing. "She is found to be so highly charged with animal electricity that when she immerses her hand in water anyone placing a finger in the bowl at the same time experiences a shock." About the latter there can be no question; the sensation is that of an unmistakable induction current. Neither is it to be denied that she is "charged with electricity." In other words, she is connected with one pole of a large coil kept carefully out of sight and hearing. She places her hand in water; a second person, standing "to earth," and doing the same, offers a passage to the current through the body, and a fall of potential is the result; but there is no obvious means of completing the circuit. This may surprise those who work only with the ordinary medical coil, but anyone accustomed to larger coils and to so-called "idle pole" work is aware that under such circumstances no metallic connection with the other pole is necessary. The circuit is completed *viâ* the body of the second person through the ground and so back to the second pole; and the more effectively the latter is "earthed" the more palpable will be the effects in question. This unpolar method is from its medical aspect something more than a mere experiment. It affords a very serviceable method of electrisation. If a person lightly insulated and holding an ordinary moistened electrode attached to one pole of the secondary of a large coil be touched on the forehead by a person standing "to earth," the former will experience a not unpleasant electrical sensation—an effect, however, scarcely perceptible on the arm. But if the "operator" places his foot upon the firegrate (thus making a better earth) the effect is stronger. If, however, the idle pole itself be well "earthed" by being connected to a gas or water pipe, then, if the person holding the electrode as above be insulated on glass and be touched as before on the arm, a distinct effect just short of muscular contraction is produced. By altering the amount of the insulation and varying the "earthing" of either pole a variety of electrical effects are obtainable. Muscular contractions of a widely varying strength and cutaneous stimulation of every degree of intensity may be thus secured,

MECHANICAL TRACTION FOR TRAMWAYS.

(Continued from page 447.)

Turning from questions of theory, construction, and working to those of cost—both initial outlay and operating expenses—our author considers, first, the conductor system, whether overhead or underground; second, the central station; and, third, the car equipments.

With regard to the expenditure necessary for the line, he estimates the average cost of network proper—that is, the poles, span wires, trolley wires, and all accessories—at from £640 to £770 per mile of single line, and from £1,024 to £1,280 per mile with iron poles as against the cheaper ones of wood. For a double line these prices will require increasing by £200 to £250 per mile. A bare copper return conductor, buried in the soil, will cost when in position from £150 to £200 per mile. The expense entailed by feeders will, of course, vary according as they are carried overhead or underground.

When the line does not exceed 2½ miles in length the cars may be run directly from the trolley wires, but for any length over and above this distance feeders become essential. If their size is but small, not exceeding that of the trolley wires, they may be carried overhead; but as the demand for current increases when the line is extended or developed, either their number or size must also be increased, and in such a case it becomes almost necessary to put them underground. Their price then is, of course, higher, as they must be well insulated and protected by a lead and metal covering, or by being carried in earthenware or metal pipes. Their cost will average from £750 to £1,000 per mile, laid in position, for a section equal to carrying 125 amperes at ordinary current density. Their lengths will vary, as a rule, from one-third to one-fifth of the network, according to the relative position of the latter with the central station. The total cost of an overhead system will therefore reach an average of from £1,300 to £2,000 per mile.

The expenditure necessary upon an underground or trolley system is much more costly, and the electrical work alone, it is said, may even involve an outlay of £12,000 per mile, not counting any sums spent upon the permanent way.

Taking next the central station, it is usual to calculate upon 1,000 to 1,200 square feet of heating surface in the boilers per car on the line, and similarly from 18 i.h.p. to 20 i.h.p. in the engines. [This seems far too high; from 10 h.p. to 15 h.p. in the engines per car on line being ample allowance on ordinary lines without excessive grades.] This gives about 14 or 15 kilowatts dynamo output per car, without the reserves, which, of course, must be also allowed for. The outlay upon plant of this capacity for a line employing from eight to twenty cars will average £450 per car, divided up thus: £250 for boilers, engines, and steam accessories; and £200 for dynamos and electrical details. Buildings, estimated on a basis of £3 to £4 per square yard, will come to about £120 per car. An extra allowance of 35 per cent. at least should be made in all these prices to cover the cost of reserve plant, so that the total outlay upon the central station will range from £720 to £800 per car in service.

With regard to the cars and their motor equipment, the author states that at first the tendency was to make these too light for efficient working under rough usage, and the more modern types are much heavier than those formerly built. Cars to hold 50 passengers, designed by the Thomson-Houston Company, weigh from seven to eight tons empty, and those for 30 passengers about five or six tons. The cost of the former are given as varying from £800 to £1,000 complete. They replace smaller cars weighing 3½ to 4 tons each, and costing from £200 to £280, so that the excess in weight to be really taken into account is from 3½ to 4 tons, and the extra cost from £600 to £720 per car. The smaller electric cars, with a seating capacity for 28 to 32 passengers, cost about £600 to £700 each complete, of which £450 to £480 represents the electrical equipment over and above what an ordinary horse-car would require.

Speaking generally, an allowance of 25 per cent. in the number of cars must be made by way of reserve stock and cars under repair, so that the outlay for the large cars will vary from £720 to £800 per car in service.

The total expenditure may now be summarised thus:

Overhead line: £1,300 to £2,000 per mile of line.
Underground line: about £6,000 per mile of line.
Fixed plant and rolling-stock: from £1,450 to £1,600 per car in service.

From these data the author prepares a simple table to show comparison between the overhead and underground, or conduit system; assuming the cost of rolling-stock, fixed plant, and material at, say, £1,520 per car in service, he obtains the following results, which may be left in francs and kilometres as they merely give comparisons:

PER CAR IN SERVICE.

	Cost of line			Total cost		
	1 car per km.	2 cars per km.	3 cars per km.	1 car per km.	2 cars per km.	3 cars per km.
Overhead	25,000	12,500	8,300	63,000	50,500	46,300
Conduit	100,000	50,000	33,000	138,000	88,000	71,000

In support of the figures herein quoted, the sums expended on the Marseilles-St. Louis Electric Tramway on the overhead system, are set forth; this line has a length of nearly four miles, and was erected by Messrs. Sautter and Harlé:

Permanent way		£14,400
Overhead system, etc.		10,000
Buildings	£3,400	
Fixed plant, etc.	7,800	
		11,200
Eighteen cars, complete		14,560
Offices, etc.		5,800
Miscellaneous		1,840
Total		£57,800

or about £15,000 per mile, and £3,200 per motor car.

The line at Brussels, running from the Place Roupe to La Petite Espinette, with a length of 6¼ miles (rather less than one quarter of which is double track) cost about £2,750 per car in service, or £4,500 per mile. The number of cars usually employed is about 10; the company owns 12 cars, two being in reserve. These cost in all £10,560, and have seating capacity for 35 passengers. The electrical plant cost £16,960, so that the entire outlay was £27,520.

(To be continued.)

EFFICIENCY OF DIRECT-CURRENT MOTORS.

Writing in the *Electrotechnische Zeitschrift*, Mr. A. Müller, Vienna, deals with the subject of calculating the power given off by direct-current motors. He states that the direct experimental determination of the performance of an electric motor necessitates the use of the Prony brake or of another form of measuring the work done by the machine. When we have such an appliance and the ordinary current and pressure meters at our disposal, we can ascertain by means of direct tests the relation between the mechanical energy given off and the electrical energy conveyed to the motor—that is to say, the efficiency for different loads. When that has been done we can, by means of tabular or graphically arranged results of tests, read off the electrical energy to be employed for a given load, and at constant pressure the current strength. The use of the Prony brake, the author states, means a loss of time, and, particularly with large motors, it is costly. With a view to to overcome these disadvantages, Mr. Müller cites the following indirect method of determining the mechanical work performed. When running without a load, we regulate the pressure at the terminals of the motor so that the latter runs at its normal speed. Thereupon we measure the necessary pressure and current required to maintain the motor at this speed. From the products of both we deduct the calculated loss in watts from the ohmic resistance of the armature, and we thereby obtain that particular work at no load which corresponds to the hysteresis of the armature iron, eddy currents bearing friction, and air resistance. The author then gives mathematical examples of this method, which he concludes yields more reliable results than the employment of the Prony brake.

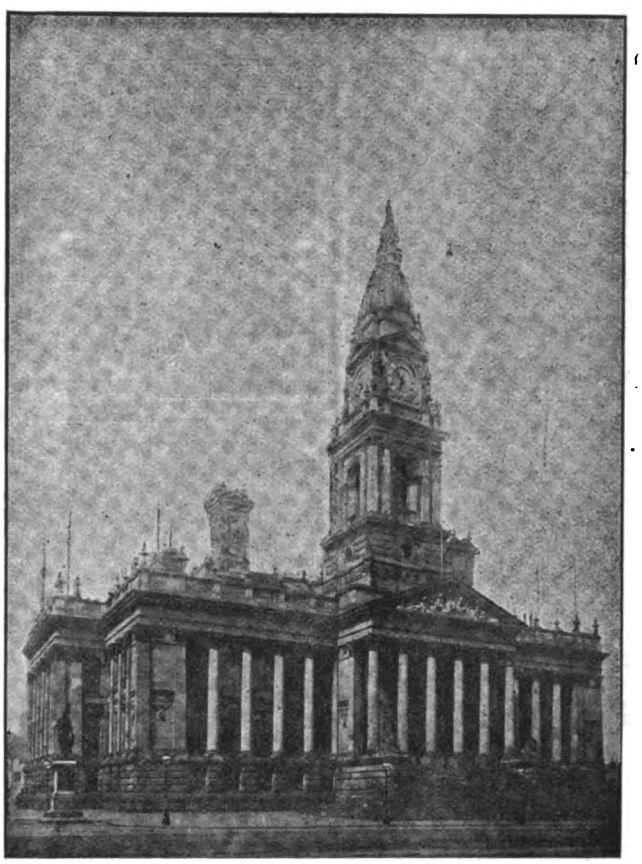
THE ELECTRICITY WORKS AT BOLTON.

General Remarks.

When one hears the name of Bolton, his mind always runs towards the manufacture of cotton, for is not this the staple trade of the town, where it has existed for several centuries. Its manufacture is, however, not of so ancient a character as that of woollen goods, which date back at least 700 years ago. Bolton is not Manchester, but through the inventions of Richard Arkwright and Samuel Crompton, it has largely—very largely—contributed towards the development of cotton manufacture in Lancashire. It is, however, not only for cotton spinning and manufacture that the town is celebrated, but engineering works and machine-constructing shops, together with bleaching and dyeing works, and iron and steel production, have made the town famous. The town has a population of some 116,000 persons, and its cotton manufactures and engineering and machine productions are to be found in all parts of the world.



BOLTON TOWN HALL.

The members of the Corporation are progressive, and they believe in concentration and municipalisation. In 1850 the authority of the Corporation was consolidated, and in 1864 an Act was obtained authorising extensions in the water supply and the provision of a public park and town hall. Bolton Park was opened in 1866, and the handsome Town Hall, of which a view is annexed, was inaugurated by the Prince and Princess of Wales in 1873. Not content with dealing with the water supply of the town, the Corporation in 1872 acquired the undertaking of the Bolton Gas Company. Sewerage works have been constructed at Burnden, and many important street improvements have been carried out. The town is provided with a market hall, wholesale market, free library, and an important technical school, whilst 17 miles of tramways, owned by the Corporation and leased to a company, are laid in the town and adjacent districts.

Another important step was taken when the Corporation, resolving to keep abreast of the times and not to be behind other corporate bodies, decided to municipalise the supply of the electric light, and the works for this purpose are now being set in operation. It will be subsequently seen that a new departure has been made, in so far that the capital outlay on the works has as far as possible been restricted to local firms. In fact, it is doubtful whether there is another town in the country where so much money has been spent locally on an enterprise of this character. However that may be, the Bolton Corporation were well advised in resolving to institute municipal electric light works, and were fortunate in securing Mr. John H. Rider, M.I E.E., as their electrical engineer.

As far as the adopted system is concerned there seems to be little that is novel, the method being high-pressure generation and low-pressure distribution on the three-wire system. It is, however, in the details which have been carefully thought out by Mr. Rider that some interesting and new features are to be found. As, however, these points will be considered further on, we may as well pass on to consider the early steps taken with a view to the introduction of a public supply of electricity. Why, it may be asked, should the Bolton Corporation establish electric light works? Let us see.

Preliminary Steps in Electric Lighting.

The Gas Committee of the Corporation in June, 1889, appointed a sub-committee to consider the subject of electric lighting, and subsequently notices were received from several companies intimating their intention to apply for parliamentary powers for the supply of electricity in the borough. As a result, it was determined, in view of the possibility of the Corporation themselves undertaking such a supply, to oppose the acquisition of powers for this purpose by any outside company, a fact upon which the Corporation are to be congratulated. In May of the following year, after obtaining information as to the action taken in the matter by other important municipalities, the Corporation decided to apply for a provisional order. A provisional order for this purpose was obtained, and this was confirmed by the Electric Lighting Orders Confirmation (No. 1) Act, 1891.

Consequent upon thus securing the requisite powers, the Gas and Lighting Committee, in November, 1891, appointed a sub-committee to carry them out. This sub-committee consisted of Alderman Miles (chairman), Alderman Broughton (vice-chairman), and Councillors W. Cooper, Finney, Tootill, Horridge, and Horrocks.

The first report of this sub-committee, presented in May of the following year, detailed the information sought and obtained by them on the subject, and recommended that contractors should be invited to furnish the Corporation with specifications and tenders for the installation; the generating station to be erected on land belonging to the Corporation in Spa-road; the area of supply in the first instance to be the compulsory area prescribed by the provisional order, but regard to be had to such further extensions as might be required to any other part of the borough. As a result, specifications and tenders were received from six firms, with estimates of the cost of the necessary plant, each firm recommending a system to be introduced. The sub-committee then visited towns where the systems recommended were to be seen in operation, but before coming to a final decision they appointed Mr. J. H. Rider as electrical engineer, and requested him to examine the specifications and advise the Corporation thereon. A report was then presented setting forth the conclusions of the sub-committee, and recommending the adoption of the alternating-current high-pressure system

Digitized by Google

with transformers, the engineer submitting a scheme for that purpose.

This report was approved by the Council, and the town clerk was directed to apply to the Local Government Board for permission to borrow £40,000 for electric lighting purposes. A Local Government Board enquiry into the matter took place on August 2, 1893. The detailed estimate of cost submitted at the enquiry showed that for initial requirements the sum of £22,695 would be needed, and that for prospective requirements further amounts would be necessary making a total of £41,650.

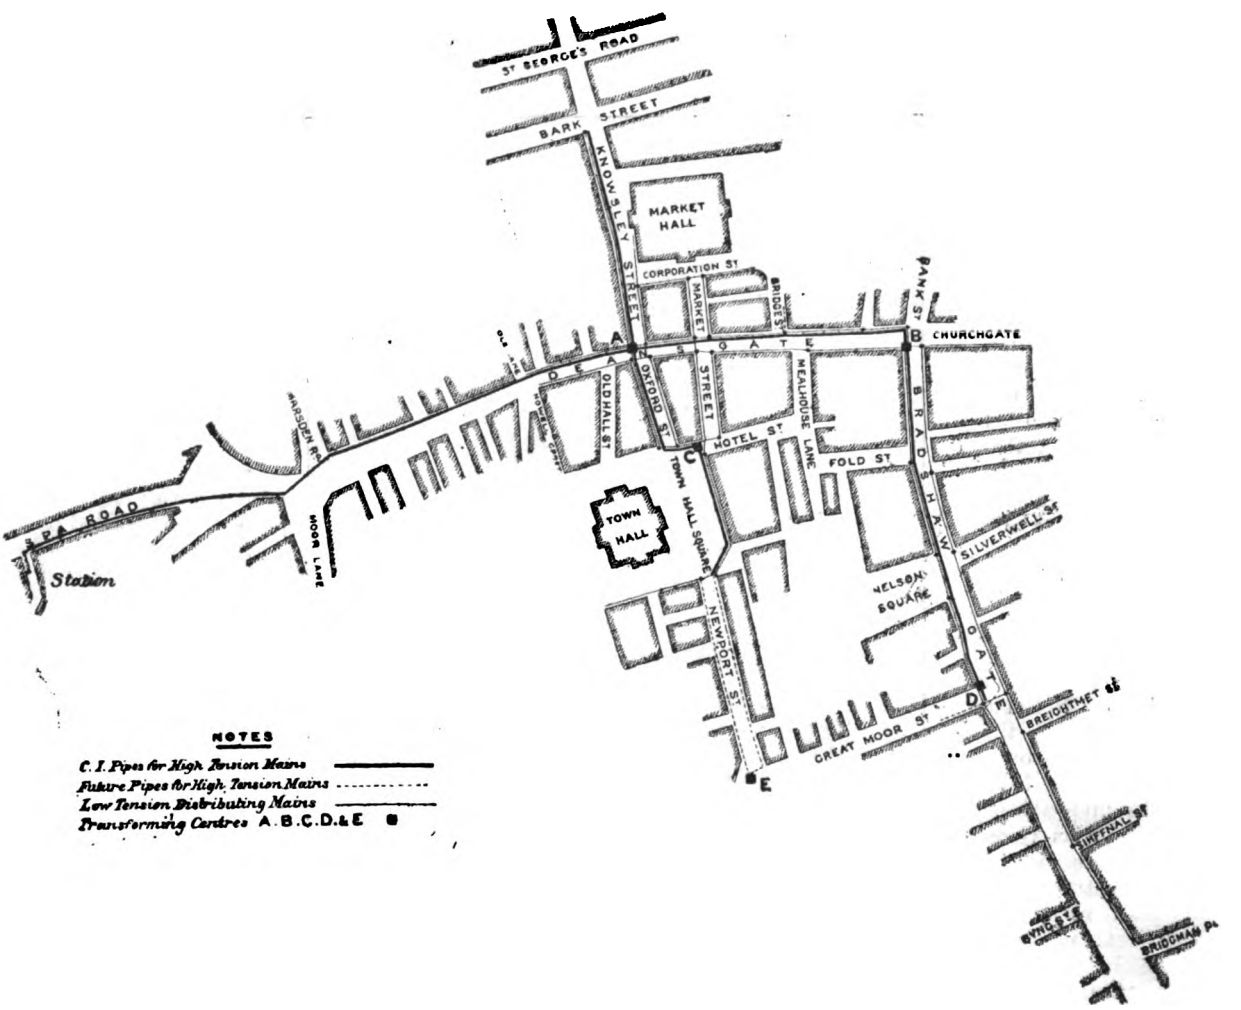
The sanction of the Local Government Board for the borrowing of £22,700 was given on October 6 of last year. This amount was allowed for the initial installation, leaving the Corporation to apply for further sanction when necessity arose. Messrs. Hinnell and Murphy, of Bolton, were appointed architects for the erection of the generating station buildings, and plans submitted by them having been approved of, tenders for the erection of the buildings were invited. Tenders were received both from firms within and outside the borough. As, however, the Corporation considered it desirable to entrust the work to ratepayers, and as the complete tenders received from those in the borough were not satisfactory, it was decided to obtain separate tenders for the various kinds of work. Finally, the work was let in the following contracts with Bolton tradesmen :

Excavating and concreting, Mr. G. S. Goodlad	£440	0	0
Bricklayer's work, Mr. Jas. Bradbury	2,058	5	0
Stonework, Messrs. Gregson and Smith	2,060	0	0
Carpentry and joinery work, Messrs. W. Burrow and Son	1,045	0	0
Slaters' work, Messrs. Warr and Co.	124	0	0
Plumbers' work, Messrs. Rd. Cuerden and Son	99	6	1
Painter and plasterer's work, Mr. Henry Critchley ..	96	0	0

It was contemplated, in accepting the above tenders, that the carrying out of some portion of the work as designed should be deferred, but it having since been determined to complete the buildings, an additional further outlay beyond the above sum has been incurred, amounting to about £1,000.

The contracts for the steam and electrical plant, according to the plans and specifications of Mr. J. H. Rider, were placed with the following firms :

Steam-engines and crane, Messrs. J. and E. Wood, Bolton	£2,113	10	0
Boilers, pipes, pumps, etc., Messrs. Hick, Hargreaves, and Co., Limited, Bolton	3,525	0	0
Alternators, dynamos, and transformers, Brush Electrical Engineering Company, Limited, London ...	2,808	5	6
High and low tension cables, Messrs. Siemens Bros. and Co., Limited, London	2,645	0	0
Switchboards, Manchester Edison-Swan Company, Limited, Manchester.....	930	0	0
Accumulators, Crompton-Howell Company, Limited, London.....	231	12	0
Cast-iron pipes, Staveley Iron Company, Limited ...	247	10	0
Transformer-chambers, Mr. W. Pollitt, Bolton	258	4	0



Bolton.—Map showing District Supplied.

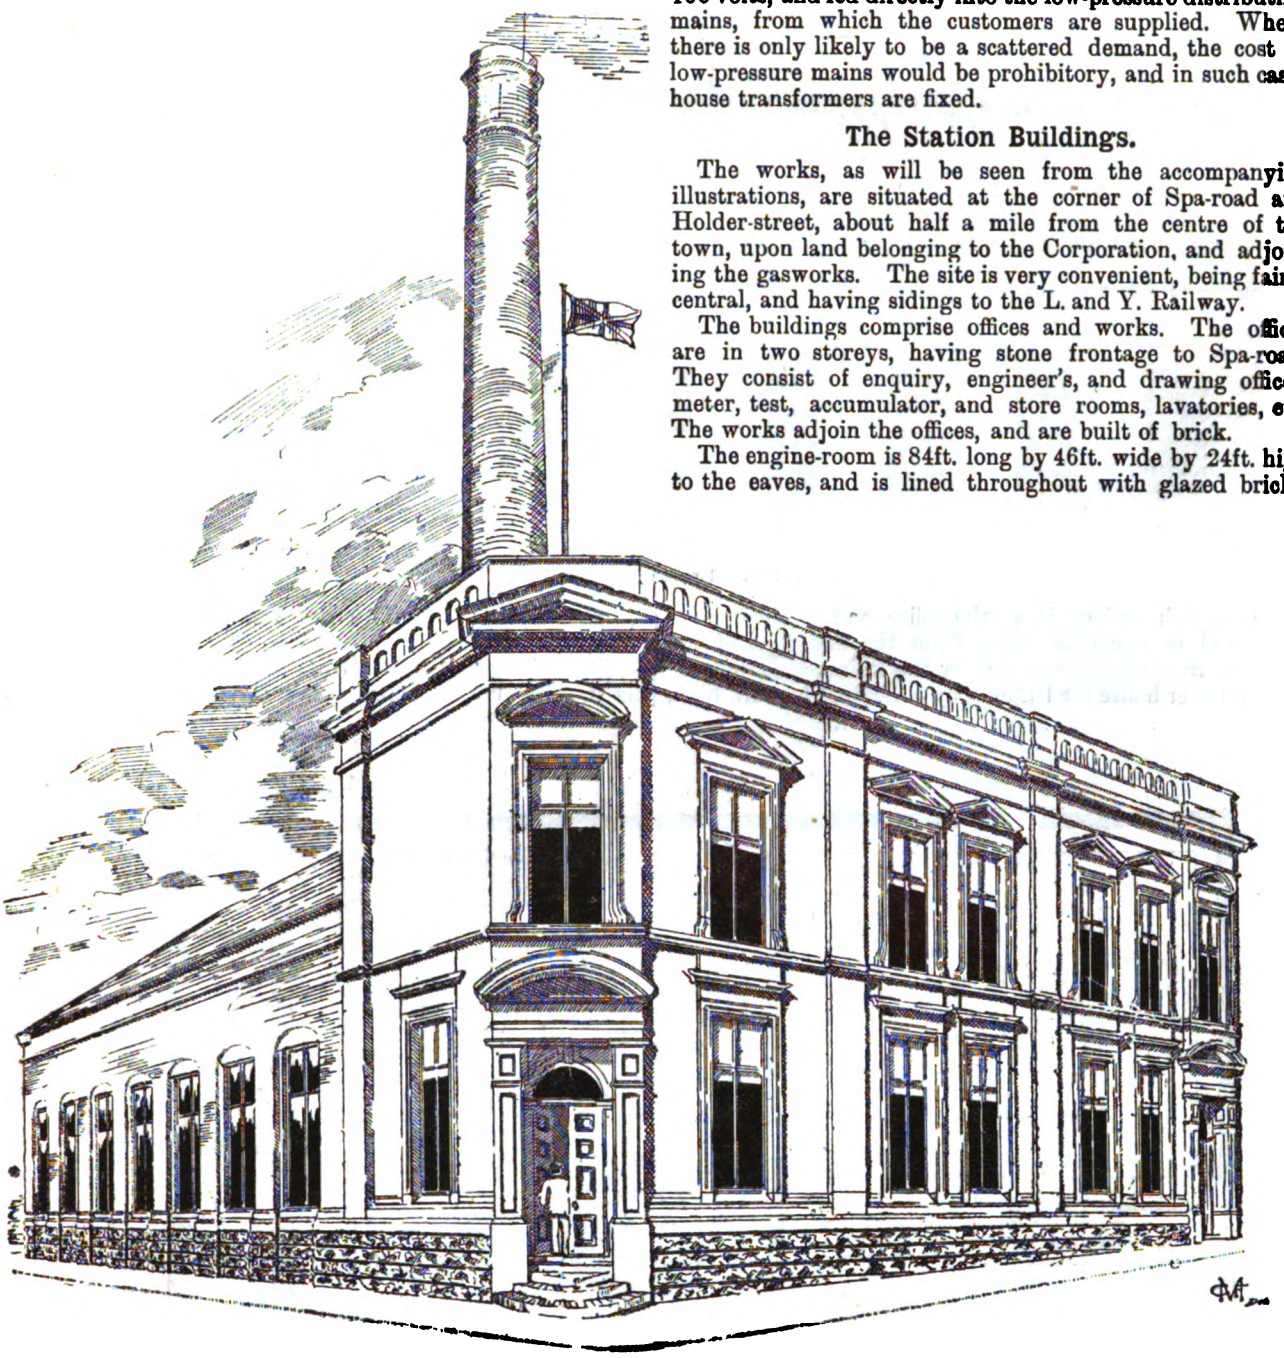
The work of erection was commenced under the general supervision of Mr. Rider, with Mr. D. Lee as clerk of works, and on December 13, 1893, the chairman of the committee (Mr. Alderman Miles, J.P.) laid the memorial-stone in commemoration of the commencement of the buildings the Mayor (Mr. Alderman Nicholson, J.P.) presenting to him for the purpose of the ceremony a silver trowel, the gift of the members of the committee, and the architects a mallet. During the progress of the work several enquiries came for electric light outside the compulsory area, and the committee therefore decided to extend the mains into Corporation-street, Newport-street, and Mawdsley-street. An additional transforming-chamber has also been provided at the junction of Newport-street with Great Moor-street.

The System Adopted.

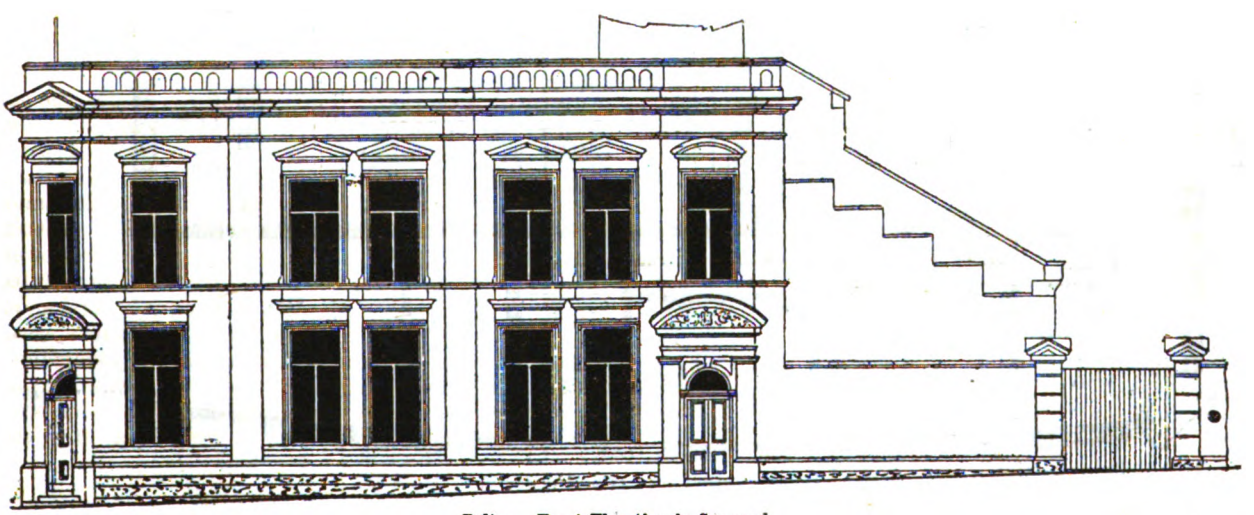
The scope and features of the undertaking as already carried out, and in prospect, are more fully detailed in the following particulars. The electricity works have been designed with a view to ultimately supply the whole of the borough, although at the present time mains are

Digitized by Google

only laid in the centre of the town, as indicated in the annexed map.



Bolton.—External View of Station Buildings.



Bolton.—Front Elevation in Spa-road.

The system adopted may be briefly described as follows: An alternating current of 2,000 volts pressure is generated at the works, and sent through separate feeder cables to transformer sub-stations. Here it is transformed down to 100 volts, and fed directly into the low-pressure distributing mains, from which the customers are supplied. Where there is only likely to be a scattered demand, the cost of low-pressure mains would be prohibitory, and in such cases house transformers are fixed.

The Station Buildings.

The works, as will be seen from the accompanying illustrations, are situated at the corner of Spa-road and Holder-street, about half a mile from the centre of the town, upon land belonging to the Corporation, and adjoining the gasworks. The site is very convenient, being fairly central, and having sidings to the L. and Y. Railway.

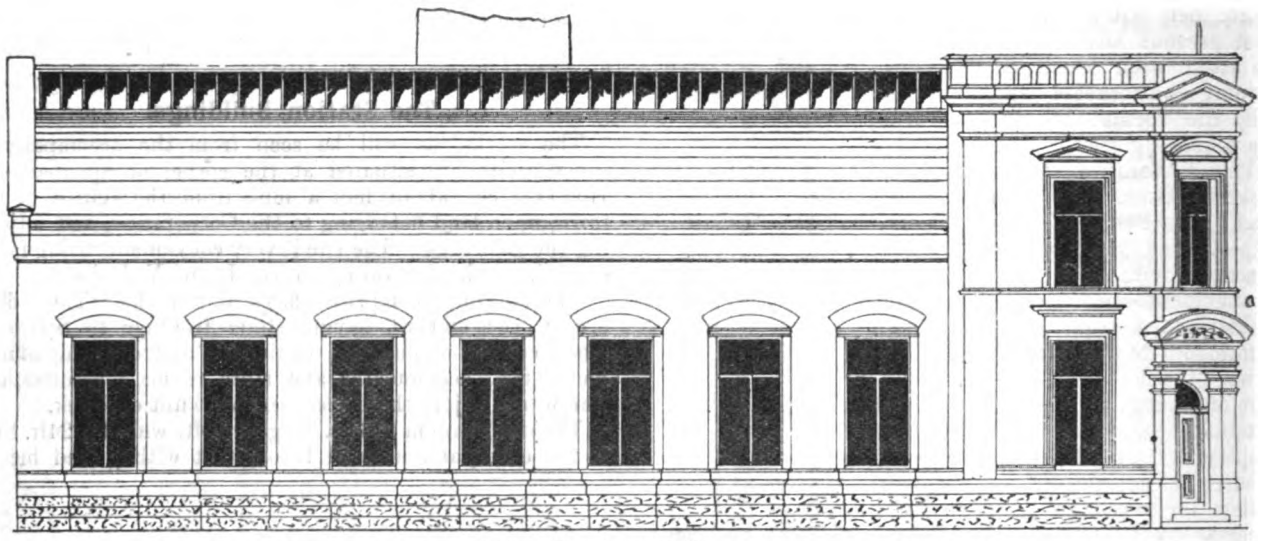
The buildings comprise offices and works. The offices are in two storeys, having stone frontage to Spa-road. They consist of enquiry, engineer's, and drawing offices, meter, test, accumulator, and store rooms, lavatories, etc. The works adjoin the offices, and are built of brick.

The engine-room is 84ft. long by 46ft. wide by 24ft. high to the eaves, and is lined throughout with glazed bricks. The roof is of varnished pitch-pine, and the floor is laid with wood blocks. It will be observed that ample room

Digitized by Google

is provided for any extensions of the machinery which may be required, whilst at the same time there is space available for further extensions of the buildings.

mounted by an ornamental cap of terra-cotta. Facing the boilers is a row of bunkers, into which the fuel is shot from the yard overhead.



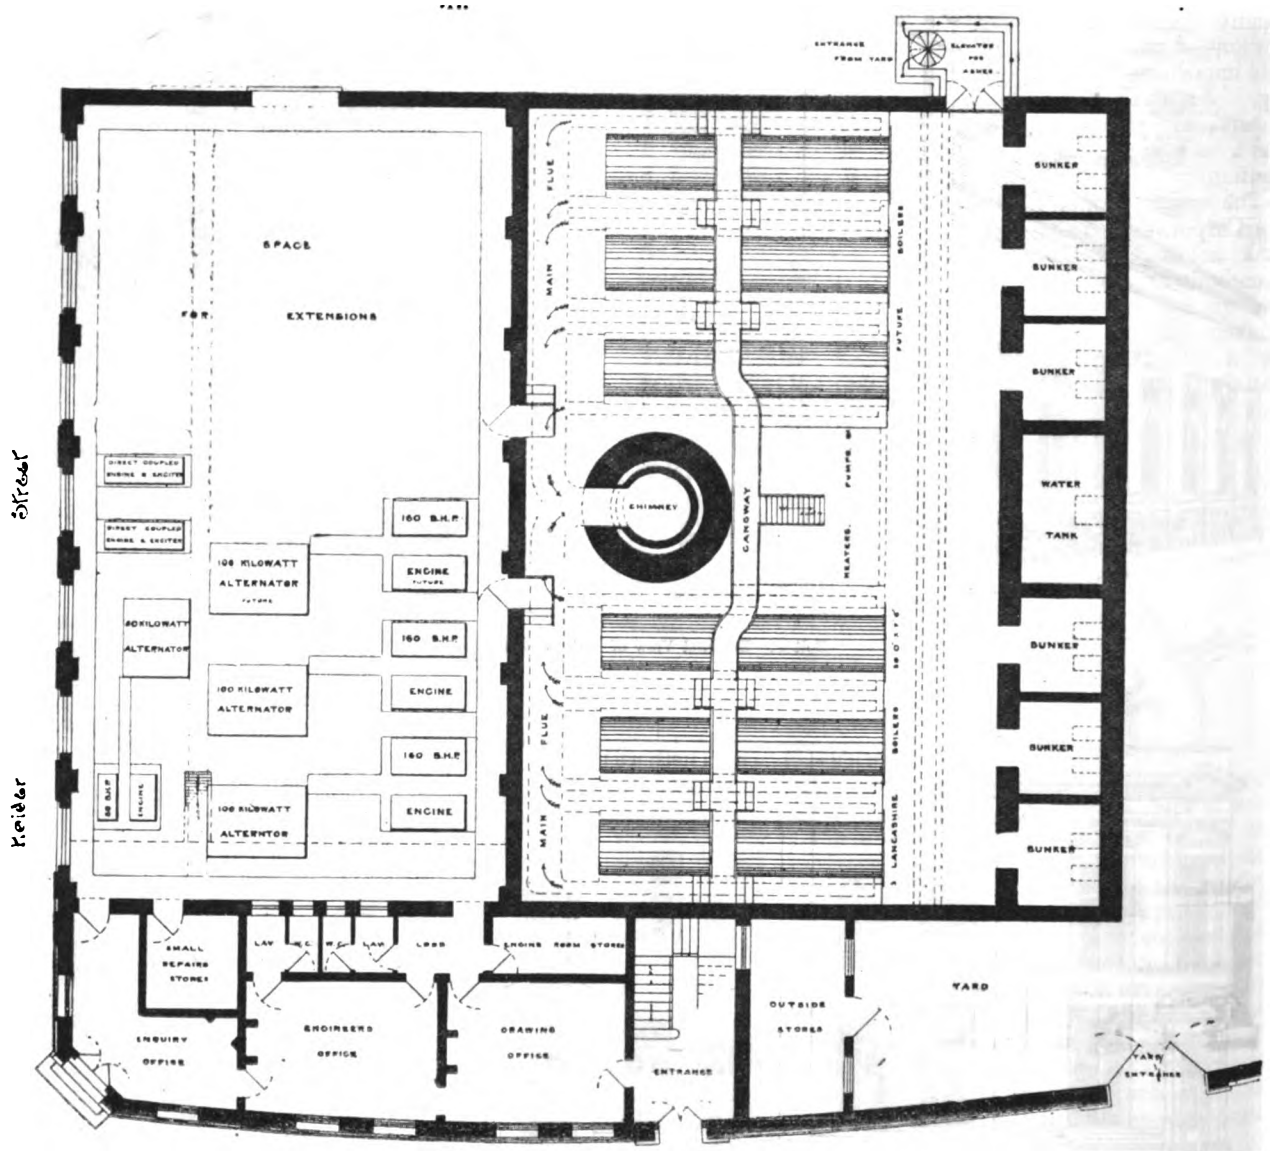
Bolton.—Elevation in Holder-street.

The switch gallery is at the office end of the engine-room, and is accessible either from the first floor of the offices or from the engine-room by the staircase, as shown.

The boiler-house is 84ft. long by 50ft. wide by 32ft. high,

The Boilers.

Three boilers, of the Lancashire type, are at present fixed, although accommodation is provided for another



Bolton.—Ground Floor Plan of Electricity Works.

and lies parallel with the engine-room, but some 6ft. below its level. The chimney is built within the boiler-house, there being space for three boilers on either side. The chimney is 158ft. high from flue bottom, and is sur-

battery of three boilers, as shown. The boilers have been made by Messrs. Hick, Hargreaves, and Co., Limited, of Bolton, and are 30ft. long by 7ft. 6in. diameter. Each boiler has two internal flues, 3ft. diameter,

Digitized by Google

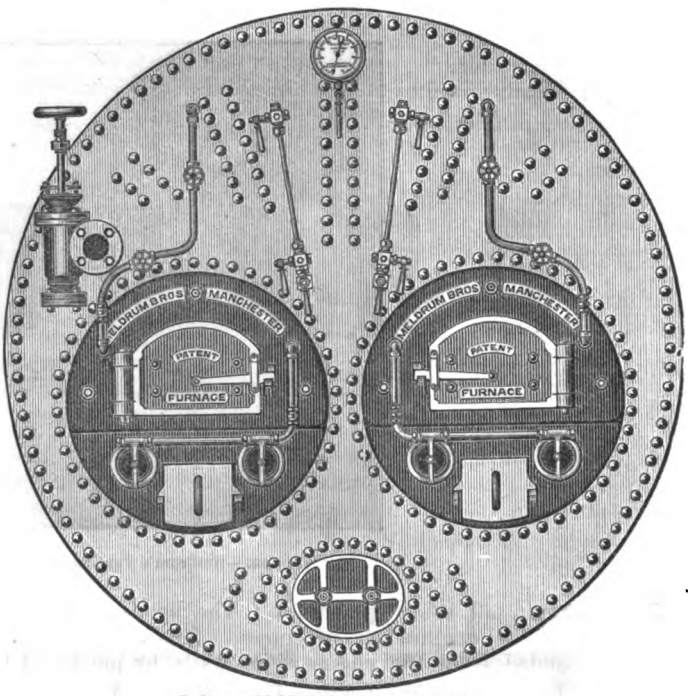
with five Galloway tubes in each. The boiler mountings throughout are by Messrs. Hopkinson, of Huddersfield. The boilers are of steel, and are made for a working pressure of 120lb. per square inch. Hand firing is at present adopted, and the furnaces are fitted with Meldrum's furnace for burning coke breeze, and other waste fuel, the former being obtained from the adjoining gasworks.

This system, which is due to Messrs. Meldrum Bros., of Atlantic Works, City-road, Manchester, is based upon the employment of forced draught in con junction with firing by hand. The arrangement not only allows of the utilisation of cheap fuels of the kinds mentioned, but it also permits of the power of the boilers being increased in case of emergency to much beyond that obtainable where natural draught is employed. This fact, the makers show, renders it possible to put down fewer boilers for meeting the maximum load, whereas additional boiler power is required to cope with this particular load where this method has not been introduced. Another feature of this kind of furnace is that in the emergency of a fog or other sudden demand for steam, the furnaces are capable of rapidly increasing the rate of combustion—a matter which is of considerable importance in central-station working. Annexed are illustrations of Messrs. Meldrum's Lancashire boilers and a back view showing the blowers in position.

The water supply is obtained from the Corporation mains, and a storage tank holding about 5,000 gallons has been built in the position indicated on the ground floor plan between the bunkers. From this the water is drawn by a Worthington vertical marine-pattern pump, provided by the Worthington Pumping Engine Company, of Queen Victoria-street, E.C., and fed into the boilers through a Berryman exhaust steam heater. The arrangements for feeding the water, as shown on the elevation of the boilers, have been duplicated throughout.

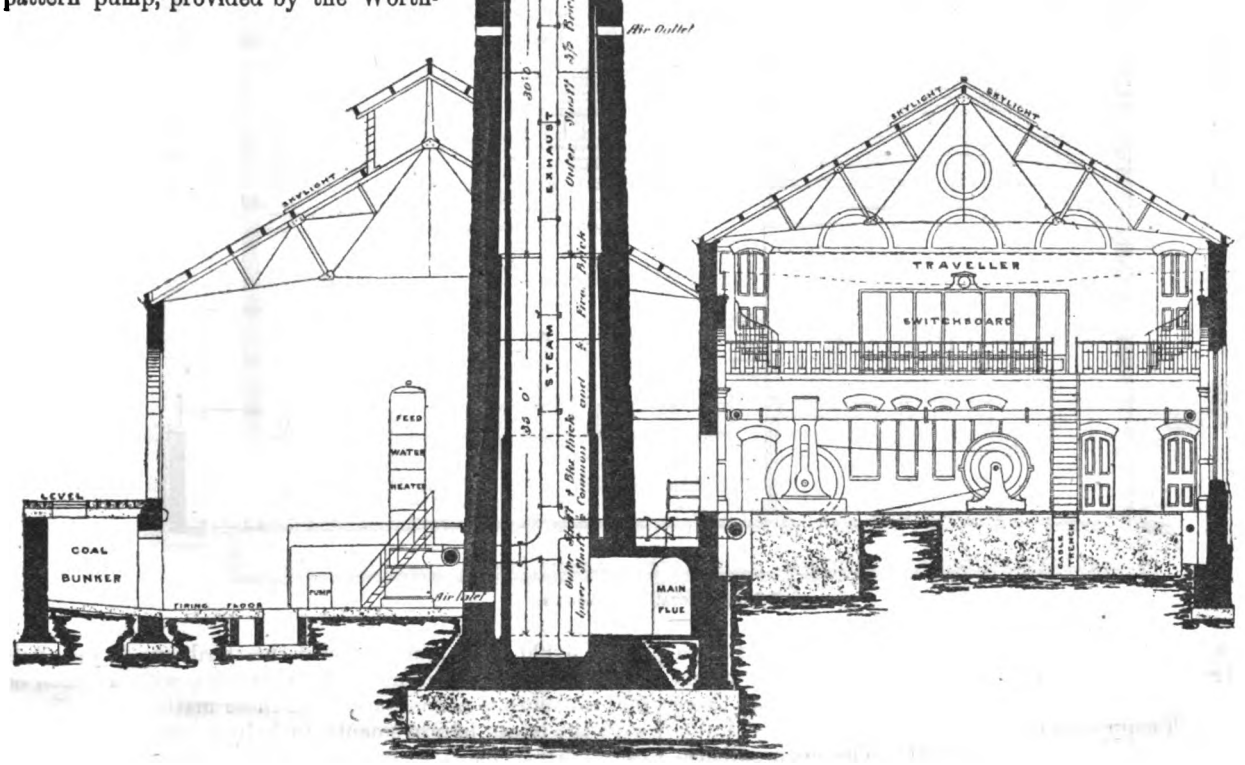
The Steam-Engines.

The main engines are three in number, by Messrs. J. and E. Wood, of Bolton. They are of the compound vertical type, having the novel feature, at least for central-station work, of grooved flywheels between the cylinders.



Bolton.—Meldrum's Lancashire Boiler.

The two larger engines are for 160 b.h.p., having cylinders 13in. and 21in. diameter and 15in. stroke, and run at 180 revolutions per minute. The smaller engine is for 80 b.h.p., having cylinders 10in. and 15in. diameter and 12in. stroke, and runs at 220 revolutions per minute.



Bolton.—Cross-section through Boiler-house and Engine-room

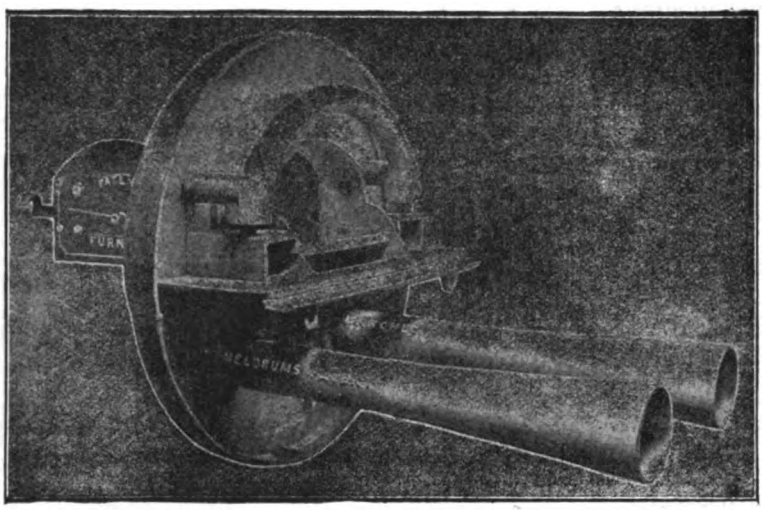
Both high and low pressure cylinders are fitted with expansion valves, those on the high-pressure cylinders being controlled directly by the governors. The governors

Digitized by Google

are driven by wheel gearing, and are adjustable while running. In addition to these engines, there are two small vertical engines of 15 b.h.p., by Messrs. Robey and Co., Limited, of Lincoln, these being coupled direct to the exciters.

The steam-pipes, as shown in the general arrangement of steam mains, are in the form of a ring main, and are of wrought iron with wrought-iron flanges. The main ring is 9in. diameter, and the supply pipes from the boilers are heaters, as desired. This arrangement will be evident from the plan of steam and feed pipes. The whole of the pipe work, including pumps and heater, has been supplied and erected by Messrs. Hick, Hargreaves, and Co., Limited.

We must not omit to mention that the engine-room is equipped with an overhead traveller, having a span of 46ft., and supplied by Messrs. J. and E. Wood, of Bolton the makers of the engines. The traveller is worked by hand, and arranged for both slow and fast speeds.

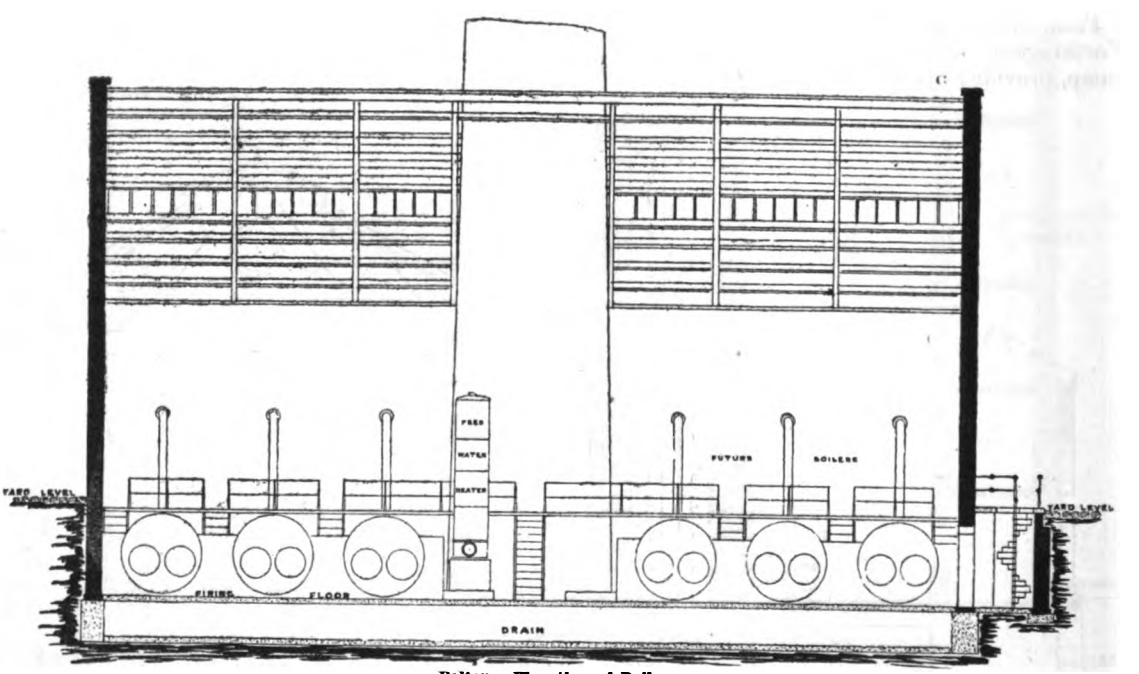


Bolton.—Meldrum's Furnace. Back View, Showing Blowers in Position

7in. diameter, all being $\frac{3}{8}$in. thick. The bends and the branches to the engines are of copper. The steam-pipes are suspended from the engine-room walls by means of brackets and rods, so as to allow freedom for expansion. McDougall separators are fixed in each branch, and by means of Hopkinson's parallel slide valves any section of the main ring may be cut out. The pipes are drained through a McDougall steam-trap into the water-tank. Hopkinson's back-pressure or "isolating" valves are fixed in the branches from the boilers.

The Alternators and Exciters.

At present only three alternators are installed, but in the ground floor plan a fourth machine and engine are shown. These will, of course, be put in as occasion arises. The three alternators are of the Mordey Victoria type supplied by the Brush Electrical Engineering Company, Limited. Two of these machines are of the 100-kilowatt size, capable of giving 50 amperes at 2,000 volts, with a speed of 430 revolutions per minute, sufficient to light



Bolton.—Elevation of Boilers.

The exhaust-pipes are of cast iron, and vary in size from 4in. to 18in. diameter. They are laid in a trench round the engine-room. The engines exhaust directly into these pipes through copper bends and cut-off valves. The drains from the engines are also connected. The main exhaust-pipe is 18in. diameter, and is carried, as will be observed from the cross-section of boiler and engine house, to a height of about 85ft. inside the chimney. It is supported by means of collars and radial rods. The exhaust steam may be led directly into the chimney or round by the feed-water

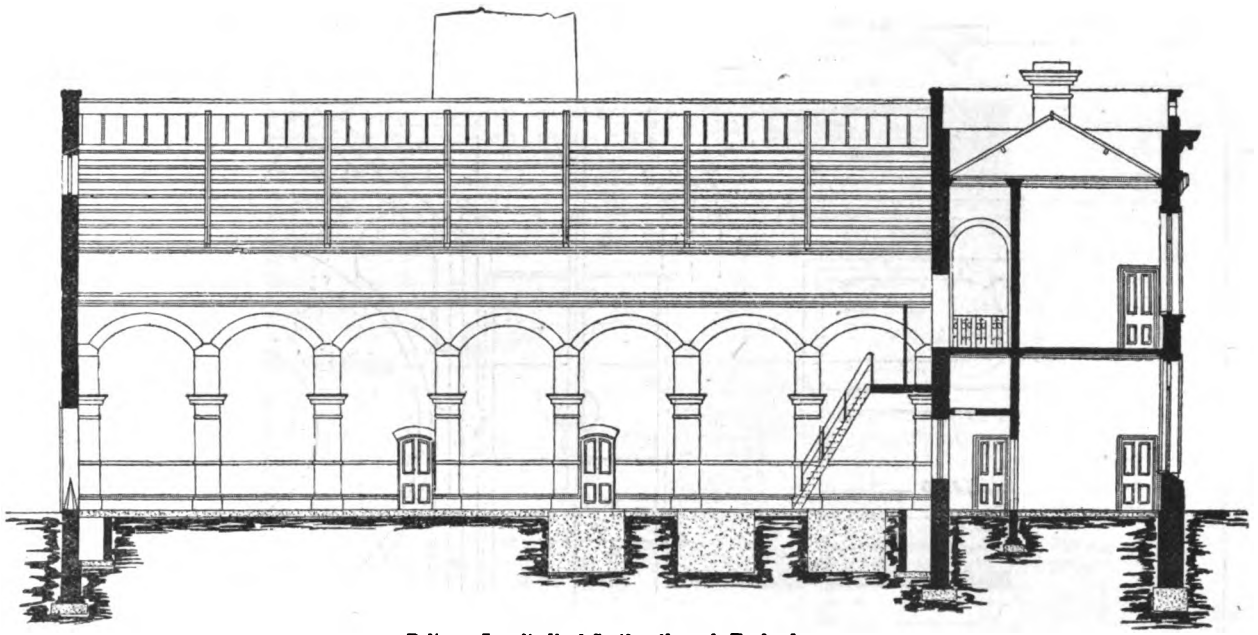
about 3,500 8-c.p. lamps; whilst the third one is just half the size, giving 25 amperes at 2,000 volts, with a speed of 600 revolutions per minute. All these machines are fitted with the latest improvements, including continuous lubricating arrangements, and are driven from the engine flywheels by cotton ropes, the larger ones by 10 of $1\frac{1}{4}$in. diameter, and the smaller one by eight of 1in. diameter. The alternators are mounted on strong slide rails, fitted with tightening screws and ratchet levers, so that the ropes may be readily tightened whilst running. The armatures

Digitized by Google

are so arranged that any defective coil can be replaced in a few minutes, each coil, in fact, being independently held, and the machines work perfectly in parallel at any load.

with the Brush Company's improved brush-holders, and with automatic lubrication in the form of chains running in baths of oil formed in the pedestals of the bearings.

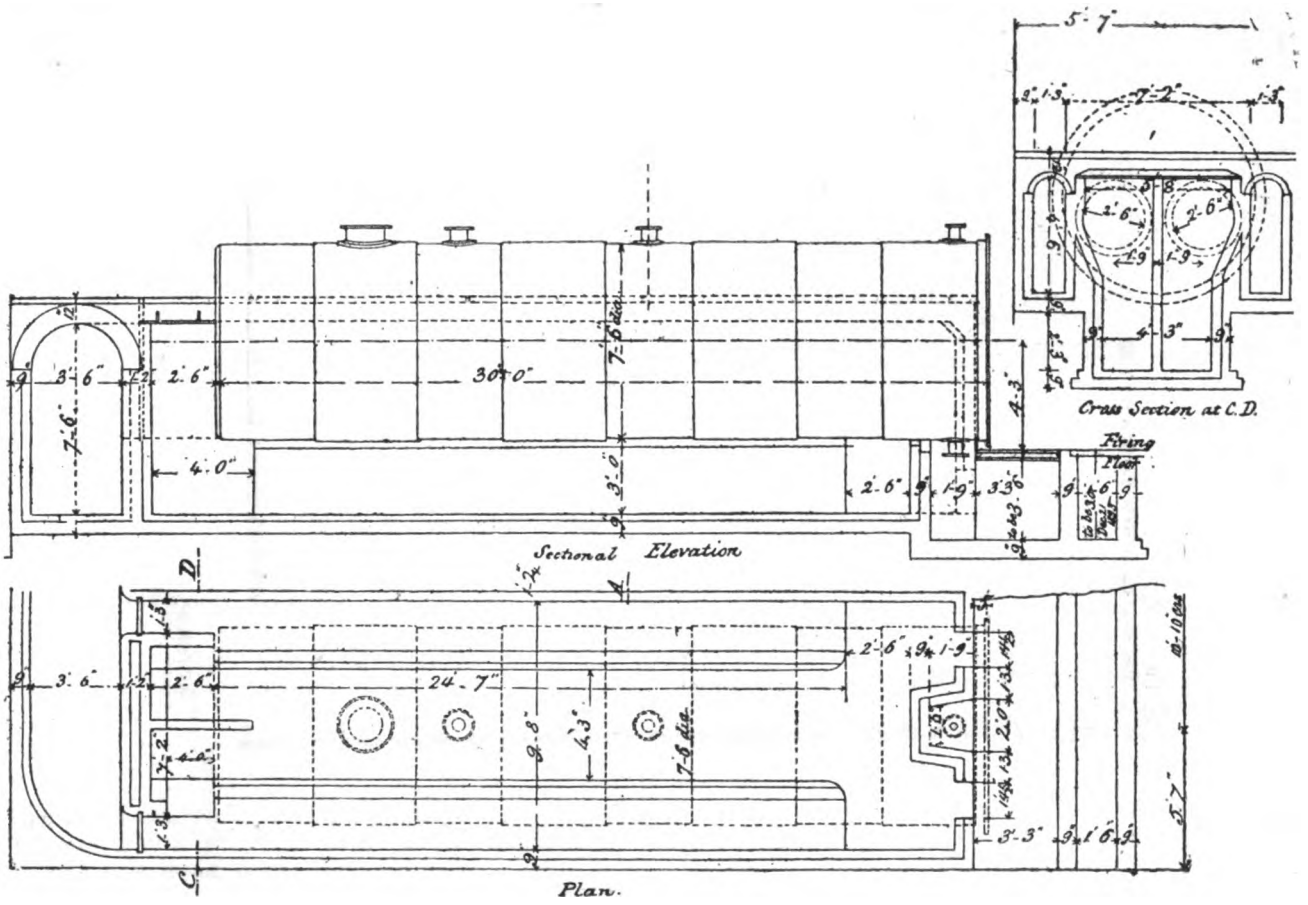
In addition to the exciters, a set of 55 Crompton-Howell



Bolton.—Longitudinal Section through Engine-house

The excitation of the alternators is effected by two Brush-Falcon two-pole dynamos, also supplied by the Brush Company. Each exciter is mounted on a combined bedplate with, as already mentioned, a Robey engine, and designed to run at 270 revolutions per minute. Each exciter is capable of giving 90 amperes

accumulators, supplied by the Crompton-Howell Electrical Storage Company, Limited, of Mansion House-buildings, London, E.C., has been erected. These are of 360 ampere-hour capacity, and may be discharged at any rate up to 130 amperes. The cells are intended for exciting during times of light load, and also to act as a "stand-by." They



Bolton.—Plan, Section, and Elevation of Boiler

at 100 volts, or 70 amperes at 130 volts—in the latter case for charging cells. This output is considerably more than sufficient for the excitation of the whole of the alternators at present installed. These machines have drum armatures, and the fields are shunt wound, being provided with large regulating resistances. They are fitted

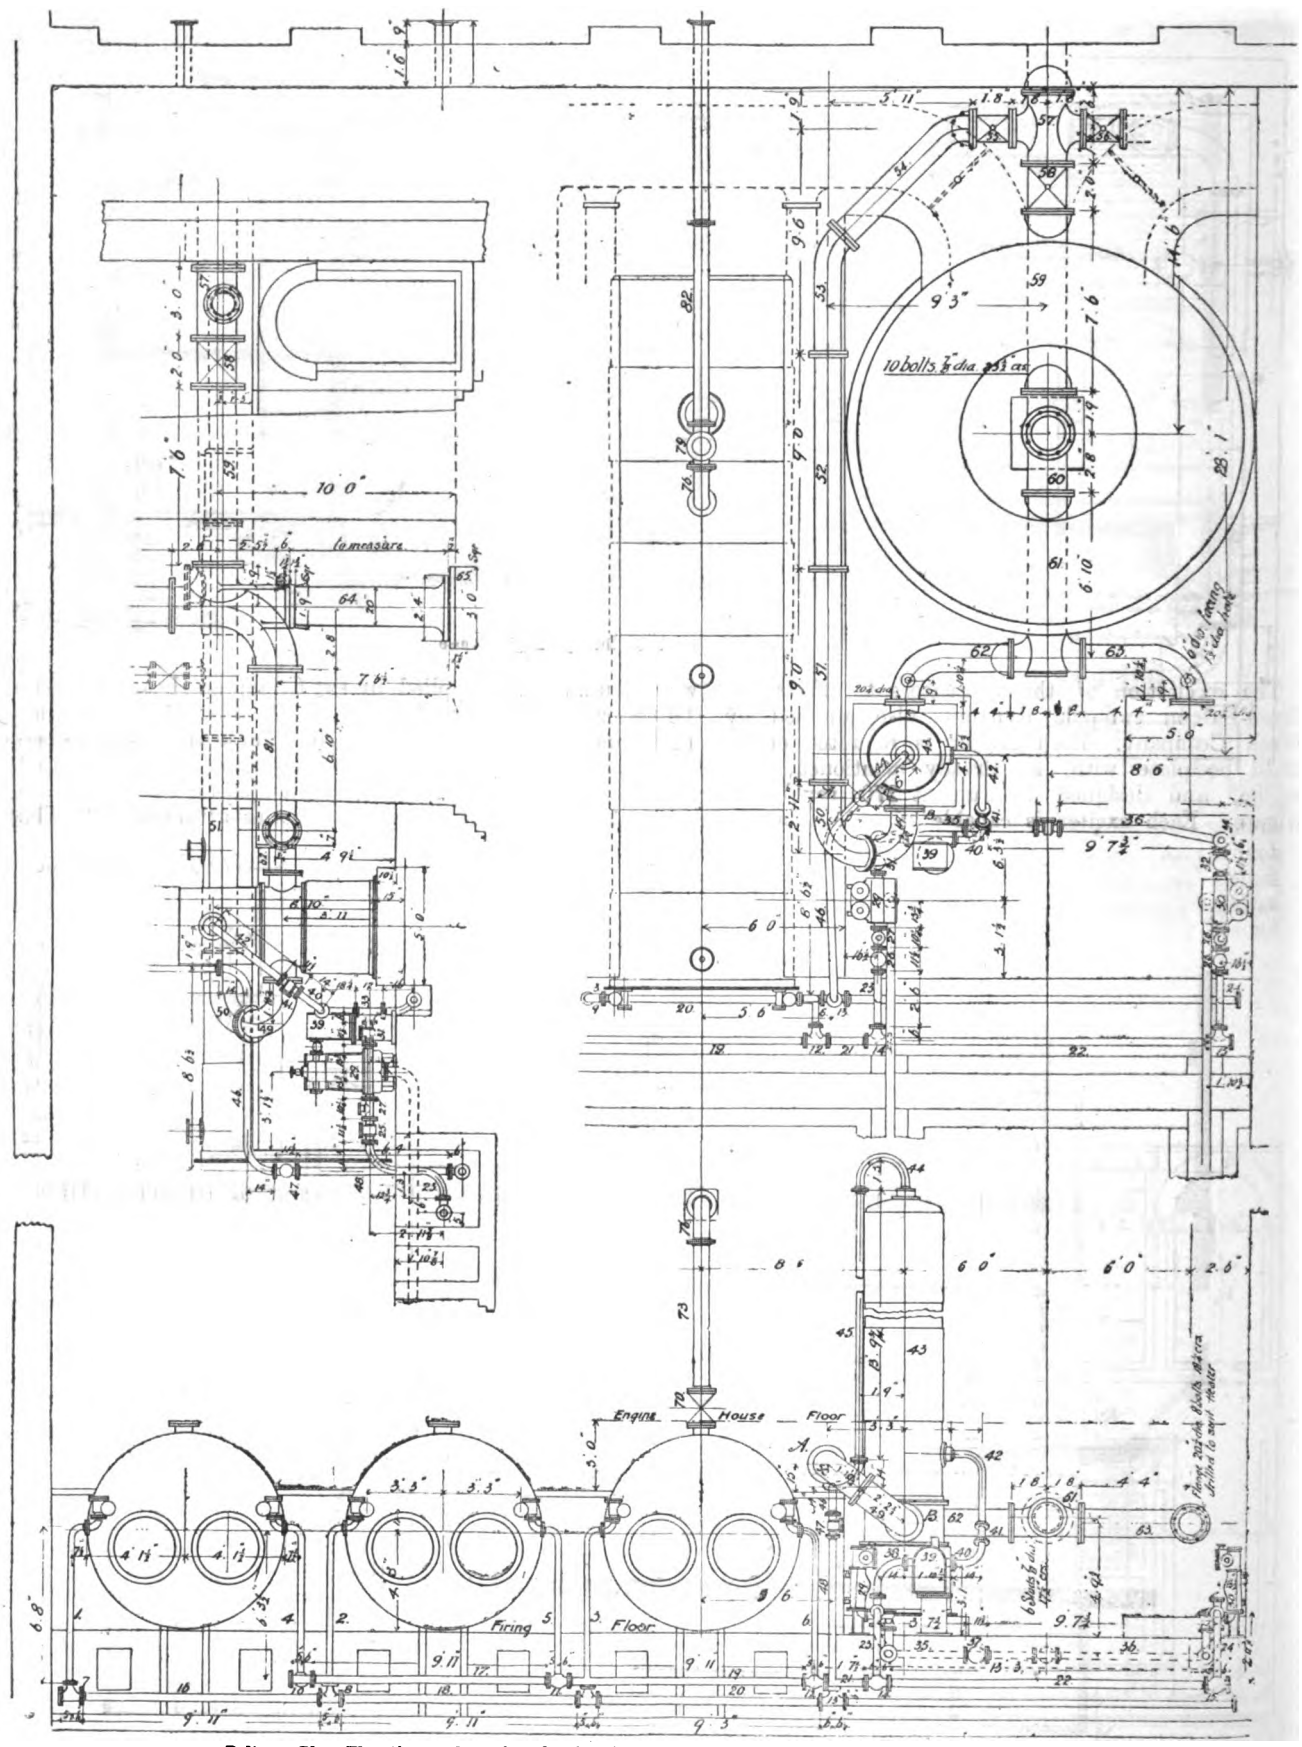
are charged from the exciting omnibus bars by raising the pressure of the exciters when required.

The Switchboard Arrangements.

The mains from the various machines are run in a passage under the engine-room floor to the switchboard.

Digitized by Google

This arrangement, which is illustrated in the cross-section of the engine-house, is very convenient, all the mains being readily accessible at any time. The switchboards, as will be seen from the plan of the first floor, is erected upon a switch gallery, and has been constructed by the Manchester Edison-Swan Company, Limited.



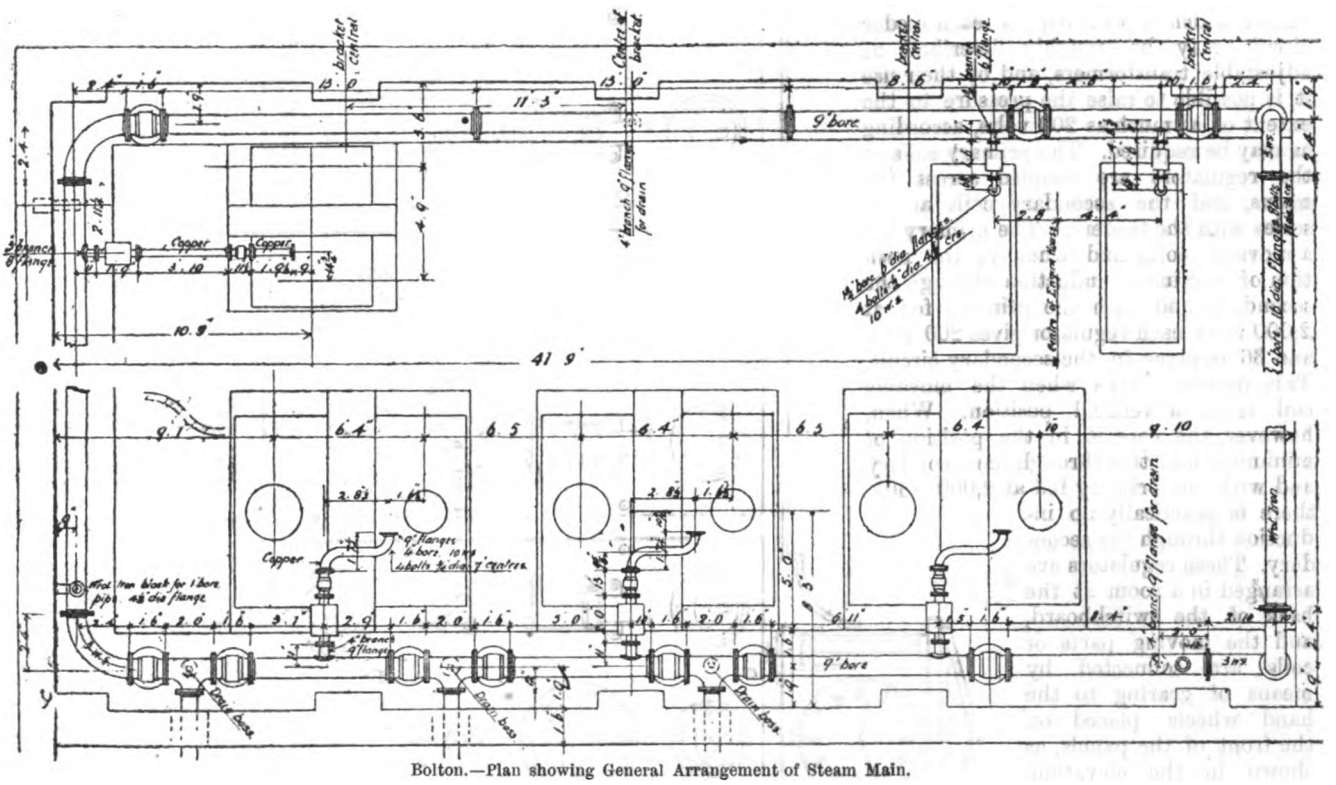
Bolton.—Plan, Elevation, and Section showing Arrangement of Steam and Feed Pipes in Boiler-house.

The general arrangement of the switchboard is represented in the subjoined elevation of the board, whilst the connections are shown diagrammatically. There are six enamelled slate panels, and apparatus is provided for four feeder circuits, two exciters, and one set of accumulators, four alternators, and for synchronising, the board being arranged for extension in either direction. The exciter panel, shown in the centre of the board, carries, for the two exciting dynamos and set of accumulators, two ammeters, two voltmeters, one alternating-current voltmeter, and two double-pole exciter field switches. The two feeder panels, which are shown on the right, contain, for the four feeder circuits, four alternating-current ammeters, four alternating-current voltmeters, four double-pole fault

Digitized by Google

detectors, four feeder regulators, four double-pole feeder switches and fuses.

The two alternator panels for the four alternators are equipped with four alternating ammeters, four direct-current meters, four double-pole alternator field switches, four

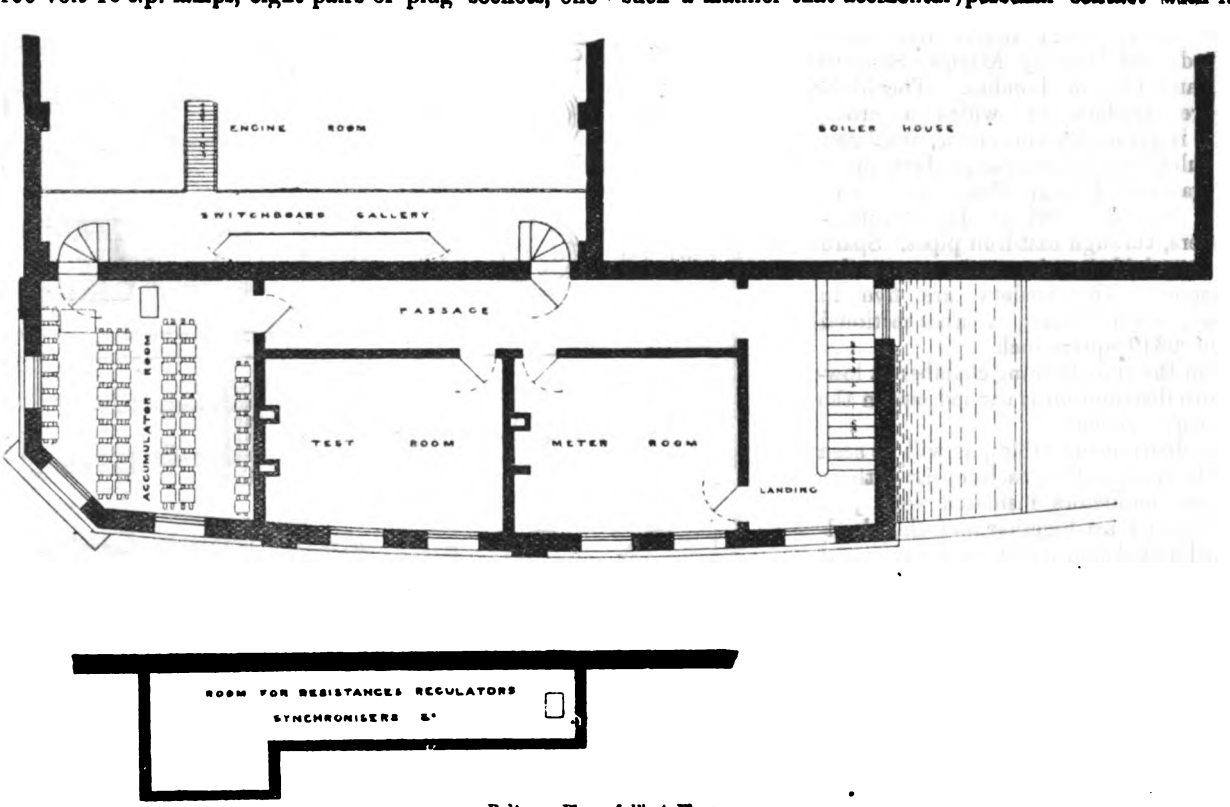


Bolton.—Plan showing General Arrangement of Steam Main.

circular resistance switches for the alternator fields, four double-pole alternator switches, and fuses. To the left is shown the synchronising panel, which carries three alternating-current voltmeters, two bayonet-jointed lamp sockets for 100 volt 16-c.p. lamps, eight pairs of plug sockets, one

meters in the testroom on their way to the switchboard. Pilot wires are run back from the transforming centres and connect to voltmeters on the switchboard, so that the attendant has an actual control over the pressure in any part of the system. The regulation of the station pressure as a whole is done by means of adjustable resistances in the exciter field.

A noteworthy feature of the switchboard is the fact that all apparatus carrying high-pressure current is protected in such a manner that accidental personal contact with it is



Bolton.—Plan of First Floor.

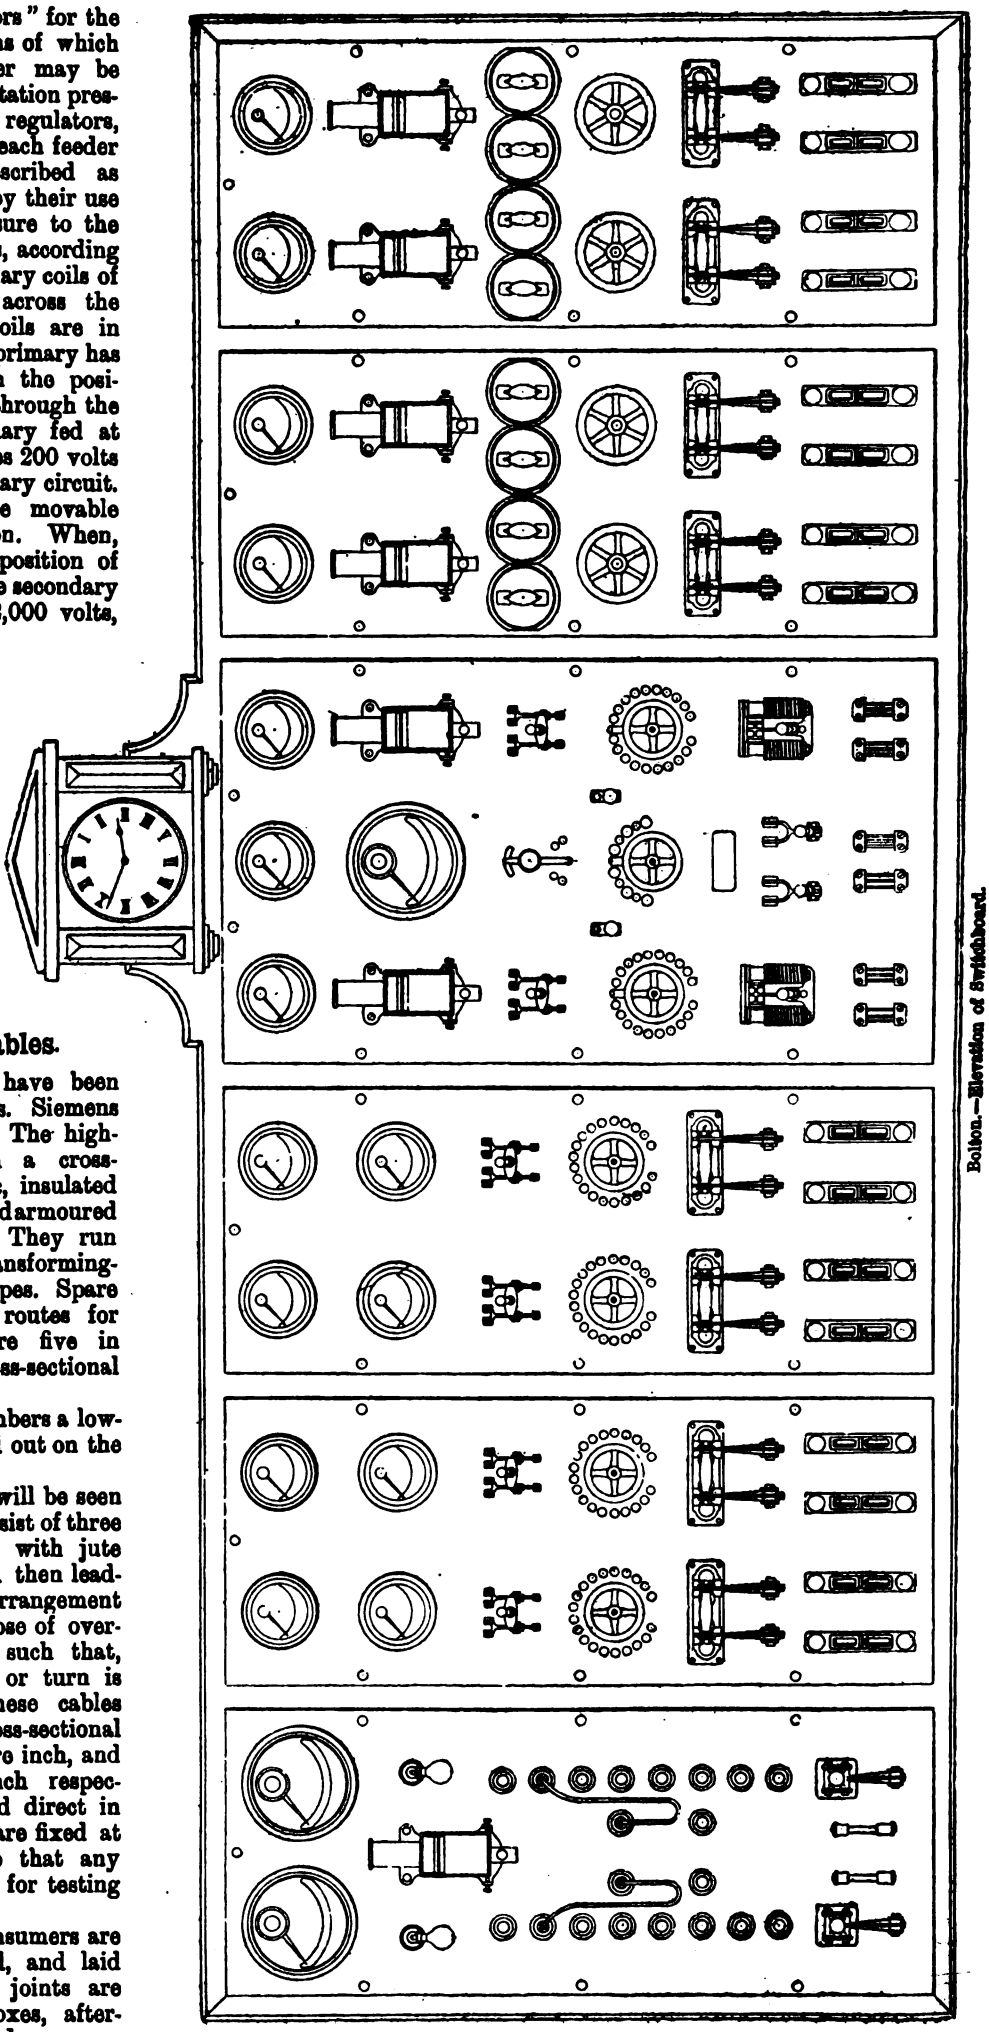
pair of plug cords with plugs, two synchronisers, and two double-pole synchroniser switches. The ammeters are of the Nalder pattern, and the voltmeters are of the electrostatic type by Mr. White for low pressures, and by Messrs. Elliott Bros. for high voltages. The mains from the alternators are connected to Thomson-Houston registering watt-

impossible. For instance, when it is desired to close a circuit the switch is thrown back to the panel, the connection being formed in what may be termed a recessed slot or wedge arrangement in the panel. Similar recesses are provided for the fuse contacts.

An ingenious arrangement has been devised by Mr

Digitized by Google

Rider in the way of "regulators" for the feeder circuits, and by means of which the pressure of either feeder may be independently regulated, the station pressure being unaltered. These regulators, one of which is provided for each feeder circuit, may be roughly described as adjustable transformers, and by their use it is possible to raise the pressure to the extent of as much as 200 volts, according as may be required. The primary coils of the regulators are coupled across the mains, and the secondary coils are in series with the feeders. The primary has a movable core, and when in the position of maximum induction through the secondary and with the primary fed at 2,000 volts, each regulator gives 200 volts and 36 amperes in the secondary circuit. This position exists when the movable coil is in a vertical position. When, however, the core is in the position of minimum induction through the secondary and with the primary fed at 2,000 volts, there is practically no induction through the secondary. These regulators are arranged in a room at the back of the switchboard, and the moving parts or coils are connected by means of gearing to the hand wheels placed on the front of the panels, as shown in the elevation. Each regulator is provided with double-pole high-pressure fuses in the primary circuit.



Bolton.—Elevation of Switchboard.

The Underground Cables.

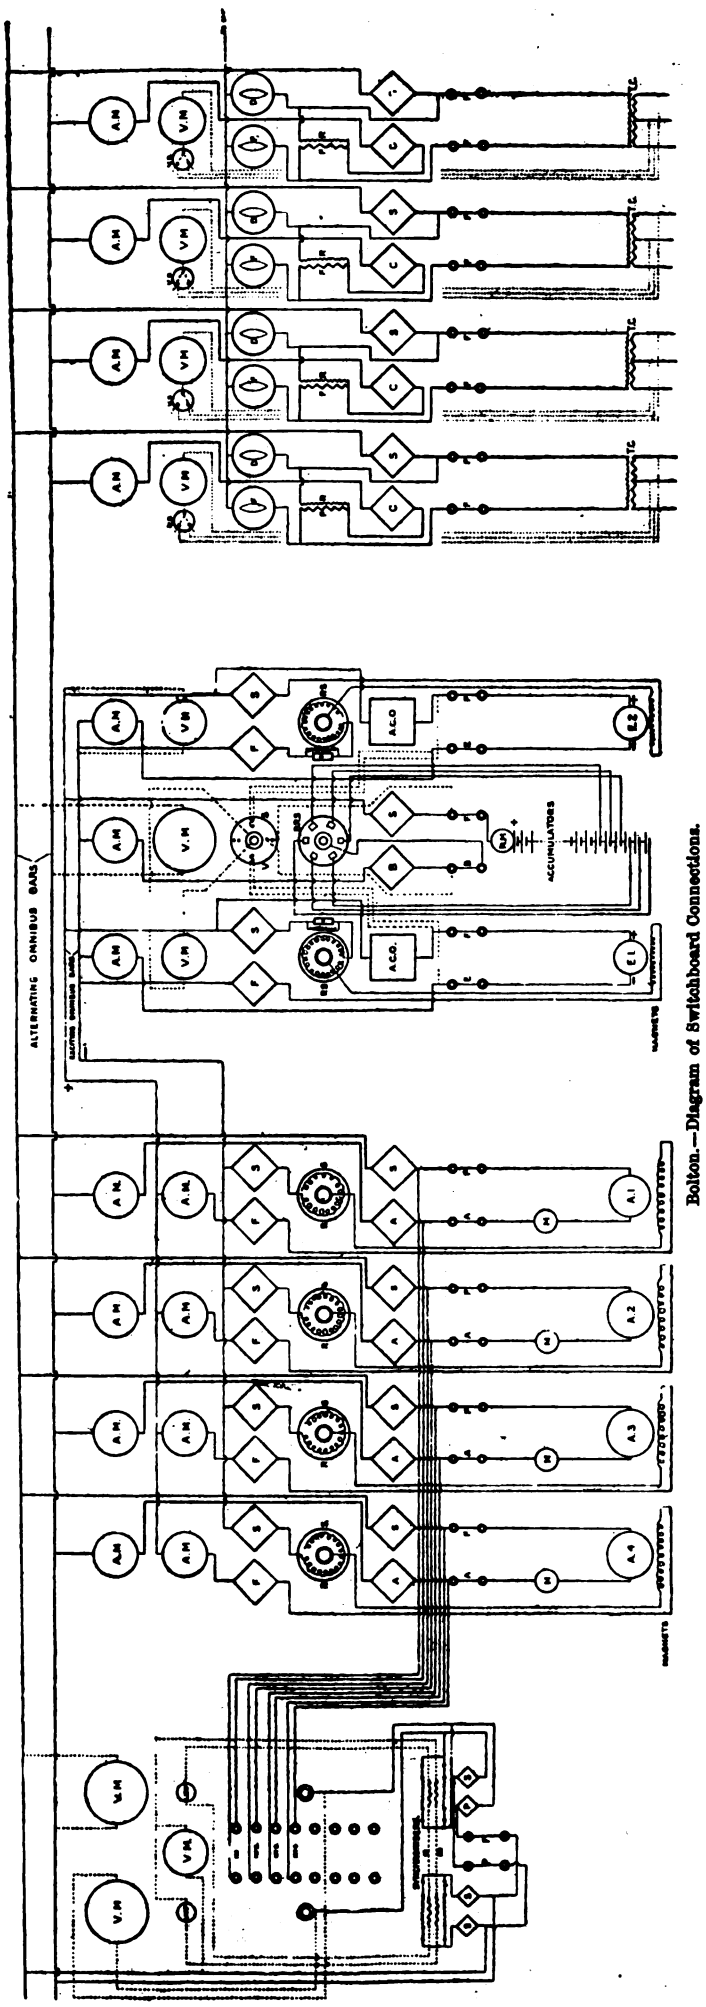
The underground mains have been supplied and laid by Messrs. Siemens Bros. and Co., of London. The high-pressure feeders, of which a cross-section is given, are concentric, insulated with vulcanised indiarubber, and armoured with galvanised steel wires. They run direct to the various transforming-chambers, through cast-iron pipes. Spare pipes are laid in the main routes for extensions. The feeders are five in number, each having a cross-sectional area of ·0349 square inch.

From the transforming-chambers a low-pressure distribution is carried out on the three-wire system.

The distributing cables, as will be seen from the cross-section, each consist of three separate conductors, insulated with jute fibre, twisted up together and then lead-covered and armoured. This arrangement of each strand for the purpose of overcoming inductive effects is such that, practically, a complete twist or turn is made about every 12in. These cables are of two sizes, having cross-sectional areas of ·125, ·0625, ·125 square inch, and ·0625, ·035, ·0625 square inch respectively. These cables are laid direct in the ground. Junction-boxes are fixed at the points of intersection, so that any length may be readily isolated for testing or repairs.

The service wires to the consumers are twin rubber cables, armoured, and laid direct in the ground. The joints are made in special cast-iron boxes, afterwards filled up with compound.

Digitized by Google



Bolton.—Diagram of Switchboard Connections.

Transformer-Chambers.

The transforming-chambers are built of brick, and are placed in convenient centres under the footpaths, as shown on the map of district supplied. Five chambers are at present constructed, each being 6ft. square and 6ft. high inside. The walls are lined with white glazed brick, and access is gained by means of a double pavement cover. Each chamber will eventually contain five 18-kilowatt transformers, but not more than two are at present fixed in each. High and low pressure switches are provided for each transformer, and the various distributing mains connect through fuses to omnibus bars.

Eight transformers are at present placed in the various chambers. These are by the Brush Electrical Engineering Company, Limited, and are of the 18-kilowatt size, as shown in the illustration. The primaries are for 2,000 volts, and the secondaries for 200 volts, with a middle connection for the three-wire system. The transformers, which have earthed shields between the primary and secondary winding, are fixed in cast-iron cases, which also contain double-pole high-pressure switches and fuses. The low-pressure wires are carried to special switch and fuse boards, where they connect to the distributing network. The arrangement of the low-pressure switchboard is represented in the annexed illustration.

Private Lighting.

Distributing mains have been laid in the following streets—viz., Knowsley-street, Deansgate, Churchgate, Bradshawgate, Oxford-street, Market-street, Town Hall-square, Corporation-street, and Newport-street. Up to the present there have been 35 applications for current in these streets, with a demand equivalent to 3,500 lamps of 8 c.p. Several enquiries have also been received from persons in the main thoroughfares of the town outside the above streets, and immediately a sufficient demand arises mains will be forthwith laid, and additional plant put down to meet it.

Public Lighting.

As far as public lighting is concerned, nothing beyond the erection of an arc lamp in front of the Town Hall in Town Hall-square has been done. This is much to be regretted, for the characteristics of Bolton streets are such as to render advisable the introduction of a better system of lighting than that which at present obtains. Let the Gas and Electric Lighting Committee consider the matter, and bring up some recommendation on the subject before the Town Council. Surely, having sufficient confidence to establish electricity works, as indeed many other towns have done and are doing, Bolton will not be behind. the latter in lighting the main thoroughfares by means of arc lamps. Bolton sadly needs arc lamps, and, owning the gasworks, the Corporation should have no difficulty in deciding to replace gas by electricity. This transformation would brighten the central streets, assist the work of the police, remove the dulness from the town, and rejoice the hearts of the inhabitants.

As already stated, the electricity works of the Bolton Corporation have been designed by Mr. J. H. Rider, M.I.E.E., to whom we are much indebted for the information contained in the foregoing description. The execution of the work has been carried out under his superintendence, Messrs. Hinnell and Murphy have been the architects for the buildings, and Mr. D. Lee has been clerk of works. The undertaking has been under the direction of the Gas and Electric Lighting Committee of the Corporation, the members of which are:

ALDERMAN W. NICHOLSON, J.P., Mayor.
ALDERMAN JOHN MILES, J.P., Chairman.
ALDERMAN WM. BROUGHTON, Vice-Chairman.

COUNCILLORS:

W. BLEAKLEY.	J. HORROCKS.
W. COOPER, J.P.	E. KEARSLEY.
W. EDGE.	J. SHERRY, J.P.
J. FINNEY.	A. H. TAYLOR.
J. HOLT.	R. TOOTILL.
R. HORRIDGE.	

Mr. R. G. Hinnell is the town clerk, and at the request of the committee Mr. Alderman John Miles, J.P. (the chairman), started the supply of current last Wednesday.

MORE ELECTRIC TRACTION.

It is just about two years since the first steps were taken by the joint enterprise of the London Chamber of Commerce, the Tramways Institute, the Institution of Electrical Engineers, and other interests involved in the matter to obtain a full discussion by the proper authorities of the situation, both present and prospective, in which electric traction was placed, and everyone at all interested in the subject will remember the results of this enquiry without our needing to recall the circumstances. The road was, without any doubt, cleared in a most effective manner for the adequate promotion of electric street tramways, and the best proof of this lies in the fact that at once there were several projects brought into active vitality, with others ready to follow in rapid succession when the financial world should recover from the shocks it has experienced during the past five years.

There is now every appearance of similar facilities being rendered available for lines which partake more of the character of railways, inasmuch as they are confined to a large extent, if not altogether, to a separate and distinct route, being fenced off from other traffic, just as with an ordinary railroad, instead of using the public roads or highways as earthworks. A line of the type we have in view would resemble very much the Isle of Man electric tramway lately opened between Douglas and Laxey, which travels part of the way along high roads, and for the remainder upon a distinct route or roadway of its own. This is in essence a *light railway*; and it is in connection with such enterprises that we now have to notice with great approval the result of representations made to the Board of Trade. This Department—as will be seen in detail on referring to another page—has requested by circular the attendance of deputies from all the associations and interests concerned in light railway projects at a conference under the auspices of the Board of Trade, when the technical and other difficulties which at present appear to hinder their development may receive careful consideration, with a view to finding out what measures will give suitable relief.

For the purpose of discussing in a preliminary fashion the two chief points raised by the Board of Trade circular, and for appointing deputies to represent the Chamber at the conference, the London Chamber of Commerce has called a meeting of its Engineering and Electrical Trades' Sections, and we congratulate the Chamber on its promptness in dealing with the subject—a promptness which all others interested will probably imitate, if they cannot excel. We make no doubt that prominent and suitable members will be appointed to attend the conference; but it will be useless their doing so, or anyone else, if the entire proceedings are simply to end in resolutions only, of the type with which we have become perhaps too familiar—expressing unbounded approval of the better development of light railways, but not helping in any way to show how this can be achieved.

It would seem very clear that the conference now to be held can only be a first step, a preliminary dis-

Digitized by Google

cussion at which the plan of action is to be unfolded, criticised, and decided upon. The points mentioned specifically in the Board of Trade circular are purely technical. They do not involve or introduce in any way the fundamental question of Government support, or contributions from local authorities, parish and county councils, for building and equipping these lines in different parts of the country. Yet it must be confessed that the political or national aspect of successful light railway developments has a primary importance, ranking above questions of gauge, working regulations, or even course of procedure in obtaining parliamentary powers. These are topics which probably even the Board of Trade would not care to discuss with finality, and we shall therefore be disappointed if at the proposed conference no suggestion is made for a full and complete examination into the whole subject, such as can best be done before a joint parliamentary committee, leading on to Government action and a special Bill.

If the Board of Trade itself cannot properly or fittingly make such a proposal, the delegates from the London Chamber of Commerce may well undertake the task. The success already mentioned which attended a similar course of action when electric street tramway development was in danger of strangulation, would prompt a repetition of the plan. Doubtless the Board of Trade would acquiesce, since not only the technical points might be brought out in all their fulness before such a joint committee, but the other topics of a semi-political or statecraft nature might also receive adequate consideration, and these are, as stated, of fundamental importance.

Turning to practical points, we need only express an ardent hope that some effective result will follow on this latest move; there are, we feel sure, large numbers of lines which might very advantageously be worked by means of electric traction, especially where power is cheap or can be stored easily. Again returning to the Manx tramway, its profitable results show clearly that a vast field lies open for light railways worked by electric motors: and if the question is asked why such a line should be possible in the Isle of Man, and not in England, the answer must be that the working conditions imposed by law and authority are different in the two islands. It remains now for the new movement to secure something even better than is possible for Manxland: we want a development of lines on the plan that has worked so favourably in Belgium, if (as we expect) it can be shown that equal scope and similar conditions exist in this country.

CORRESPONDENCE.

Justice needs that both be heard."

TWO-WIRE DISTRIBUTION.

SIR,—Please allow me to correct a slight error which has unfortunately crept into my letter in your last issue. The three lamps shown in the sketch should each be of 16 c.p. This is so obvious that it scarcely needs correcting, but it might possibly mislead some of our friends the beginners. With apologies for troubling you—Yours, etc.,

F. G. ANSELL.

Wickar, Gloucestershire, October 27, 1894.

A SIMPLE FORMULA FOR MAGNETIC WINDINGS.*

BY FRED BRAINARD COREY.

Several methods have recently been presented for the calculation of the windings of magnets, and for the determination of the proper size of wire for each particular case. Perhaps a simple formula, devised by the writer for use in his own work, might be of interest to others who have frequently to calculate the field windings for electrical machinery. The formula is applicable only to shunt or separately excited machines. It is possible that others have followed the same method, but those to whom it is new will find it extremely useful.

Supposing each turn of the winding to be of the same length, the number of ampere-turns depends only upon the cross-section of the wire used, and hence, to obtain a given number of ampere-turns on any core, it is only necessary to select the proper size of wire.

The resistance of one circular mil foot of copper wire at a temperature of 100deg. F. is approximately 11 ohms, and for all ordinary field windings this value may be considered sufficiently accurate. The resistance of any piece of copper wire at this temperature is therefore

$$R = \frac{11 \times L}{\text{circ. mils}},$$

where L is the length of the wire expressed in feet. The current flowing in any such wire is evidently:

$$C = \frac{\text{E.M.F.} \times \text{circ. mils}}{11 \times L}.$$

It is also evident that the number of ampere-turns in any winding is numerically equal to the number of amperes that would result if a single turn of wire were subjected to the voltage to be used; hence,

$$\text{Ampere-turns} = \frac{\text{E.M.F.} \times \text{circ. mils}}{11 \times l},$$

where l represents the mean length of one turn in feet. We now have, by transposition, the cross-section of the wire for the required winding:

$$\text{Circular mils} = \frac{\text{ampere-turns} \times 11 \times l}{\text{E.M.F.}},$$

In case the winding is to be applied to a shunt motor without external field regulation the above is of course sufficient, but in other cases allowance must be made for whatever regulating resistances are introduced into the field circuit.

This, however, is a very simple matter when once we have determined the ratio of the regulating resistance to the resistance of the magnet winding. It is then necessary only to increase the above result in that ratio to obtain the necessary increase in the cross-section of the wire to be used.

Suppose that we have assumed the ratio $r : R$ as the correct value for the required regulation, then our formula becomes

$$\text{Circular mils} = \left(\frac{\text{ampere-turns} \times 11 \times l}{\text{E.M.F.}}\right)\left(\frac{R+r}{R}\right).$$

The mean length of turn can generally be readily estimated with sufficient accuracy to ensure very reliable results.

We can now select the size of wire whose cross-section is nearest to the correct value as found above, and determine the amount of wire to be used by any of the various rules which have been suggested for economy of wire and safe limits of heating.

The question of heating is, of course, a matter of prime importance, and, unfortunately, it is impossible to devise any rule or formula that will, even approximately, give the desired results. The rule is often given to allow one square inch of radiating surface per watt consumed in the coils, but the application of this rule must be governed not only by the shape of the coil and of the surrounding iron, but also by the insulation on the wire, the outer covering of the coils, and the material of the supporting spool. It is, however, a simple matter in the construction of a machine to determine the heating effect of the field current by experiment, and then add or subtract wire as seems best for satisfactory working.

THE ELECTRICITY WORKS AT BOLTON.

(Concluded from page 513.)

Charges for Current.

A supply of current will be provided at the following charges per Board of Trade unit:

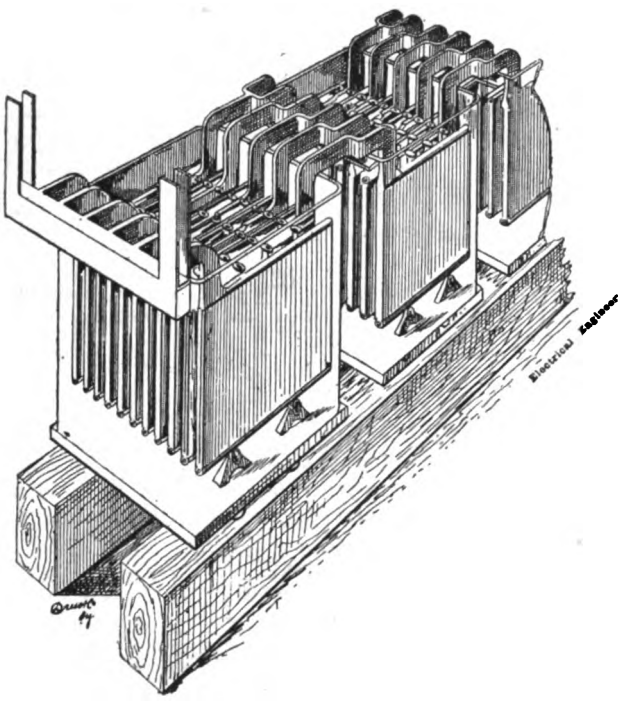
						Per quarter.
Above 12½ B.T.U.	per	16-c.p.	lamp	(or equivalent)	fixed	5½d.
Between 10 and 12½	,,	,,	,,	,,	,,	6d.
,, 7½ ,, 10	,,	,,	,,	,,	,,	6½d.
,, 5 ,, 7½	,,	,,	,,	,,	,,	7d.
,, 2½ ,, 5	,,	,,	,,	,,	,,	7½d.
Below 2½	,,	,,	,,	,,	,,	8d.

The rental of meters will be as follows: for 15 16-c.p. lamps or their equivalent, 2s. per quarter; for 40 16-c.p. lamps or their equivalent, 2s. 9d. per quarter; for 80 16-c.p. lamps or their equivalent, 3s. 3d. per quarter; and for 160 16-c.p. lamps or their equivalent, 4s. per quarter.

A discount of 2½ per cent. will be allowed on all accounts paid within 21 days of the date thereof.

Conclusion.

Mr. J. H. Rider is to be congratulated upon having brought the undertaking to a successful issue, and the Corporation deserve credit for having decided to put down municipal works. Considering the present support, and that in prospect there is every reason to feel confident of the future commercial prospects of the enterprise, which,



Bolton.—Crompton-Howell Accumulators

bearing in mind the extent of the area capable of being supplied, and that indeed from which applications for light are being made, would have rendered extremely injudicious and expensive the adoption of any system other than that now inaugurated.

REGULATIONS OF SUPPLY OF CURRENT BY THE BOLTON CORPORATION.

Application for Supply.—Persons requiring a supply of electricity must fill up and sign an application form, giving particulars as to the number and power of lamps proposed to be fixed, and approximately the maximum number likely to be in use at any one time. Also particulars of any other intended use of the current. Forms of application may be obtained at the office of the borough electrical engineer, and should be returned to him, duly filled up, at least 14 days before the supply is required.

Character of Supply.—The Corporation will supply an alternating current of about 6,000 complete periods or alternations per minute, and at a mean pressure of 100 volts at the main cut-out box.

Three-Wire System.—The Corporation reserves to itself the right of supplying any building containing more than 150 lamps of 8 c.p. (or their equivalent), or requiring an intermittent or varying amount of current, at a mean pressure of 200 volts at the main cut-out box, the circuits being subdivided to 100 volts each, on the three-wire

Bolton.—Section of High-Pressure Cable.

system. In any case such a building must be wired in at least two entirely distinct circuits, and these should be so arranged that as equal a demand as possible will take place on each.

Bolton.—Section of Low-Pressure Cable.

Wiring.—The whole of the internal wiring and fitting work should be carried out by a responsible firm, and must be in accordance with the current rules of the Phœnix Fire Office, and of any other regulations which the Corporation may require.

Bolton.—Mordey-Victoria Transformer.

Conductors.—No conductors used shall carry a current greater than 1,000 amperes per square inch of their cross-section, and the sizes of the conductors must be so proportioned that the fall of pressure between the main cut-out

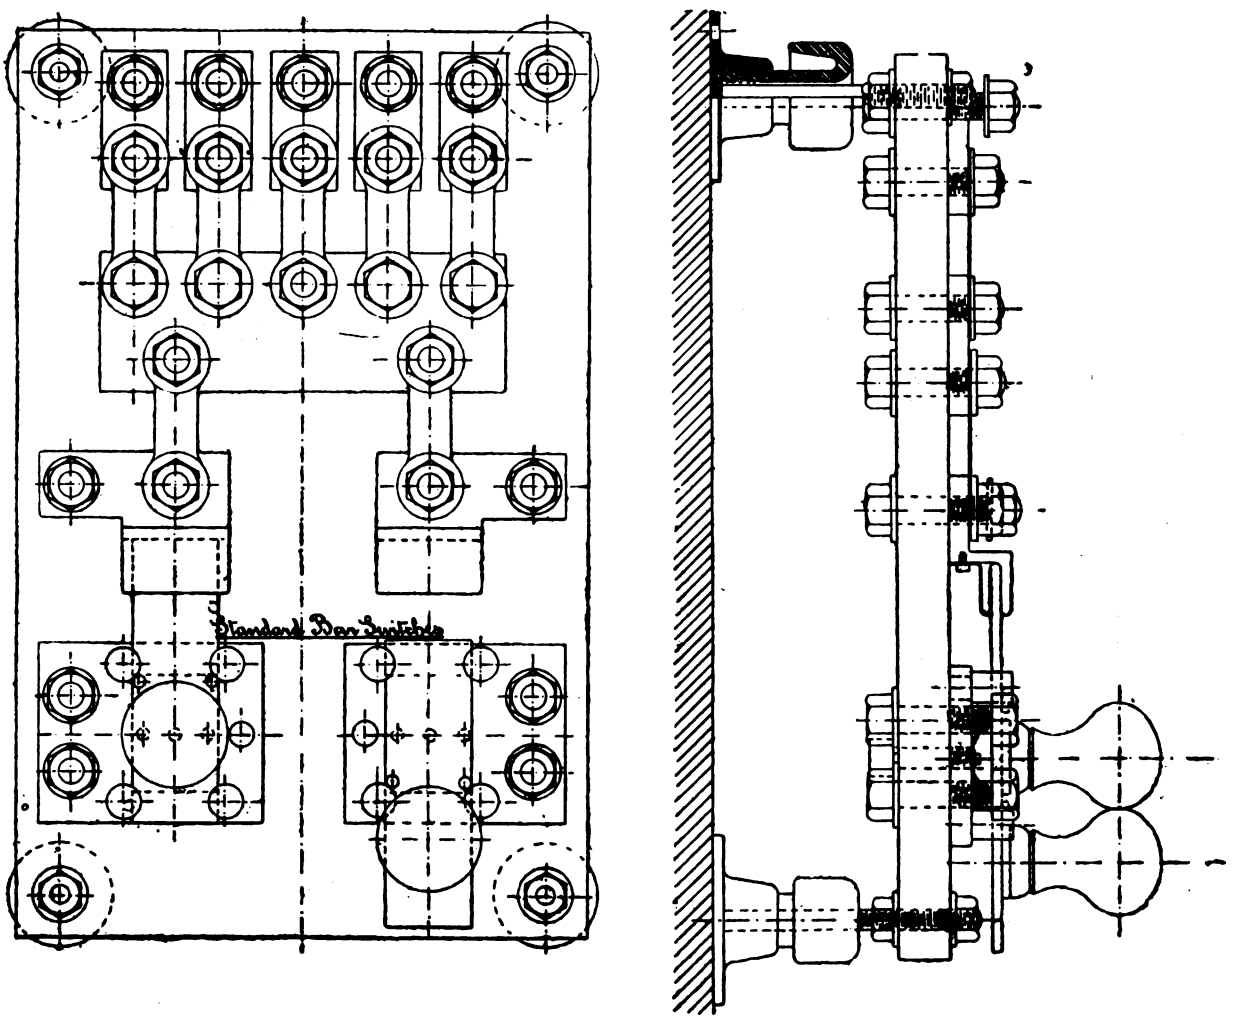
Digitized by Google

box and the farthest lamp shall not exceed 2 per cent. when the maximum number of lamps is on. All conductors to be insulated with pure and vulcanised indiarubber, braid and compound, to give a minimum insulation resistance of 300 megohms per mile. Lead-covered or armoured cables must not be used unless concentric, and in any case not without the special permission in writing of the borough electrical engineer. Where metal tubes are used as a protection, both conductors must be placed together in the same tube, which should be of sufficient size to prevent damage in drawing in or out. Under no circumstances whatever are staples or metal saddles to be used to fasten down conductors.

Samples.—The Corporation, through their electrical engineer, may require samples of the various wires and cables proposed to be used, with a statement of the maximum current to be sent through each.

mains to it free of charge, when the distance from the nearest distributing main does not exceed 60ft. The house mains must be brought to the cut-out box by the consumer, but connection thereto is only to be made by the Corporation officials. Sufficient cable must be left for the meter connection. The Corporation will supply meters at fixed rentals, and reserves to itself the right of deciding upon the positions of all meters. When the householder has made proper application for the supply of current, the borough electrical engineer, or his representative, will, if desired, point out the position to be occupied by the main cut-out box and meter.

Main Switch.—A double-pole switch must be fixed by the consumer in each circuit of the house mains, and on the consumer's side of the meter. Such switches to be securely protected, and to be of a type approved by the borough electrical engineer.



Bolton.—Low-pressure Switchboard for Transformer Sub-station.

Arc Lamps.—When arc lamps are used they should be specially made to burn with alternating currents of the stated periodicity, and a regulating resistance must be used in each circuit instead of a choking coil. Special permission in writing must be obtained before a choking coil is used on an arc lamp circuit. The type of arc lamp, resistance, choking coil, etc., must be approved by the borough electrical engineer before being used.

Motors and Other Apparatus.—Any apparatus not used for ordinary lighting purposes, such as motors, regulating switches, resistances, choking coils, heating appliances, etc., must be approved by the borough electrical engineer before being used.

Gas Fittings.—Gas fittings must not be used for the support of electrical lamps or wires, unless the gas supply is entirely cut off, and the fittings are thoroughly insulated from "earth." Special permission, however, may be given for a modification of this rule under certain circumstances.

Main Cut-Out Box and Meter.—The Corporation will supply and fix a main cut-out box, and bring their service

Testing.—No building will be supplied with current until the wiring has been tested and passed by the borough electrical engineer. One test will be made free of charge. At least 24 hours' notice must be given, in writing, to the engineer before a test can be made, and the engineer will then appoint a time. The contractor's representative should be present at the time appointed. The whole work must be completed, with fuses in and lamps fixed, before a test can be made. If the work be found not ready for testing, or should it fail to pass the test, a fee of 10s. 6d. must be paid at the office of the electrical engineer before any further test can be made. To avoid misunderstandings with their clients, wiring contractors are advised to test the work themselves before giving notice to the Corporation.

Refusal to Supply.—The Corporation may refuse to supply current to any building if (1) the work be not carried out in accordance with these regulations; (2) the whole of the work be not completed, and the fittings permanently fixed; (3) when tested with a continuous current of 100 volts

Digitized by Google

pressure, the insulation resistance of any circuit falls below the following—viz.,

$$\text{insulation resistance in ohms} = \frac{15{,}000{,}000}{\text{max. current in amperes}}.$$

This applies to the insulation resistance measured either between the circuit and "earth," or between the circuit and any other circuit.

Leakage.—The Corporation reserves to itself the right at any time, and if necessary without notice, to cut off the supply to the whole or any part of a building if the insulation become defective or the work otherwise unsafe.

Additional Lights.—If alterations to the wiring, or additional lamps be contemplated, notice must be given, in writing, to the borough electrical engineer, and such additional work must be tested and passed by him before current is supplied to the altered or new circuits. Non-compliance with this rule will render the whole supply liable to be cut off.

Access for Inspection.—Free access must be allowed to the premises at all reasonable times to the proper officers of the Corporation, to examine, test, or inspect in any way they may deem necessary the wiring, fittings, meters, and all other matters connected with the electric supply; and all reasonable and suitable facilities must be afforded by the consumer to the officers of the Corporation to enable them to do so.

CITY AND GUILDS OF LONDON INSTITUTE.

LECTURE VIII.—THE CONSTRUCTION AND ACTION OF ELECTRIC BELLS—THE ARRANGEMENTS OF BATTERY CELLS, AND OF CIRCUITS FOR BELLS.

(Specially contributed.)

Modifications of Daniell Cell.—Various modifications of the Daniell cell have been made to diminish internal resistance. Several of these get rid of the porous jar, and depend upon difference of density to keep the solutions apart. The copper sulphate, being heavier than zinc sulphate, is placed at the bottom of the containing vessel, with copper strips therein. Connection with the external circuit is made by a wire covered with some material not acted upon by the chemicals. The upper part of the vessel contains the zinc plate, surrounded by a solution of zinc sulphate. It will at once be seen that such modifications as this are not very well suited for practical use, inasmuch as any mechanical vibration would soon cause the solutions to mix, and thus impair the usefulness of the cell. The Calland, Meidinger, and Lockwood cells are of this description. In these cells, when the hydrogen appears in the copper solution it displaces the copper, and forms in its place hydrogen sulphate, or sulphuric acid. Thus

$$CuSO_4 + H_2 = H_2SO_4 + Cu;$$

which, read as before, is hydrogen added to copper sulphate displaces the copper, forming hydrogen sulphate, and leaving the copper free. The free copper is deposited on the copper plate, keeping it clean; while the hydrogen sulphate diffuses through the solution and reaches the zinc plate, when the zinc is attacked and zinc sulphate formed, freeing the hydrogen to resume the cycle of operations over again. The zinc is thus continuously dissolved. The copper sulphate is also consumed, and has to be fed by a supply of the crystals. It is sufficient if, in the first place, when setting up one of these batteries, instead of zinc sulphate we pour in water, and after the cell is at work from time to time the zinc sulphate must be syphoned off and replaced with water. In a dry room evaporation at the top of the liquid causes the formation of crystals of zinc sulphate just above the liquid in the containing vessel, and the liquid creeping up by capillary action crystals are formed higher up. In this way creeping will go on to the top and over. To prevent this, brush a little raw linseed oil upon the glass above the liquid. I might have said that such cells as these are often called *gravity* cells.

Grove and Bunsen Cells.—The Daniell cell, by what may be termed an electro-chemical method, gets rid, as we have seen, of the hydrogen of polarisation, and is a fairly constant cell. Its E.M.F. is only a little over a volt. Another way of getting rid of the hydrogen, and at the same time obtaining a higher E.M.F., is due to Grove, who was the first to surround the copper plate, or the plate used instead of copper, with a strong oxidant—that is, with some compound that would part with its oxygen easily and freely to oxidise the free hydrogen, and thus form an harmless compound, such as water, from

$$H_2 + O = H_2O,$$

which we may read: one part by volume of oxygen added to two parts by volume of hydrogen combines to form two volumes of water.

Grove could not use copper for his cell because he used nitric acid as an oxidant, and nitric acid acts rapidly on copper. You will recollect that I told you the voltaic cell requires two metals, or two something equivalent to metals, one of which is acted upon chemically. So Grove replaced the copper of the Daniell cell by platinum, and the copper sulphate of the Daniell cell by nitric acid. Thus the Grove cell consists of zinc in dilute sulphuric acid outside the porous jar, and platinum in nitric acid in the porous jar. When the cell is at work the zinc is attacked, and sulphate of zinc formed, as in the Daniell; the free hydrogen coming into contact with the nitric acid, takes oxygen from the acid and with it forms water, leaving, however, another compound of nitrogen and oxygen, which is given off in poisonous red fumes, so that this battery should not be worked anywhere unless provision is made for carrying off these fumes. You will see that, though the hydrogen *is* got rid of in this battery, if it is constantly used the nitric acid will soon get weak, and the sulphuric acid be replaced by zinc sulphate. Thus the E.M.F., which is large (1·96 volts) to start with, falls off.

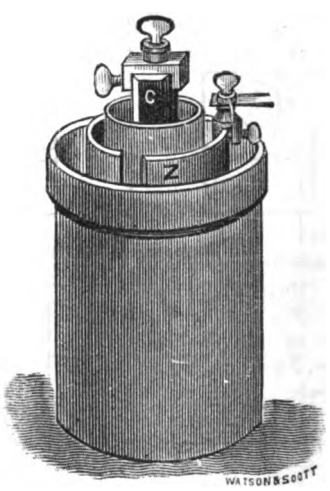


FIG. 1.—Bunsen Cell.

Platinum being very expensive, Bunsen suggested the use of hard gas coke or carbon in its place, and this modification is known as the Bunsen cell, which usually takes the form shown in Fig. 1. The E.M.F. of this cell is about the same as that of the Grove, but it has its weak points. The Grove cell is more compact; its porous jar is usually rectangular, while that of the Bunsen is cylindrical. Then there is more difficulty of making a good metallic connection with the carbon, and the internal resistance is greater. On the other hand, it contains more nitric acid, so that its current lasts longer.

Bichromate or Chromic Acid Batteries.—The fumes from nitric acid cells, or rather from cells using nitric acid as the oxidant, being so objectionable, it was desirable to replace the nitric acid by some other oxidant which should not give rise to this objectionable feature. For this purpose chromic acid and bicromate of potash have been largely used. The Fuller form of bichromate cell is perhaps more largely used than any other. It is shown in section in Fig. 2, where you see a lump of zinc cast round the connecting wire placed inside the porous jar. With the zinc is placed some two ounces of mercury, so that it is kept self-amalgamated. I will explain this question of amalgamation in a moment. The carbon plate is outside the porous jar, and around it are placed four ounces of bichro-

Digitized by Google

mate of potash and four ounces of sulphuric acid. Both outer jar and porous pot are thus filled to near the top with water. According to Preece and Sivewright the following is the action of the cell: "When the circuit is completed the sulphuric acid passes into the zinc cell, attacks the zinc, and forms sulphate of zinc, while the liberated hydrogen reduces the bichromate of potash to a lower form. There is a secondary action in the battery when the solutions become saturated, which results in the formation of crystals of chrome-alum on the carbon plate . . . As soon as this secondary action is noticed, the crystals should be removed and some of the liquid withdrawn and replaced with fresh solution of sulphuric acid." The E.M.F. of the Fuller cell is high, being 2·14 volts. The internal resistance of most forms of cell can be varied according to the thickness of the porous jar, the strength of solution, and the distance of the plates apart.

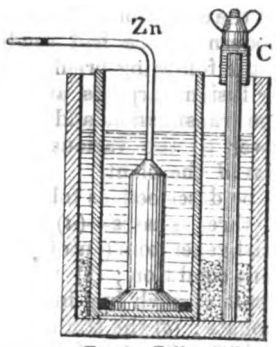

FIG. 2.—Fuller Cell.

I have now described two kinds of cells adapted to get rid of the troubles of polarisation. It is not necessary for us to pursue the subject further. The number of different forms of cell is legion.

Amalgamation.—We have previously seen the essential parts of a voltaic cell, and that one member of the couple is usually chemically attacked by the acid. Now, it is very difficult to get a perfectly pure zinc plate, and when the plate contains impurities and is immersed in the acid a couple is formed between a particle of the impurity and the zinc around it. These minute couples with the electrolyte form complete circuits, and, as we have seen, when the circuit is completed the zinc is attacked. We cannot use the electrical energy developed by such couples. It is wasted—thus forms another evil to be considered. The action of these couples is usually called *local action*, and it has been found that such local action can be avoided by rubbing the clean zinc plate with mercury. When mercury is rubbed over the plate, it dissolves the zinc, forming a coating on the plate of zinc amalgam. The impurities are not dissolved, so that after the rubbing the zinc itself and the impurities are covered with the zinc amalgam, and it is the zinc amalgam that comes into contact with the acid. It is the zinc of the amalgam that is taken by the acid to form sulphate, and as fast as the zinc of the amalgam is taken by the acid just as fast is fresh zinc dissolved from the plate by the mercury. The mercury thus forms a medium by which the zinc is passed from the plate to the acid, but the impurities are not passed. Remember the zinc is not dissolved by the acid unless the circuit is complete.

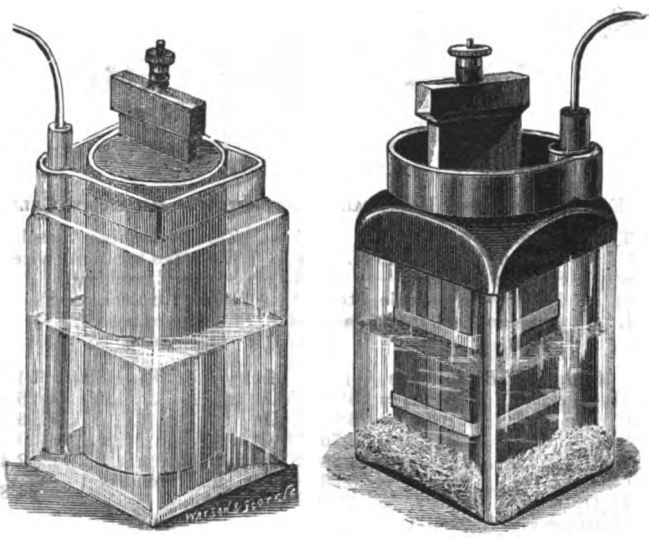
The Leclanche Cell.—Now we can return to the examination of the Leclanché cell in our bell circuit. It is, as I have said, a zinc-carbon couple, the electrolyte being a solution of sal-ammoniac (ammonium chloride). The action is for the ammonium chloride to free its ammonia, forming zinc chloride. Other chemical actions take place. In the end hydrogen is liberated, which comes into contact with manganese peroxide, reducing it to a lower oxide, and forming water. I will not trouble you with the whole chemistry of the cell, but merely that which refers to the getting rid of the hydrogen.

Manganese peroxide is chemically symbolised thus:

$$MnO_2, \text{ and } 2MnO_2 + H_2 = Mn_2O_3 + H_2O,$$

which we may read: hydrogen added to manganese peroxide combines with part of the oxygen of the manganese peroxide, forming water and a lower oxide.

Thus in a way the Leclanché cell provides for the getting rid of the troublesome hydrogen, but unfortunately the manganese peroxide parts with its oxygen comparatively slowly, so that if hydrogen is produced too fast—and it is so produced when the cell is working—only a part of it is neutralised. If, however, the cell is worked intermittently, and only for short times, the hydrogen is gradually neutralised, and the cell soon recovers its normal state. Now, bell work is very intermittent work, and so Leclanché cells have been largely employed for that work. They require very little attention, last a long time, and are easily renewed. Various modifications of this cell have been suggested to reduce the internal resistance, two of which may be mentioned. M. Leclanché got rid of the porous jar, which is used merely to keep the materials together in a compact form, by compressing a mixture of carbon, manganese peroxide, gum, and a little potassium hydrogen sulphate into a hard mass after keeping



Ordinary Form Agglomerate Form.
FIG. 3.—Leclanche Cells.

the mixture for some time at the temperature of boiling water. Plates of this compressed material are fastened to a carbon strip by means of indiarubber bands. This form is known as the *agglomerate* Leclanché, Fig. 3.*

The second modification I will mention is made by combining the porous jar and the carbon, making, in fact, a compound carbon containing cylinder, the inner part being porous, the outer forming the hard carbon of the voltaic couple. The zinc is put at the centre, Fig. 4, and

FIG. 4.—Leclanche Cell—Carporous Form.

surrounded by the peroxide of manganese mixture which serves as an insulator to the zinc. This form is known as the Carporous form.

Dry Cells.—During the past two or three years another class of cell has been coming into favour for bell work. These cells are termed dry cells, but that is hardly a correct

* By a mistake the agglomerate form was shown in our issue of October 19 as Fig. 3. The ordinary form is now shown above, together with the agglomerate form.

Digitized by Google

term, as all such cells have moist electrolytes. There is, however, no free liquid, so that the cell can be closed. The two cells of this class that are mostly used are the Hellesen cell, Fig. 5, and the E.C.C. cell, Fig. 6. These have been carefully examined and described by Prof. Jamieson, who gives their construction as follows:

Dry cells possess certain practical advantages over wet batteries for bell calls, telegraphic, telephonic, medical, and military purposes. Thus their unbreakableness, compactness, portability, cleanliness, and freedom from accumulating crystals, and the creeping of salts to the outside of the containing vessel, as well as the fact that they are always ready for use, and may be laid on their sides or even upside down, are evident advantages.

ELECTRICITY AS A MOTIVE POWER.

(Concluded from page 476.)

Mr. B. H. THWAITE stated that some months ago he was requested to design a small iron and steel works for abroad, in a position where the utilisation of the fullest possible measure of heat in the fuel available was of the highest importance. A careful study of all the conditions of manufacture, and of the resources that modern science had rendered available, led him to decide on the following briefly described scheme of producing heat for fusion purposes, and for the production of power, and the transmission and application dynamically of such power to the various mechanically and widely separated parts of the plant.

The scheme might be described as follows: (1) the production of power, in three phases—(*a*) the conversion of the solid fuel in special generators (automatically controlled and fed) into a gaseous condition; (*b*) the recovery of the nitrogenous constituents of such fuel in the form of commercial ammonic sulphate; (*c*) the storage of such gaseous fuel in containers, and its utilisation for furnace work, and for the production of power by an internal combustion or thermo-dynamic motor, or gas-engine. N.B.—Such plant should be centralised so that it would be convenient for the delivery of the fuel, and be centrally placed for distri buting its gaseous production to various parts of the work, and be sufficiently removed as to prevent the incursion of iron or slag dust suspended in the atmosphere.

(2) The transformation of the thermo-dynamic into dynamo-electric power. This was intended to be effected by electric machines actuated by the gas motors.

(3) The transmission of such dynamo-electric or electromotive force (E.M.F.) to the different mechanical elements of the plant by means of underground or overhead well-insulated conductors.

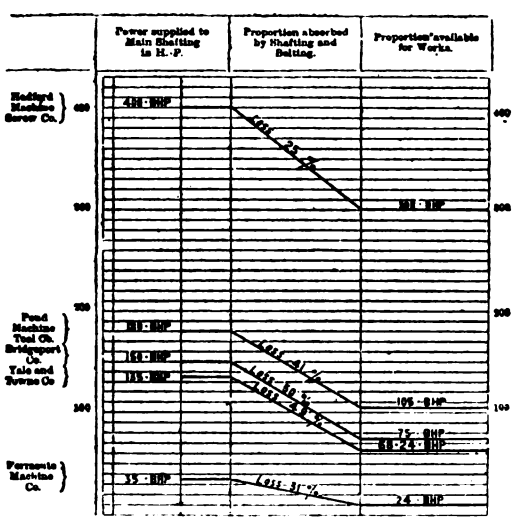
(4) The transfer of such power to the machines themselves. This was effected by electric motors placed either directly in connection with the machine, the armature of which formed the driving shaft, or the power is transmitted by belting from a pulley on the armature shaft to a pulley on the driving shaft of the machine.

In the scheme all the machines were intended to have separate electromotors, and even the hammers were to be worked by powerful magnets with same power agency. The rolling mills were to be equipped with a powerful electric motor fixed on the same bedplate. All the cranes, both derrick, jib, central, travelling, overhead, and loco., had to have their own respective electric motors. The cold and hot saws, the shears, the skull-breaker, the ladle carriage, the trolleys, the rotary fans, were all to be equipped with their special motors and regulating switches. The ores, pig iron, limestone, fuel, and finished products were to be transmitted from one part of the works to the other by electric locomotives. In the machine-shops, the punch and shears, the portable and stationary drills, the lathes, grinding wheels, planing, boring, and slotting machines were each to be electrically actuated by separate motors.

By the scheme briefly described, it was calculated that an actual equivalent energy of 1 h.p. per hour could be directly applied in hoisting, propelling, conveying, and actuating the whole of the mechanical elements, including pumping, with an expenditure of only 1½lb. of coal. The loss of dynamic power in the electric conversion and transmission in any iron and steel works need not exceed one-fifth of the initial available power, so that, given the development of the 1 b.h.p., by the expenditure of 1lb. of gas in a gas-motor cylinder, and one-fifth of this being added for losses of transformation and trans-

Digitized by Google

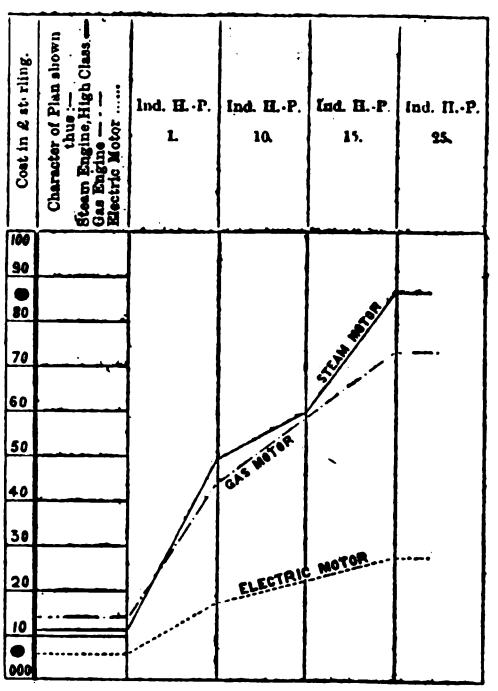
mission as indicated, it would seem that there was actually a margin for reduction on the 1½lb. estimated. Comparing the present system of generating and transmitting power by steam-boilers, steam-pipes, and steam-engines with the system of gas generators, gas motors, electric machines, and electric conductors and motors it would be realised, on examination, that many of the attendant disadvantages of the first-named system would be either avoided or reduced. Some of these disadvantages might be enumerated as follows: (*a*) Generally in iron and steel works the steam-engines were of an inferior design, and were exceedingly wasteful in fuel. If the efficiency of these smaller steam motors was examined, it would be found that it was very low, at least 6lb. of fuel being absorbed for one actual horse-power used applied for one hour, and this independently of the losses in the generation of steam and in the transmission of the steam power by exposed steam-pipes. (*b*) As iron and steel works generally consisted of draughty open sheds, or covered spaces, open at the gable ends and sides, the pipes for conveying the steam power were necessarily exposed to severe cooling conditions and changes of temperature, so that both leakage and condensation were associated evils. (*c*) Finely-divided iron and slag particles floating in the atmosphere of iron and steel works, especially in the rolling and forging department, were productive of much deterioration of steam-engine machinery and its efficiency. The metallic



Graphic Diagram, showing the Absorption of Power by Belting and Shafting, based on Dynomometric Investigations.

and slag particles fall on the moving and frictional parts, and wear them away—it was a rare sight to see a perfect steam-tight gland in an ironworks' steam-engine. (*d*) The steam-engines, large and small, scattered throughout the works, exposed to the draughty and cold influences, could not be expected to give the same efficiency as the well looked after and high-class textile-mill engine in its beautifully kept house. (*e*) The difficulty of starting the engines, through condensation of steam, was an excuse for uninterrupted light load and wasteful running of the machines, so that much wasted energy was associated under this head. (*f*) In the present repair or machine shops, the main line and much of the countershafting was constantly in motion, whether the machines or tools were working or not. (*g*) The present system of scattered small steam-engines was prejudicial to good and economical work, and it would not compare in economy with the central system of a large power plant equal to the aggregate of the smaller engines. (*h*) If steam-engines were not used, a long line of shafting was employed, and the waste of power by this means of transmission, whether by belt or toothed transmission gears, was most serious.

Considering the enumerated disadvantages to ascertain if the proposed central electric system will remove or modify them, he pointed out that: (*a*) The high-class steam or gas motor plant erected in a central station would at once lower the cost of fuel by fully one-third. It was well known that 1 i.h.p. could be developed in gas motors with generated gas fuel, with an expenditure of less than 1lb. of coal. (*b*) The transmission of the electric energy by well-insulated electric conductors would not be affected by changes of atmospheric temperature of the open and draughty sheds, and between the electric machines and the electric motor the loss of energy would be very fractional. (*c*) The central power station would not be exposed to floating metallic and slag particles. The electric motors could be completely boxed in, so that they were not affected by dampness or by the iron or slag dust deposits. *d*. and *e*. There was only one power generating station. Each electric motor could be thoroughly guarded, and when not required in action it could be instantly switched off or be restarted as requirements demanded. There was no need for free and wasteful running. (*f*) Each tool in the repair, turning, fitting, or other machine shop was actuated by its own motor, and could be switched on or off instanter. There was no need for the main and counter shafting to be wearing its bearings away by free and costly running. Reference to the accompanying diagrams would elucidate the loss of power in transmission of power by belting.



Diagram, showing respective Cost of Maintenance, Interest, Amortisation, and Repairs of Three Forms of Motor Installation.

Besides the striking advantages of the scheme set forth, the system enabled electric lighting of a well-distributed character to be obtained at a trivial addition to current cost. Electric energy could, with a little ingenuity, be applied for special and local purposes and conditions much more conveniently than any other system.

The Oerlikon Machine Company, of Switzerland, as well as other continental firms; the Electric Construction Company, Wolverhampton; Messrs. Mather and Platt, Oldham, had introduced numerous applications of E.M.F. In the United States many of the machines in daily use in iron and steel works were actuated electrically. The Carnegie Works, the Wrought-Iron Bridge Company, the Cambrian Iron Company, the Bucyrus Steam Shovel Company, the Pencoyd Ironworks, in the United States, were utilising this economical and efficient form of transmitting power.

Mr. Selby-Bigge's practical contribution was very opportune, and should tend to the popularisation of electrical applications in iron and steel works. The paper called for very few remarks beyond those of a congratulatory nature. He was glad to notice that stress was laid on the loss occasioned by condensation in steam-pipe transmission. The absence of dynamometric tests in British iron and steel works was to be deplored. In the United States this practicable method of testing the power absorbed by different machines had become common, and the information so far gathered was in the highest degree valuable and instructive. He would strongly recommend engineers to peruse Flather's work on the dynamometer, the information given being extremely valuable and practical. The thanks

Digitized by Google

of metallurgists were due to the progressive firm of Dorman, Long, and Co., Limited, for their pioneer work in electrical power applications in steelworks in this country. Their obtained results were alone an eloquent testimony in favour of electric power transmission.

Obviously the best method of producing power for intermittent work when a storage of power was required was to use a gas-engine and gasholder plant. In the latter a large accumulation of power could be held in reserve ready for momentary use, and without such storage involving any loss. This could not be said of any other system of power storage.

By means of a special switchboard and a multiplicity of motors, as the load was reduced part of the gas motors might also be automatically cut off as well as the gaseous fuel plant generating the gas that fed them. The suggestion for comparing the daily coal consumption per electrical horse-power absorbed was an admirable one, and would conduce to the highest economy. The characteristic elasticity of the magnetic field of an electric motor was of the utmost value, and in no instance more than in the application of electric motors for driving a train of rolls, and this feature would probably be the means of preventing many disastrous and sudden strains that would be fatal with present methods. The author did not give any reason why the heavier rolls should not be electrically driven. He might have obtained useful information on the advantages of electric methods of driving workshop tools from the Electric Construction Company, of Wolverhampton, who were on a large scale the pioneers in this country in the use of electric transmission of power for actuating workshop engineering tools.

GAS-DRIVEN ALTERNATORS.

A specification and plans were some time ago prepared for the Municipality of Calais by M. Brillouin, a Paris electrician, for the establishment of a central electric light station in that town. As in the case of the neighbouring towns of Cambrai and Boulogne, the Municipality of Calais asked the Compagnie du Gaz whether they would lay down plant and supply the electric light. The proposal was not only accepted, but the gas company also adopted the plans and scheme devised by M. Brillouin and entrusted him with the carrying out of the work, using, as might be expected under the circumstances, gas-engines as motors.

The plant has been laid down in the old coal-store belonging to the gas company, and situated some distance from the place of consumption. Consequently the high-pressure alternating-current system with transformers was introduced. The cables have been arranged on large masts in a rough-and-ready style in the streets and on the footpaths, three transformer stations being provided in kioskes. The station, which was set in operation last June, contains two Niel gas-engines, each of 80 h.p.; these engines are of the double-cylinder type, with opposite cranks, and running at 160 revolutions a minute. There are two alternators, by Messrs. Brown, Boveri, and Co., capable of furnishing 50 amperes at a pressure of 1,000 volts when driven at 160 revolutions a minute. The exciters give from 30 to 35 amperes at from 80 to 115 volts at a speed of 1,500 revolutions.

A new arrangement has been adopted in driving the alternators. Instead of being belt driven, as might be expected in the case of gas motors, these machines are coupled direct to the gas-engines by means of Snyers elastic couplings. This arrangement will be understood by reference to the plan of the generating plant given in Fig. 1, where clutches are shown at A_1 and A_2. A similar coupling, A_3, is employed to couple together the two alternators. This method allows of each of the machines being actuated by either one or the other motor, or of both being driven by one gas-engine only. It will be seen that the Snyers coupling, which is represented in Fig. 2, is composed of two discs, one of which carries steel-wire brushes and the other radial teeth similar to those projecting from a comb. When a dynamo at rest is being connected with a motor which is already running, the steel brushes are gradually brought into contact with the teeth, thus revolving the dynamo slowly until the speed of the latter reaches that of the motor. This fact is observed when the noise caused by the friction between the two discs ceases, when the coupling can be completed. The exciters are belt driven, as shown on the plan.

ELECTRIC PROPULSION OF BARGES.

Some interesting experiments were conducted on the Canal de Pouilly on October 10 with a new system of propelling barges by electric power. This method, which has been devised by M. Galliott, one of the engineers of the Ponts et Chaussées, is being promoted by a syndicate in connection with the Maison Farcot, who have equipped the barges with which tests are being made.

The system consists in the substitution for the ordinary rudder of an appliance of the same form and connected to the barge in the same manner. The appliance is in effect a combined screw and rudder. It carries on its upper part an electric motor which drives, by means of shaft and gear, a screw which is arranged a short distance from the back of the barge. This form of propeller has been fitted to a barge belonging to the Compagnie Havre-Paris-Lyon. The screw was calculated for a speed of 300 revolutions a minute, the gear allowing a reduction in the ratio of

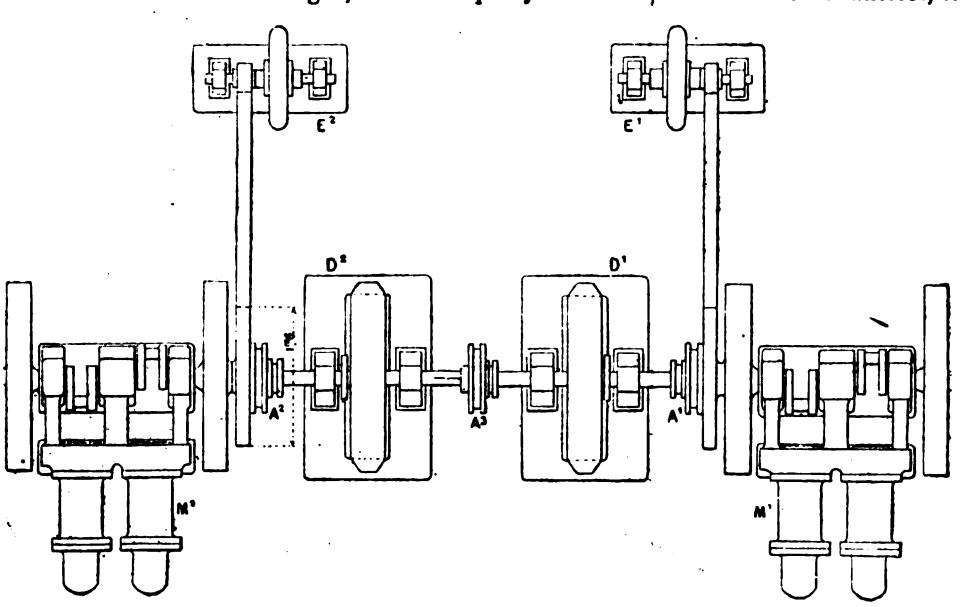


FIG. 1.—Plan of Gas-Driven Alternators.

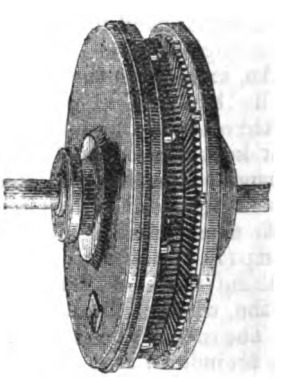

FIG. 2.—Snyers's Elastic Coupling.

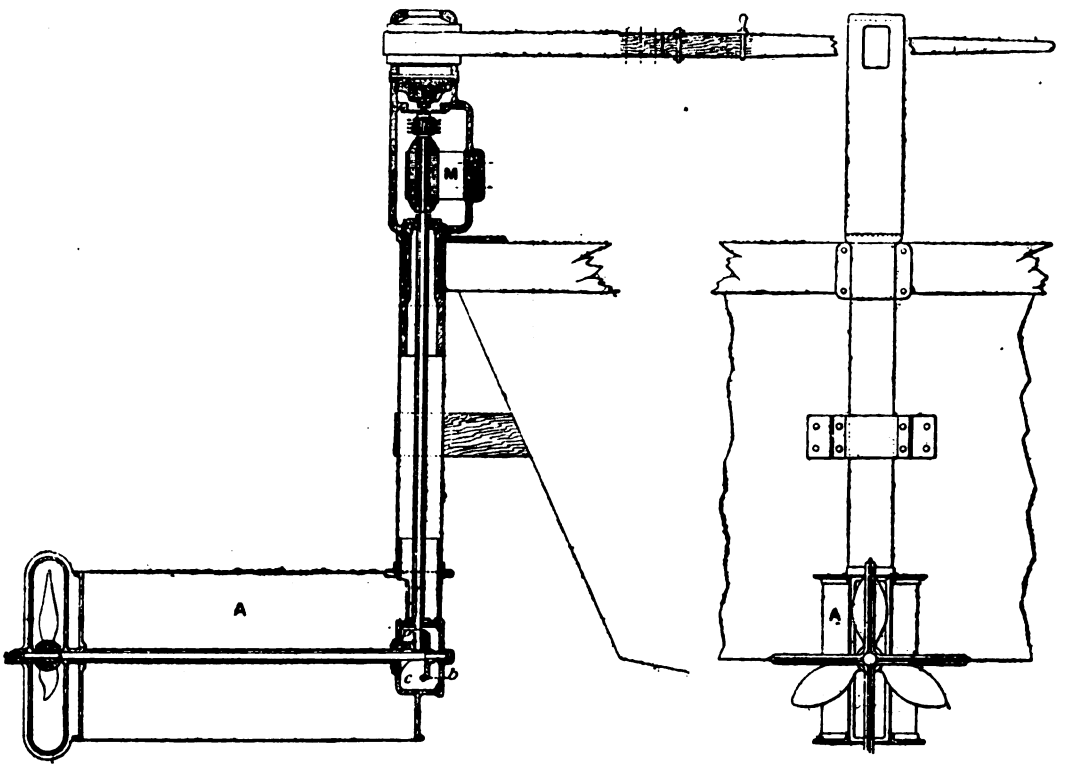
Digitized by Google

1 to 3½. The accompanying illustrations (Fig. 1, a section, and Fig. 2, a back view of the apparatus) are reproduced from our contemporary *L'Industrie Electrique*.

It will be seen that the shaft of the screw is contained in the interior of an iron case, A, carrying at one end the screw and at the other a bevel wheel, *b*, gearing with a similar wheel fixed at the lower end of the vertical shaft shown, which is driven by the electric motor, M. The bevel gear is arranged in an iron box filled with oil. The motor shaft is encased in a tube, down which the oil for lubricating the gear is passed. The barge is 38 metres in length, and with a load of 180 tons it has a normal speed of 85 centimetres per second, or 40 per cent. over that when hauled by two horses, and the electrical energy required amounts to 3,400 watts, or 4·6 h.p. The current is supplied from a battery of Laurent-Cely cells, which are charged at any convenient spot.



FIGS. 1 AND 2.—Section and Back View of Electric Propeller.

CENTRAL STATION WORKING ABROAD.

An article in *L'Industrie Electrique* of October 25 deals with the position of the electrical industry in various foreign countries. The writer gives some interesting information concerning the duration of the concession, municipal charges, cost of coal, and sale price per 100 watts. Dealing first with the Vienna Electrical Company, which competes with the General Austrian and International Electrical Companies, it is mentioned that it was established in 1889 with lighting powers over the whole town. The duration of the concession is 50 years, the town having the right of acquiring the undertaking at the end of either 15, 25, or 35 years. In addition to steam and electrical plant of 1,500 h.p., batteries equivalent to 500 h.p. are also provided. The number of lamps connected, estimated in 16-c.p. lamps, is 25,000, and current is sold for lighting at 9d. per unit, with reductions ranging from 3 to 30 per cent.; and for motive power at 4¾d. per unit, with rebates of from 10 to 30 per cent. Coal costs between 14s. 1d. and 17s. 8d. per ton, and the company pays to the town 3 per cent. of the receipts on the sale of current. The last dividend was at the rate of 2 per cent. on the total capital. At Dusseldorf, where the central station was established in 1891, plant to the extent of 400 h.p., supplying 18,300 lamps, is installed. The price charged is 9¾d. per unit, but reductions reaching 20 per cent. are made. The fuel used costs 8s. 11d. at the pit. The Breslau station, started in 1891, has an unlimited concession. Steam dynamos and accumulators are used, the number of 16-c.p. lamps or their equivalent supplied being 15,118. Coal at the railway station costs 7s. 8d. per ton. The Berlin Electricity Works, which commenced operations in 1884, supply under a 30 years' concession, but the town has the right to acquire the enterprise in 1895, according to the conditions fixed in the agreement. The power of the works is 15,100 h.p. and 194,000 16-c.p. lamps are energised. The charge for current varies; coal costs between 16s. 11d. and 18s. 3d. per ton, and the company pays to the town 10 per cent. of the net receipts. The last dividend was 10½ per cent. After considering several English stations in a similar manner the author refers to the Edison General Electricity Company in Milan. Established in 1893, the company has the right to furnish light until 1904. The generating plant, comprising 3,100 h.p., feeds 34,821 incandescent and 957 arc lamps. The charge for current is 9½d. per unit; coal costs 26s. 5d. a ton, and no payment is made to the town. A dividend of 10 per cent. was distributed in 1893. At Geneva, the Electrical Industry Company, which has a concession for eight years dating from 1887, supplies 15,000 lamps; water power is used, and the price per unit varies between 4½d. to 6¾d. per unit, according to circumstances. No payment is made to the town, and the company distributed a dividend of 5½ per cent. in 1892, but nothing in 1893. The Copenhagen station, started in 1892, uses 1,430 h.p., and distributes by means of batteries. The number of lamps connected is 25,800; current for lighting is purveyed at 7¾d. per unit, and for motive power at 3d. in summer and 4d. in winter. The fuel used is coke and coke dust, the former costing 10s. 5d. and the latter 4s. per ton.

THE SURPLUS AND DEFICIT THEORY OF ELECTRICITY.

BY W. PERREN MAYCOCK, M.I.E.E.

(Continued from page 487.)

(*d*) *Influence, or Electrostatic Induction.*—Notwithstanding the almost general acceptance of the term "influence machine" *vice* "induction machine," the use of the term "influence" in place of "electrostatic induction," as proposed, so far as I can remember, some years ago by Dr. Oliver Lodge in his lectures on "Lightning Conductors," does not seem to have received the encouragement it deserves. The term "induction machine"

Digitized by Google

is in any case a vague one, for it might equally well be applied to a Wimshurst machine, a dynamo, or an induction coil. From a practical point of view, the phenomena of electrostatic induction differ very much from those of magnetic or electromagnetic induction, and it is very necessary to avoid a confusion of terms. A +ly charged body is constantly endeavouring to rid itself of its surplus, and the probable path of its discharge is prepared beforehand by influence or electrostatic induction. In other words, a deficit, or negative electrification, will be developed on all the nearest parts of neighbouring conductors, especially earth-connected ones. On the other hand, a −ly charged body will tend to draw electricity into itself from neighbouring conductors to fill up its deficit, and consequently influences or induces a surplus, or + electrification, on the nearest parts of all those in its vicinity. Let us consider the case of an insulated +ly charged ball, A (Fig. 3), acting influentially or inductively on an insulated uncharged ball, B. The usual explanation given is that "− electricity" is induced on the nearer side of B, and "+ electricity" on the farther side. Now, applying the theory of surplus and deficit, we may say that before A was brought near to B, the electricity on the latter, of which there is neither a surplus or deficit, was evenly distributed. As A is brought up to B electricity is gradually

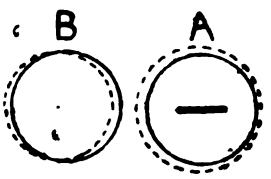


FIG. 3.

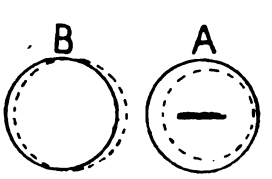

FIG. 4.

displaced from right to left, leaving a deficit, or − electrification, on the side nearest A, and creating a surplus, or + electrification, on the side remote from A. This unequal distribution of B's normal charge, and the consequent variation of density, is clearly indicated by the dotted line. Let A be −ly charged—*i.e.*, in a state of deficit, Fig. 4—we may then suppose that the electricity on B is drawn over to the side facing A, creating a + density there, and leaving a deficit or − density on the farther side of B. A, Figs. 3 and 4, before being brought near to B may be supposed to have had a uniform density, as in Fig. 2. On being approached to B its density (+ or −, as the case may be) is no longer uniform, but is greatest on the side nearest to B.

(*e*) *Charge and Potential.*—We have hitherto assumed that a +ly or −ly charged body is at a + or − potential respectively, and that a body at a potential has a charge of similar sign. This is true only so long as no appreciable influential or inductive action takes place between the body under consideration and neighbouring bodies. When a body is under influence, or electrostatic induction, though as a whole it may be uncharged, on one side it will have what is generally called a "bound" charge, and on the other a "free" charge of opposite sign. A previously neutral body will also acquire a potential (+ or −) when under influence, and a previously charged body at a potential may have its charge bound and its potential reduced to zero, or even reversed, by influence. When we speak of a charge without prefixing the words "bound" or "free," the state of the body as a whole is referred to. These matters, which at first sight are a little confusing, are considered in the following three sections.

(*f*) *A Body at a + or − Potential is not necessarily a Charged Body.*—The elementary student is often at a loss to account for the potential of a body, but all difficulty is removed if it be borne in mind that a body is at a + potential when, if connected with earth, there would be a flow of electricity from the body to the earth: and a body is at a − potential when, if connected with the earth, there would be a flow of electricity from the earth to the body. Thus in Fig. 3 both A and B are at a + potential, while in Fig. 4 they are both at a − potential, but in neither case can B, considered as a whole, be said to be charged; although we may speak of the "free" charge on one side, and the "bound" charge on the other, yet electricity has merely been displaced or altered in its distribution on B; none has been put on or taken away. A, on the other hand, has clearly both a + charge and a + potential in Fig. 3, and a − charge and − potential in Fig. 4.

(*g*) *A Body at Zero Potential is not necessarily an Uncharged Body.*—If B, Fig. 3, were momentarily earth-connected, the surplus on its left-hand side would flow away to earth, and a further displacement of electricity would take place, the surplus flowing to earth, so that in the end we should have a state of things as represented in Fig. 5; the − density on the right-hand side of B being greater than in Fig. 3, even though A's charge be the same in each case. Now here, clearly, we have a body, B, with a negative charge upon it, but so long as we do not alter the relative positions of A and B, connecting B with earth will not give us a flow of electricity either way, therefore B must be at zero potential. If A be brought nearer to B, the potential of the latter will rise, a surplus collecting on the left-hand side; but if B's distance from A be increased, some of the charge or deficit will be set free, a slight redistribution will take place, and B's potential will fall—*i.e.*, become negative. In short, decreasing the distance between A and B will raise the potential of the latter, while increasing the distance will lower it. In the case depicted in Fig. 4, where the influencing or inducing body, A, has a − charge, if B is momentarily connected with earth, we may say that electricity will flow from the earth to fill up the deficit existing on B's left-hand side—in other words, the free negative charge and potential is neutralised; then immediately a further displacement of electricity takes place, the positive density on the right-hand side increasing, creating for the moment a deficit on the left-hand side, which is, however, immediately filled up from earth. This will give the state of affairs shown in Fig. 6, the + density on B being greater than was the case before it was earth-connected. Now, although B has a bound + charge upon it, since it has just been connected with earth, whatever difference of potentials before existed must have been neutralised, and B is consequently now at zero, or earth's potential. If the distance between A and B be decreased, more electricity will be drawn over to the right-hand side of B, its potential will fall, a deficit being left on its left-

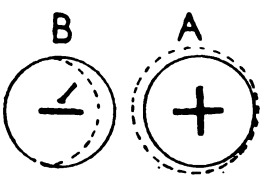

FIG. 5.

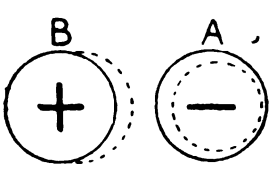

FIG. 6.

hand side. If the distance be increased, B's potential will rise, a certain amount of electricity being set free. All this goes to prove that *a body may be charged and yet be at a zero potential*; or, what is the same thing, *when all the charge on a body is bound by the presence of an opposite charge, the former is at zero potential.*

(*h*) *A Body may have a − Charge and + Potential, or vice versâ.*—In B, Fig. 7, the dotted circle C represents the uniform − density when the +ly-charged body, A, is far removed, B having a deficit, or − charge. If A be brought up to the position A′, the − density on B will be no longer uniform, it being greater on the right-hand side than on the left, where it is practically nothing. This is indicated by the dotted circle C′. If A be brought up still farther into the position A″, the − density on the right gets still greater, and a + density will be created on the left, signifying a + potential.

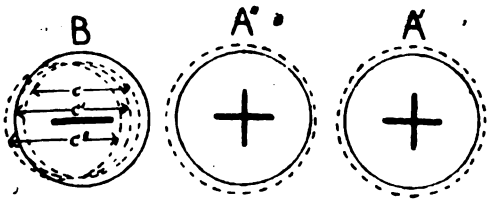

FIG. 7.

The opposite case of a body with + charge and − potential may be deduced from the above. Such an effect as that just described would occur when a highly-charged body acted influentially or inductively on a slightly oppositely charged body. If A is +ly charged it displaces the electricity on B from right to left; if −ly charged it will displace it from left to right—in the first case repelling, and in the second case attracting it. From the foregoing, the truth of the following statements must be evident to the student: (1) The potential of a charged (either + or −) or uncharged body at any initial potential (+, −, or zero) will *rise* on the approach of a body at + potential, and *fall* on its withdrawal. (2) The potential of a charged (either + or −) or uncharged body at any initial potential (+, −, or zero) will *fall* on the approach of a body at − potential, and *rise* on its withdrawal. The seven cases arising out of the conditions mentioned in (1) above are illustrated in Fig. 8, where the body to the left is the one whose change of potential is to be considered. In cases IV., V., VI., and VII. the required conditions of charge and potential are brought about by the presence of an influencing body, B, which is supposed to remain *in situ*, while the body at + potential, A, is brought up. The latter is not shown in the figure, but it should for simplicity's sake be considered to approach from the right-hand side, although the effect would be substantially the same, no matter from what direction it approached. The reader can reason for himself how the stated effect occurs, and he should also work out the seven similar but opposite cases pertaining to (2), where the body brought up is at a − potential. It should be borne in mind that a rise of − potential means a *diminution* of the potential difference between itself and earth, and *vice versâ*.

Digitized by Google

On the other hand, rise of + potential means an *increase* of the P.D. between itself and earth, and *vice versâ*. "Rise of potential," or "increase of potential," may be taken to mean the same thing when applied to + potentials. With − potentials, on the contrary, a "rise of potential" means a decrease of − potential; a "fall of potential" means an increase of − potential.

(*i*) *Capacity.*—The capacity of a conductor may be defined as a measure of the amount of electricity that has to be put into it (+ charge) in order to raise its potential one unit above that of the earth; or the amount that has to be abstracted from it (− charge) in order to lower its potential one unit below that of the earth. The capacity of a conductor, charged or uncharged, is increased by bringing it near to another *uncharged* conductor, this increase of capacity being much greater if the neighbouring conductor is earth connected. If the conductor whose capacity is being considered is charged, and is brought near a conductor at an opposite potential, its capacity will be increased.

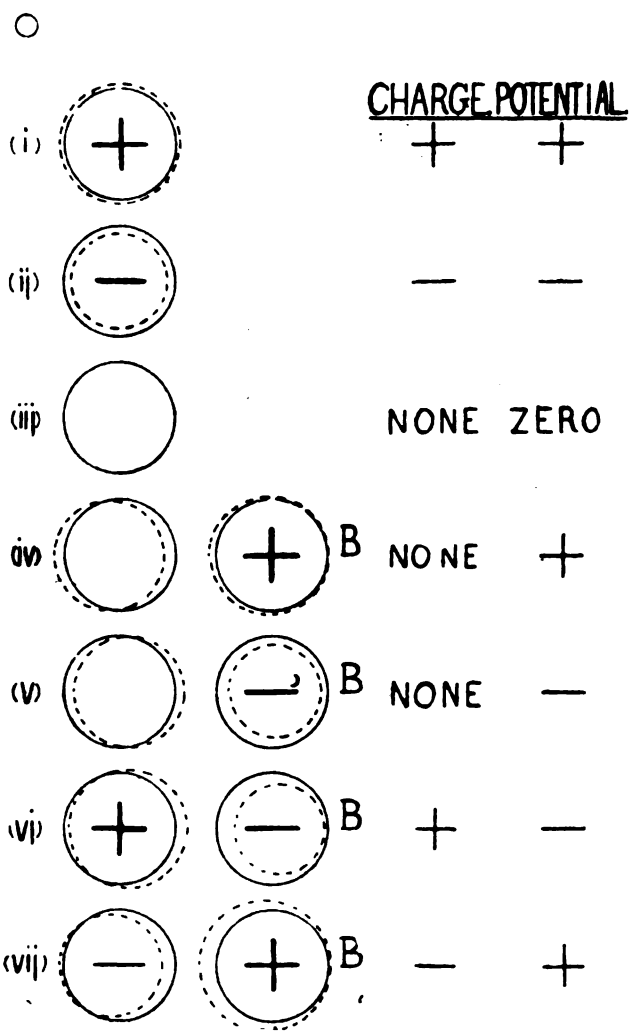

FIG. 8.

If the conductor is unchanged, its capacity will be increased by bringing it near a body with a + or − potential; but in this case its capacity will be increased only for charges of opposite sign to that of the potential of the body to which it is brought up. Referring to Fig. 3, when the charged sphere A is far removed from B (and all other bodies), its potential is a maximum; as it is brought nearer to B, its potential gradually falls, as its charge becomes more and more "bound" by the reaction of the influenced or induced charge on B; in other words, its capacity is increased, for it will require more electricity to be put into it in order to raise its potential to the same degree as before. This increase of capacity is not, however, very great, as B is not earth connected. The effect of connecting B with earth is, as we have already explained, to enable the repelled surplus or + charge to run to earth, and a much greater deficit, or − charge, to be influenced or induced on the side opposite A. More of A's charge is thus occupied in binding the influenced − charge on B, and A's potential falls much lower than in the first case, when B was not earth connected; in other words, A's capacity is much increased, as represented in Fig. 5, by the accumulation of the charge on the side opposite B; and it will need an increased amount of electricity to be put into it to raise its potential to the same value as before. In Fig. 4 we have the opposite case of a −ly charged body. When A is far removed from B (and all other bodies) its (−) potential is a maximum, and its density uniform, as shown to the left hand of Fig. 2. As A is brought up to B, in its effort to fill up its deficit, it will influence a surplus on the near side of B, leaving a deficit on B's farther side. Reaction takes place between the influencing charge on A and the influenced charge on B; or we may say that part of A's charge is occupied in binding or holding the influenced charge on B. However we express it, the influencing and influenced charges attract each other, there being a greater deficit on the left than on the right-hand side of A, and A's potential rises—*i.e.*, its −potential decreases (*vide* end of section *h*)—and it will require a further subtraction of electricity to reduce its potential to the same value as before. If B be connected with earth, electricity will rush up into B to fill up the deficit on its left side, and, under A's influence, to increase the surplus on its right side. A's potential will consequently rise still more—*i.e.*, its − potential will decrease—and the final state of things will be as shown in Fig. 6.

We shall have more to say about capacity in dealing with the subject of condensers (section *k*).

(To be continued.)

LIGHT RAILWAYS.

The following letter has been sent by Sir Courtenay Boyle from the Railway Department of the Board of Trade to the Associated Chambers of Commerce, the Central and Associated Chambers of Agriculture, the London Chamber of Commerce, the Railway Companies' Association, the Institution of Civil Engineers, the London County Council, the Association of Municipal Corporations, and the Association of County Councils: "I am directed by the Board of Trade to communicate with you on the subject of a movement recently set on foot with the object of obtaining further powers and facilities for the construction of light railways and steam or electric tramroads. It has been alleged in some quarters that the requirements which are imposed by the Board of Trade upon new railways in the interest of the safety of the travelling public and of the railway servants, as well as for the public convenience, may stand in the way of those who are desirous of promoting railways through agricultural or sparsely-populated districts. It has also been urged that light railways may have great utility and importance as a means of assisting those who suffer from the depression in agriculture by affording them easy and inexpensive means of bringing their produce to the best markets. The same observation has been made as regards an even more difficult branch of the subject—namely, the possibility of relieving populous urban districts by giving special opportunities to workpeople to travel in and out of towns at a minimum cost, or by making it easier for manufactories to be established in suburban or country districts. Interest in the movement has, no doubt, been stimulated by the action of those foreign countries in which light railways have been developed. The Board of Trade are sensible of the importance of the question in these various aspects, and have taken great interest in the representations which have from time to time been made to the Department; but they have not yet had before them practical proposals which would enable them to decide how far a demand for economy in construction would justify relaxation of any of their usual requirements now enforced in the interest of safe working, and whether a change in the law by which necessary powers might be more easily or cheaply obtained would be likely to be followed by any considerable development of the modes of transport contemplated. It may no doubt be contended that the powers conferred by the Railways Construction Facilities Act, 1864, as amended by the Railways (Powers and Construction) Acts, 1864, Amendment Act, 1870, and the Regulation of Railways Act, 1868 (Part V.), on the one hand, and the Tramways Act, 1870, on the other, are sufficient to satisfy the requirements of ordinary trading companies desirous of constructing and working light railways or tramroads. The Board of Trade are, however, so much impressed by the desirability of obtaining all the information which can be afforded by persons interested in the movement, that they think it well to take prompt steps for the purpose of eliciting and focussing such views and information; and they conceive that both local authorities and traders, as well as the existing railway companies, will welcome an opportunity of joining in a discussion inaugurated with this object. I am, therefore, directed by the Board of Trade to enquire whether you would be disposed to attend such a conference at the Board of Trade on an early day, with the object of discussing (1) how far the usual requirements of the Board of Trade as to constructing and working new railways may fairly be relaxed, especially in the case of lines built through sparsely-populated and agricultural districts; (2) whether additional legal facilities for obtaining powers to construct tramroads and light railways are necessary or desirable."

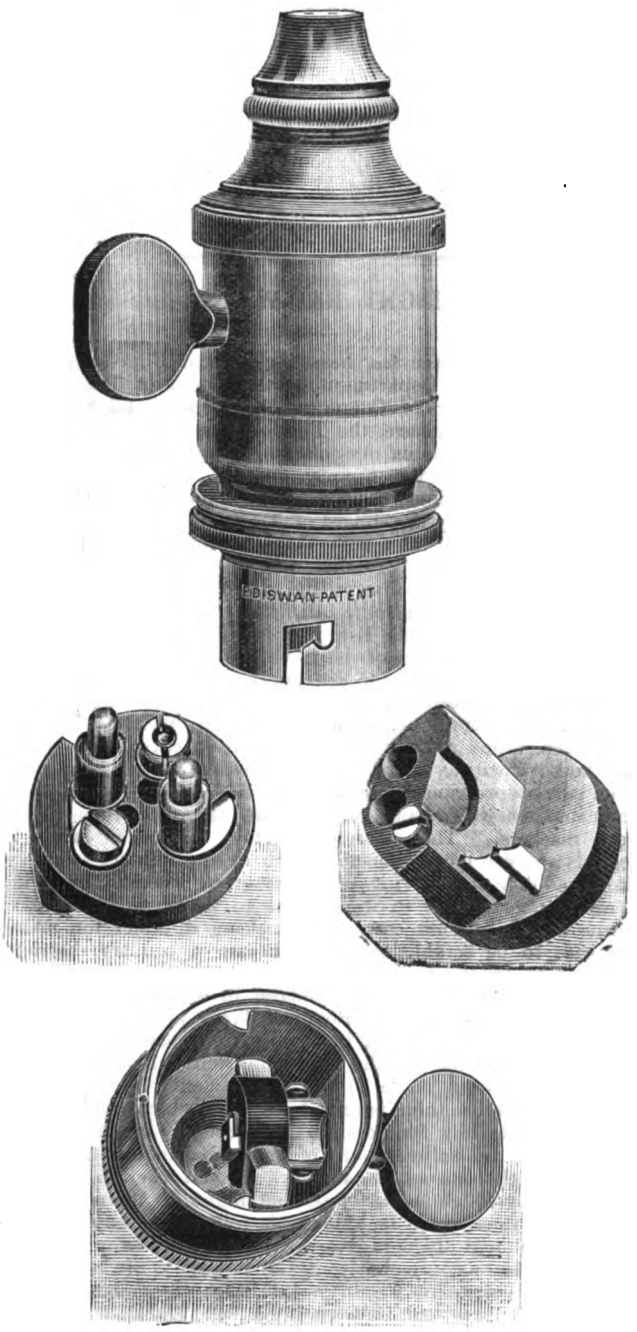
EDISWAN NEW LAMPHOLDER.

The accompanying illustrations represent the Ediswan new lampholder, which is fitted with shade carrier, key, and cord grips. As will be seen from the illustrations, it is easy to wire, and it is naturally claimed by the makers that short-circuits are impossible by the use of this holder, which is made in silver, aluminium, nickel-plated polished brass, black bronze, etc. The illustrations are self-explanatory, and the holder, as will be readily understood, is made by the Edison-Swan United



Electric Light Company, Limited, of 36 and 37, Queen-street, Cheapside, E.C.

CROYDON.

The Croydon County Council had presented to them on Monday night the following recommendation by the General Purposes Committee: "That the Corporation should arrange with some company of undoubted stability to establish an installation for a compulsory area at such contract price as the consulting engineer of the Corporation may approve; that the Corporation should find the necessary capital for the above purpose; that the company should undertake to work the undertaking for a term of years to be agreed, and to maintain the plant in thorough working order, taking the revenue to be derived from the undertaking and satisfactorily guaranteeing to pay to the Corporation interest and sinking fund upon the capital expended; that powers should be reserved to the Corporation to take over the undertaking from the company upon terms to be agreed at an earlier date than the expiry of the period stipulated in the first instance; if the foregoing recommendation be adopted the committee recommend that the sub-committee be authorised to obtain the advice of a consulting engineer, to make all needful enquiries and to report further."

Mr. Alderman D. B. Miller, J.P., the chairman of the committee, in moving the adoption of the report, said the question of electric lighting had exercised the Council for some six years.

Mr. Councillor Martin Luther Moss seconded the motion.

The **Town Clerk** said that some of the councillors seemed to think that the Corporation would have to find the money for working the undertaking, but that was not so.

After some discussion the report of the committee was adopted without a division.

COMPANIES' MEETINGS.

EASTERN EXTENSION TELEGRAPH COMPANY.

A general meeting of the Eastern Extension, Australia, and China Telegraph Company was held at Winchester House on Wednesday, Sir John Pender being in the chair.

The **Chairman**, in moving the adoption of the report, stated that the gross receipts for the half-year under review amounted to £247,681, against £257,986 for the corresponding period of 1893. During the half-year the loss on exchange had been exceptionally heavy, amounting to £21,000; otherwise the revenue would have shown an increase. The loss resulting from the third year of working under the Australian tariff guarantee arrangements amounted to £12,384. During a portion of last year, however, an abnormally large traffic was carried on in connection with the reconstruction of many of the Australian banks. With regard to the proposed Pacific cable, he remarked that it was ripening. The Canadian Government was very anxious to see the scheme carried out. There had been a meeting in Australia and a conference at Ottawa, at which they were all very complimentary to one another; but, so far as he could learn, the result of the conference was to ascertain what would be the best water in which to lay a submarine cable, and afterwards to invite tenders. It was not their business to oppose, but when the cable came to be laid he thought the Government would be wise if it consulted the Company, not only as to where it should be laid, but also as to its maintenance. If it was decided that the cable should be laid, he thought it was likely that that Company would have something to do with it. In any event, they would use the power they possessed to protect their interests. In answer to a letter received from a shareholder, he defended the maintenance of a substantial reserve fund.

The **Marquis of Tweeddale** seconded the motion, which was carried.

MONTEVIDEO TELEPHONE COMPANY.

The annual general meeting of the Montevideo Telephone Company, Limited, was held on Wednesday at the offices, Gresham House, E.C.

Mr. Herbert Ward proposed the adoption of the report and accounts, and said the net profit of the year's working—£6,902—was slightly in excess of the net amount of profit last year. The subscriptions had increased by £460, and the item under this head to the credit of profit and loss was still further augmented this year by the rent received for sub-letting the lower portion of the central premises at Montevideo. He was happy to say that no bad debts had been made during the year, which was an evident effect of the improvement which had at last set in in Uruguay, and which, as it continued, was sure to make itself felt in all branches of trade and enterprise connected with that country. The number of subscribers continued to be well maintained, and showed, in fact, an increase of 46 at the end of July, compared with the same time last year. Altogether, he thought it might fairly be said that the Company was steadily progressing, and with greater activity in business circles in Montevideo would make even greater and more rapid progress. By placing to the reserve £1,000, the position of the Company was further strengthened by the possession of an actually liquid asset to that extent.

The motion was seconded by **Mr. F. W. Jones**, and, after a short discussion, agreed to and a dividend of 4 per cent. on the preference share capital was declared.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Liverpool.—Tenders are invited for putting up 100 (16 c.p.) electric lights and one arc light, with dynamo. Apply to Messrs. Kauffmann, Lawson, and Co., Fox-street, Liverpool.

Sunderland.—The Corporation require tenders for wiring the Town Hall, including the supply and fixing of all cables, casings, switch and fuse boards, lamps, etc. Copy of specification, etc., may be obtained at the office of the borough electrical engineer on the deposit of £1. 1s. Tenders must be delivered at the office of Mr. Fras. M. Bowey, town clerk, not later than November 8.

London, E.C.—Tenders will be shortly invited by the National Telephone Company, Limited, for the following articles. Persons and firms desiring to tender must forward their names and addresses, on or before 5th inst., to the Head Storekeeper,

Digitized by Google

National Telephone Company, Limited, Oxford-court, Cannon-street, London, E.C.: magneto blackboards, trembling bells, magneto driving bands, brass-headed nails, soap, leather bags, chairs, towels, switchboard cords, pitch-pine poles (square), linoleum, creosoted duck boarding, charcoal, Portland cement, slates, glass and emery cloth, beech pole-tops, uniforms, handcarts, roofing felt, composition tubing, tiles, bricks, sand, galvanometers, iron and brass screws (for wood), call signs, raw hide suspenders, sheet lead, sheet zinc, linseed oil, turpentine, French polish, putty, whitening, size, paints, white lead, rope, sash line, mattress twine, tarred canvas, spun yarn, tinman's solder, plumber's solder, glass jars, muriate of ammonia, sulphate of copper, silence call-boxes, methylated spirits, ladders, larch poles, tools, nails, staples, battery-boxes, cast-iron pipes, terminals, tool basses, snatch blocks and double blocks, stationery supplies. Mr. W. E. L. Gaine is general manager.

RESULTS OF TENDERS.

Islington.—Last week the Electric Lighting Committee of the Vestry sat to consider tenders for the erection of an installation on the site acquired by the Vestry, at the west end of Eden-grove, adjoining the Great Northern Railway, at a cost of about £19,000. Of the following tenders, that submitted by Messrs. Macfarlane Bros. was accepted, the price, including glazed bricks, being £22,785. The following are the tenders for the erection of the central station, including extra cost for glazed bricks:

		Extra.
Bush and Sons	£23,360	£1,718
Hall, Beddall, and Co.	24,440	1,710
Harris and Wardrop	23,978	1,790
Higgs and Hill	24,484	1,764
Holloway Bros.	23,210	1,938
Lester and Co	24,731	1,670
Macfarlane Bros	21,685	2,100
Mattock Bros	21,991	1,885
J. T. Messom	22,750	1,700
Perry and Co.	23,229	1,682
Rider and Son	24,996	1,800
L. H. and R. Roberts	23,493	1,896
W. Shepherd	22,500	1,680
G. S. Williams and Sons	22,264	1,917

BUSINESS NOTES.

Wolverhampton.—The new works of Messrs. Thomas Parker and Co. are nearly completed.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,975.

Bristol.—The old King-street Baptist Chapel and Highbury Chapel are to be lighted by electricity.

Stafford.—The new county technical instruction buildings are to be lighted throughout by electricity.

Llanelly.—The Dafen Works have been lighted electrically. The work has been carried out by Messrs. J. C. Howell and Co.

City of London Electric Lighting Company, Limited.—The telegraphic address of this Company is now "Lumen, London."

Thurlstone.—The new woollen mills at Plumpton, Thurlstone, belonging to Messrs. Tomasson and Co., have been lighted by electricity.

Change of Address.—Mr. L. A. Groth, the inventor of the electric tanning system, informs us that he has removed to 88, Neckarstrasse, Stuttgart.

Tonbridge.—New buildings in connection with the Tonbridge School have been opened by the Archbishop of Canterbury. They are lighted by electricity.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 29th ult. amounted to £901, as compared with £583 in the corresponding week of last year.

Derby.—The Duchess of Rutland on Thursday last week opened the new Midland Deaf and Dumb Institution. The electric light has been installed throughout the building by Mr. Edwin Haslam, of the St. Helen's Works.

Change of Telegraphic Address.—Mr. J. Burns, of 15, Long-lane, E.C., the representative of the Delaware Hard Fibre Company, informs us that he has changed his telegraphic address from "Isolateur" to "Isolement."

Altrincham.—The Altrincham Electric Supply, Limited, propose commencing the supply of electric light in the Altrincham and Bowdon districts shortly. The price which will be charged is 8d. per unit, subject to a discount.

Chelmsford.—The Town Council have ordered new electric lamps to be placed in South-road (Barrack-square), Wolsey-road, Railway-square-road, and Seymour-street. All defects in the main cable have now been repaired.

Llanberis.—The survey of the proposed electric railway up Snowdon is rapidly proceeding. The promoters have acquired from Mr. Assheton Smith the lease of the Victoria Hotel, Llanberis, and it is proposed to erect another hotel on the summit.

Gloucester.—The town clerk has reported to the Town Council as to correspondence with certain companies in regard to electric lighting, and stated that both had decided not to apply for a provisional order this year, and had withdrawn their notices.

Wigston Electrical and Engineering Company, Limited.—This Company has been registered with a capital of £25,000 to carry on business as electrical, mechanical, and general engineers, wholesale and retail ironmongers, cycle manufacturers, boiler-makers, etc.

Telephony in Kent.—In a few weeks an exchange will be opened at Sevenoaks and another at Gravesend, while it is proposed at an early date to open exchanges at Sittingbourne, Wateringbury, and Kearsney, all of which will be connected with the trunk lines.

Halifax.—The Town Council have appointed Mr. W. Henwood, of London, foreman of the electric lighting department, at a salary of two guineas per week. It was decided to abandon the negotiations with the vicar of Halifax for an exchange of land adjoining the electric lighting works.

Camberwell.—The Vestry have resolved to inform Messrs. Ellis and Son, of Fenchurch-street, that before they could lay mains for electric lighting on an estate at Red Post-hill they must obtain either parliamentary power or a license from the Board of Trade, and then the Vestry could concur in or dissent from the scheme.

Burnley.—Alderman Lancaster, vice-chairman of the Gas and Electric Lighting Committee of the Town Council, stated at the last meeting of the Council that the use of the electric light was steadily increasing, and in a short time they would have 6,000 8-c.p. lights connected.

City and South London Railway.—The receipts of the Company for the week ended October 28 were £948, against £850 for the corresponding week of 1893, or an increase of £98. The total receipts for the current period of the present half-year amount to £14,811, as against £13,806 in the corresponding period of 1893, an increase of £1,005.

The Foreign Office.—Some of the electric lights went out at the Foreign Office on Monday. This was not due to any failure in the supply of energy from the mains of the Westminster Electric Supply Corporation, but owing to the melting of a safety fuse within the building. The lamps on one floor were out until a new fuse was inserted.

Llangollen.—The members of the Llangollen Bowling Club have played the closing match of the season by the aid of electric light. A further display of the electric light was made in the centre of the town, three arc lights being placed respectively in front of the Royal Hotel, Messrs. Morris and Hughes's, and Mr. P. Davies's establishments.

Bolton.—Wesley Chapel is to be lighted electrically on Sunday next. The work has been carried out by the Corlett Electrical Engineering Company, of Bolton and Wigan. There are over 90 32-c.p. lamps in the chapel, two 50-c.p. lamps in the transept, 67 8-c.p. lamps in the mission-hall below the chapel, besides others in the vestries, lobbies, etc.

Aberdeen.—The question of introducing the electric light into the Municipal Buildings has been considered by the Finance Committee of Aberdeen Town Council. It was remitted to Treasurer Bissit, Mr. Cran (city chamberlain), and Mr. Murray (electric engineer) to procure tenders for the necessary wiring, etc. The cost has been estimated at about £200.

Storage Battery Litigation.—The Electrical Power Storage Company, Limited, write to us as follows: "The Accumulator Company of Philadelphia (the owners in America of the Swan and other patents known as the E.P.S.) have obtained a preliminary injunction issued by Judge Lacombe in the United States courts against the manufacturers of the chloride storage battery in the U.S.A."

Bristol Electric Lamps.—The carriage exhibits of Messrs. Holland and Holland at the Antwerp Exhibition, and which took a *grand prix*, were fitted with the electric light installed by the Bristol Electric Safety Lamp Works, of 63, Queen Victoria-street, E.C. The latter firm inform us that after prolonged experiments the new range-finding instrument devised by Profs. Barr and Stroud are all fitted with their accumulators.

Hull.—The Electric Lighting Committee of the Hull Corporation state that for the quarter ending September 30 they have delivered to consumers 20,149 units, against 10,740 units in the corresponding quarter last year. Their expenditure was £1,927. 8s. 8d., and their income £2,013. 16s. 6d., so that they have a balance of £86 7s. 10d. in hand, and the best quarter to come. They hope by the end of the year to present a very flattering report.

Sunderland.—The Museum and Library Committee of the Town Council have again considered the question of the electric light. An estimate was submitted placing the necessary installation at £314 and the annual cost of the light for the whole building £165. The committee thought it would be better at first to apply the light only to the library and reading-room, and the matter was adjourned till the next meeting to obtain an estimate for that purpose.

Automatic Recording Instruments.—Mr. L. P. Casella, of 147, Holborn-bars, the well-known scientific instrument maker to the Government, has been appointed agent in Great Britain, America, and the Colonies for the sale of the automatically-recording instruments of Messrs. Richard Frères, of Paris, and of which Mr. Casella has just published an interesting catalogue. These instruments can be adapted to all kinds of engineering, electrical, meteorological, and other purposes.

Heckmondwike.—The electric light has been installed in the purifying department of the Heckmondwike Gasworks, the object being to illuminate the shed without the dangers which the use of the ordinary gaslight exposed the place to. The installation is by Messrs. A. Hirst and Sons, Dewsbury, and comprises

Digitized by Google

20 incandescent lamps of 16 c.p. each, though the dynamo is capable of supplying other 30 lights of similar power. It is worked by one of Crossley's 3-h p. gas-engines. The cost of the installation is about £150.

Bootle.—A special meeting of the Town Council has been held in pursuance of the provisions of the Electric Lighting Act, 1882, and it was resolved, upon a motion submitted by Alderman Webster, "That application be made to the Board of Trade, on or before December 21, 1894, for a provisional order under the Electric Lighting Acts, 1882 and 1888, to authorise the mayor, aldermen, and burgesses of the borough of Bootle, in the county of Lancaster, to supply electricity for public and private purposes within the said borough."

Dover.—The arrangements for giving Dover the electric light are being pushed forward. During the past week the hauling in of the cables has been going on, and the transformers are now being put in. The filling up of the station is also being pressed on. With regard to the wiring of premises so as to receive the light, negotiations are going on with owners of house property to put in the fittings and charge the tenants a percentage of the cost in their rent. This is expected to lead to business in cases where the initial cost would have been a hindrance.

Birmingham Central Trams.—A special meeting of the Birmingham Central Tramways Company has been held to discuss a proposition from the directors to reduce the capital from £388,000 to £194,000, in consequence of the heavy burden of unremunerative expenditure in the early years of the company. A fortnight earlier an unsuccessful attempt was made to pass the resolution, but at the last meeting the directors were provided with proxies representing the necessary three-fourths of the company's capital, and the opposition being withdrawn and the proposal carried.

Western and Brazilian Telegraph Company.—At a meeting of the Board of the Western and Brazilian Telegraph Company, Limited, it has been decided that, after placing £2,000 to the reserve fund and £5,000 to the debenture redemption fund, the directors would, subject to audit, recommend at the forthcoming meeting a dividend at the rate of £2 per cent. per annum, free of income tax, for the six months ended June 30 last, carrying forward £5,630. This dividend will be payable as follows: 3s. per share to the ordinary shares, and 3s per share to the preferred ordinary shares. The transfer books will be closed from Tuesday, November 6, to Friday, November 16, both days inclusive.

Bury.—The following report was submitted at the last meeting of the Town Council: "At a meeting of the Electric Lighting Committee on October 17 there were present Alderman Parks (in the chair), Alderman Brierley, Councillors Byrom, Collinge, Hopkinson, and Thornley. Tenders for the central station and other works from five firms were opened, and handed to Mr. Cartwright for tabulation and comparison. The borough engineer submitted his report on the progress at the works. It was resolved that Mr. G. E. Smirk be appointed clerk of works to superintend the erection of the new buildings." Alderman Peel: When may we reasonably expect any result from the Electric Lighting Committee? Shall we have it next year or next year but one? The Mayor: Well, I am not a prophet, or the son of a prophet, but I think some time next year. The minutes were carried.

Appointments Vacant.—The Corporation of Dewsbury invite applications for the following appointments at their electric lighting station—viz., engine-driver, must be a thorough mechanic and accustomed to condensing engines; stoker, accustomed to high-pressure Lancashire boilers and mechanical stokers; dynamo attendant, must have had experience in the running of dynamos; jointer, accustomed to high-class work; and office clerk, who shall also act as meter inspector and keep statement of electric energy consumed; a knowledge of shorthand preferred. Applicants to state age, experience, and wages required. Applications, with not more than three recent testimonials, under sealed cover, endorsed "Electrical Staff," to be in the hands of Mr. E. Mawdesley, town clerk, Town Hall, Dewsbury, by 12 noon on Nov. 3. The Hull Corporation want an improver at their electric light works. Particulars appear in our advertising columns.

Artistic Electric Light Fittings.—A visit paid by one of our representatives to the works of Messrs. S. Haynes and Co, artistic metal workers, of 2, Longford-street, Regent's Park, N.W., afforded ample proof of the company's facilities for manufacturing high-class fittings of a variety of descriptions. Not only do the company produce by their own artists any special designs which any firm in the trade may require, but they also carefully carry out designs prepared by architects. A speciality is made of wrought-iron work, and the standards, pendants, electroliers, and table lamp fittings on view at the works are sufficient to satisfy the most fastidious. The company, in fact, make electric, gas, and oil fittings of every description, and they will, we feel sure, obtain the support and goodwill of the trade. No wiring contracts are undertaken by the company, who have recently supplied to special design fittings for the Baths Club and for the Bishopsgate Foundation Institute.

The Rhondda.—At the fortnightly meeting of the Rhondda Local Board, which has been held at the Public Offices under the presidency of Alderman W. H. Mathias, J.P., a discussion took place upon the proposal by one of the members that the various streets and roads in the valleys now lighted by gas should be illuminated by electric light. Mr. T. Griffiths, M.E., head manager of the Cymmer Collieries, Porth, stated that he was quite prepared to lay an installation at his collieries to generate sufficient electricity to light the whole of Porth and the Cymmer district, as well as the collieries belonging to the company, at a cost not greater than that charged by the gas company. It was agreed that the clerk should write to the other colliery companies asking them if they were prepared to supply the other portions of the valleys. It should be stated that the Cwmparc district, where the Parc and Dare Collieries (Ocean) are situated, is already lighted by electricity generated by a powerful dynamo at the Parc Colliery.

Cardiff.—A special meeting of the Lighting Committee of the Cardiff Corporation was held on Thursday last week, under the chairmanship of Alderman Carey, for the purpose of making a final selection of the candidates for the post of foreman of the electrical machinery at the new electric lighting works. The four candidates who were selected from the applicants for this post were examined by Mr. Massey before the committee as to their experience in central lighting stations. There is a resolution standing on the Council minutes to the effect that all appointments worth £3 per week be opened to the town only. The effect of this resolution was to confine applicants for this post to the town, a thing which Mr. Massey objected to. After some discussion the following resolution was carried: "That in the opinion of the committee the candidates, after having been examined by Mr. Massey in the presence of the committee, do not meet the requirements of the committee, and that the matter be referred back to the Council for instructions."

Newcastle.—A special meeting of the Corporation of Newcastle has resolved to go forward for a provisional order to obtain borrowing powers for laying down cable trams on the Byker, Scotswood, and Westgate sections of the tramways, and to negotiate with the lessees for terms to cover principal and interest. In the course of the discussion, Mr. Morton said that Mr. Alex. Siemens, who advocated the electrical system, called upon the committee and presented a copy of his circular to him (Mr. Morton). Mr. Laws, in his report, had said that the total cost of the system at Budapest was £12,000, whereas Mr. Siemens said the actual cost of construction was one-third of that. He asked Mr. Siemens if he had included the power stations and all the cost that came upon the construction of the line. He now had a letter from Mr. Siemens, in which that gentleman said that they estimated the total cost at £10,000 per mile, though much, of course, depended on the total length and the intended frequency of traffic. According to Alderman Stephens, "electrical science is only in its infancy."

Sheffield.—The Sheffield Electric Light and Power Company, Limited, are extremely busy in supplying lamps and fittings on the premises of new consumers. The progress made during the past year amounts to about 110 per cent. The demand for current has gone up rapidly, so that the company have been obliged to hurriedly obtain additional generating power, and it is expected that a new 300 kilowatt steam alternator, by Mr. Ferranti, will be working on the supply mains by the middle of December next. The new town hall, which is rapidly approaching completion; the Weston Park Museum; Oakbrook, the late residence of the Firth family; and the Church Institute, are among the many orders that the company have in hand for the installation of the electric light. The company is somewhat unique in its method of operation. In addition to holding a provisional order for the supply of current, it, as far as possible, strongly encourages consumers to have their premises wired by the company. They are also contractors in a considerable way for isolated and private installations for residences, collieries, etc.

Chelsea Electricity Supply Company.—The Finance Committee of the London County Council on Tuesday reported: "On January 13, 1888, the late Board granted a license for seven years to the Cadogan Electric Light Company for the erection of a temporary iron smoke-stack at 91, Manor-road, Chelsea, and under the terms of the agreement then entered into the sum of £250 was deposited with the Board to ensure the removal of the stack. On March 9, 1888, the Board at the request of the Company invested the £250 in the purchase of £259. 8s 1d. of Government 2½ per cent. stock, and the dividends received and now in the hands of the Council amount to £17. 7s. 2d. The smoke-stack having been removed, application has been made for a return of the deposit and the dividends accrued thereon, and the solicitor being now satisfied that the secretary of the Company is the person entitled to receive the amount, there appears to be no reason why the money should not be repaid. As the stock now stands in the name of the Council, it is necessary that it should be sold, so that the proceeds may be paid over. We accordingly recommend that the comptroller be instructed to direct the treasurer to sell the sum of £259. 8s. 1d. 2½ per cent. Government stock now standing in the name of the Council, and that the proceeds be paid over by the solicitor to the Chelsea Electricity Supply Company, Limited." This was agreed to.

Islington.—Last week the first step towards making electric lighting in Islington an accomplished fact took place at the corner of Blackstock-road. Operations would have commenced at The Angel, but having regard to the fact that the cattle show and Christmas are approaching, it was thought by the Electric Lighting Committee that excavating and pipe-laying work would seriously inconvenience shopkeepers at the busiest time of the year. It was therefore decided that the laying of the mains should be commenced at Finsbury Park, and after Christmas operations should be commenced at the other extremity of the parish, as within two years the Vestry is compelled to supply electric lighting along the main thoroughfare, stretching from the Archway Tavern and Finsbury Park to The Angel. Amongst those present to witness the cutting of the ground were Messrs. S. Lambert (chairman of the Electric Lighting Committee), D. W. Williams, W. Barratt, J. H. Mote, J. T. Johnson, S.

Digitized by Google

Rayson, A. Walkley, F. T. Bailey, A. J. Fearnhead, T. W. Vine, J. Oldis, Albert Gay (electrical engineer), and G. W. Clarke (chief clerk of the Vestry). Mr. S. Lambert, dislodged a flagstone at the corner of Blackstock-road with a pickaxe, and afterwards dug up a portion of earth. Mr. Johnson went through a similar performance with a shovel, and within a few minutes 20 labourers were busily engaged in digging a trench on either side of the footway in Seven Sisters-road.

Newhaven.—A local paper states that the installation of the electric light at Newhaven, which was inaugurated last week by the London, Brighton, and South Coast Railway Company for their stations, sheds, quays, etc., is now in full swing, and gives the greatest satisfaction. Mr. Smith Mannering, the resident engineer of the hydraulic machinery, has had charge of laying down the generating plant, under the direction of the company's locomotive superintendent, Mr. R. J. Billinton. The engines are of the well-known Willans and Robinson high-speed single pattern, and are supplied with steam from the same boilers that Mr. Billington designed for the hydraulic machinery, thus ensuring a great economy in working, as both plants can be worked at the same time. A notable feature in the engines is an approved application for adjusting the speed to suit whatever load may be on the dynamos, and thus ensure a regular speed, a most important factor in the governing of electric light engines. The dynamos, which are of the Anglo-American Brush type, are each capable of an output of 55 arc lights of 2,000 c.p. The whole of the lighting, including laying the mains and testing, was efficiently carried out by Mr. Cowley and his assistants, under the direction of Mr. E. J. Houghton, the company's electrical engineer. One dynamo is sufficient to meet the present requirements, but a spare set is always ready to start in case of partial failure. Mr. Billinton has put in foundations for a third set, and will no doubt fix the necessary machines as soon as there is a demand for further extension.

Dewsbury.—The report of the Lighting and Water Committee of the Town Council presented to the Council stated that on October 1 a payment of £1,000 was made to Messrs Crompton and Co., Limited, on their contract for engines, etc., at the electric lighting central station, and a second payment of like amount to Messrs. J. and J. Horsfield on account of boilers. Mr. A. Pickersgill, of Dewsbury, was appointed assistant electrical engineer, at the weekly wages of £2, such appointment to commence on the date of the first working of the electric lighting station, and to be terminable by one week's notice, he to devote the whole of his time to the duties of the appointment. On October 15 Mr. Preece, having considered the analysis of beck water, and being of opinion that a cold-well should be constructed outside the condensing-room at the central electric station, it was agreed to build one to hold 25,000 gallons of water. The chairman, vice-chairman, and Councillors Birkhead and Bullock were appointed a sub-committee to engage necessary workmen at the electric light station, also to provide an office for the electrician. On October 22 it was resolved to convert the room in Bradford-road, lately occupied by Mr. Petty, into an office and testing place for the electrician. Amended draft rules by Mr. W. Preece for installation work were approved. A former resolution respecting the construction of the cold-well was rescinded, and the borough surveyor ordered to obtain tenders. Alderman Robinson moved and Councillor Archer seconded the confirmation of these minutes. Councillor Barstow asked if it was the intention of the committee to advertise for workmen or to arrange as to how many to employ for the electric lighting station, and whether the committee were going to confine intending customers for the supply of electric light to any special maker of wire and compel them to purchase from a certain manufacturer of wire. Alderman Robinson, in reply, said that without the men required they could not commence the installation. Men would be selected who were suitable for the work, and they would, of course, have the recommendation of their engineer. They required rules for wiring customers' premises. If they allowed any kind of wire to be used it would be open to abuse. The wire to be used would have to be approved before the lighting could be carried out.

Coventry.—The Electric Light Committee of the City Council are about to issue a circular to householders along the line of route of the electric mains inviting intending consumers to send in their names. It was necessary to state the price at which electrical energy will be supplied. The maximum price authorised is 8d. per Board of Trade unit, and the committee recommended that the price to be charged be fixed at 6d. per Board of Trade unit. At the last meeting of the Council Alderman Hill proposed the adoption of the report, and stated that the 6d. per unit mentioned in the report was equal to about 4s. per 1,000ft. of gas. Of course there were advantages connected with the electric light which might or might not commend themselves to persons. As to the supply outside the line of route, that would depend upon the distances of houses requiring the light and the number that might apply to be connected. He was glad to say that the buildings were progressing very satisfactorily, and that towards the end of January the Corporation would be in a position to supply the light. Mr. James seconded, and Mr. West, in supporting, said he understood that for 6d. the consumers would get sufficient current to work 30 8-c.p. lamps for one hour. Mr. Andrews, as chairman of the Gas Committee, took the opportunity of congratulating the Electric Light Committee on having so far proceeded with the scheme. At the same time, he doubted whether they could afford to supply the light at 6d. per unit and make both ends meet or some profit. It would be very unfair to the gas department if electric light was supplied at a loss, or even without any profit. Both lights should be put on the same footing. If the gas undertaking were expected to yield a profit, so should the electric light. Gas might have been sold at 2s. 5d. per thousand, instead of 2s. 8d. last year, but that the department were expected to produce a profit. He had supposed that the Electric Light Committee would be expected to do the same. Alderman Hill: I may say it is the intention of the Electric Light Committee to play fair. Alderman Tomson was glad to be able to agree with Mr. Andrews on this point, and said it would be a bad way of supporting the Gas Committee if their consumers got a shove off. Mr. Goate asked what the line of route was, and Alderman Hill replied that the information would be given in the circular.

Portsmouth.—Major H. Tulloch, R.E., inspector to the Local Government Board, has held an enquiry at the Town Hall with regard to the application of the Town Council for sanction to borrow £20,000 for electric lighting purposes. Among those present were Alderman G. Ellis, J.P. (chairman of the Electric Lighting Committee), Councillors J. J. Young and Commander W. L. Bamber, R.N., Mr. A. Hellard (town clerk), Mr. Manville (consulting engineer), Mr. Price, and Mr. Johnson. The Town Clerk explained that although sanction was asked to borrow £20,000, the amount immediately required was only £6,000, that sum being needed for the purchase of a new engine and dynamo, and the necessary transformer batteries. Alderman G. Ellis, who explained the matter in greater detail, said that the cost of the engine, dynamo, and fixing would amount to £4,500, and the balance of £1,500 would be required for transformers and the necessary cable connections to the houses. The Inspector: I have noticed that [the electric light is in use in a good many shops, but I was not aware that private houses were taking it up. In reply, Alderman Ellis said that the committee had had a good many applications from houses. The plant, costing £4,500, consisted of a coupled compound engine of 330 h.p., precisely similar to those previously erected, and the balance of the £20,000 would probably be required for more machinery and to extend the electric lighting area. They had already 363 applications from just outside the compulsory area, and if they got 500 such applications they would ask for powers to extend it. They had now actually expended £58,237. 19s. 3d. out of the £60,000 originally sanctioned, and they asked for sanction to take up the balance of about £1,800 for house connections. The cost of house connections amounted on the average to from £8 to £10 per house. They had now in use in shops and houses 5,224 16-c.p. lamps, independent of the street service, and they had besides applications for 1,202 more 16-c.p. lamps within the prescribed area not yet joined up. Of these 182 had come in that morning. Besides these they had an application for supplying the current to a 5-h.p. motor at the technical schools, and an application to supply current for a one man-power motor in a hairdresser's shop. The Inspector said that the progress during the year had been wonderful, and the enquiry was then closed, the inspector afterwards going with Alderman Ellis and other gentlemen to inspect the electric lighting plant.

Salisbury.—A special meeting of the Town Council was held on Friday last to consider the draft form of license applied for by the Salisbury Electric Light and Supply Company, Limited, as approved by the Board of Trade. The Town Clerk laid before the Council the draft form of the license, as approved by the Board of Trade, and Mr. Hammond's report upon it. He read this report, from which it appeared that the principal alterations made by the Board of Trade were the reduction of the period of duration of the license from seven years to two, and the reduction of the maximum price of electricity per Board of Trade unit from 9d. to 8d. The report also drew attention to the fact that the amending clauses which it had been suggested should be inserted in the license had been rendered unnecessary by the clause which limited the duration of the license to two years instead of seven. The Town Clerk said that the object of the special meeting was to give the Council an opportunity of offering any objections to the amended form of the license. Mr. Watson asked whether, supposing the company did not apply for the provisional order, and did not carry out the works proposed, the Council would have any remedy against them for the expense and trouble they had been put to? The Town Clerk said he should think not. The Mayor said the company had spent a considerable sum of money already, showing that they were in earnest. Mr. Horder said he supposed the carrying out of the proposed works depended upon the shares being taken up by the public. What Mr. Watson meant was, supposing the public did not take up the shares, would the Council have any remedy. The Town Clerk: The company have given an undertaking to apply for a provisional order, but they will not move until they get this license. Mr. Fullford said that naturally the company would not begin the work until the license was sanctioned and in their hands. Mr. Horder: Not until the public have taken up the shares. Mr. Watson asked what guarantee they had that the company, which was at present unpersonal, would carry out the work? The Town Clerk: None. Mr. Brittan remarked that the chief part of the expense the Council had incurred was £50 for Mr. Hammond's services. The Mayor said that although some people thought there had not been a great deal done for £50, the information and knowledge they had gained would be of great use to them later on. In reply to Mr. Watson, the Town Clerk said if the company did not get a provisional order within two years of the commencement of the license the whole scheme would be at an end, and any works which they had constructed would be valueless to them. Alderman Brown proposed, and Mr. Fullford seconded, a motion to the effect that the Council had no objections to offer to the amended form of the license. This was carried.

Worcester.—The Electrical Exhibition Sub-Committee of the Town Council have presented a balance-sheet showing that the total receipts in connection with the recent exhibition amounted to £212, and the expenditure left a credit balance of £49. 6s. 10½d., without using the grant of £50 made by the Council's resolution of July 3 last. The admission receipts amounted to £133. 14s. 9d. The Mayor, in moving the adoption of the balance-sheet, spoke of the educational value of the exhibition. Mr. Cock pointed out that Mr. Davenport was paid £21 as secretary to the exhibition. The Mayor replied that Mr. Davenport undertook the whole responsibility of organising the exhibition. He placed himself in correspondence with all the firms who exhibited, and made himself responsible, at very great labour, to keep the exhibition in order. He thought the thanks of the committee were due to Mr. Davenport for the admirable way in which he carried the exhibition through. Mr. Chaplin endorsed the Mayor's remarks, and said he thought Mr. Davenport must have had an enormous amount of work to have brought the exhibition to so successful an issue. Alderman Hill seconded the adoption of the balance-sheet, and said he believed the exhibition had been not only a source of great gratification to everyone who attended it, but that if there had been no profit at all, they would have received a great deal of profit in the advertisement which the exhibition had given to the electric light, and in promoting applications for installation. The proposition was agreed to. A letter was received from the secretary of the tramways company, asking the committee to reconsider the tram by-laws, as they proposed to introduce a modern light car for 13 passengers, to be drawn by one horse. The Mayor remarked that in reconsidering the by-laws they might suggest to the company that the cars should be run by electricity. The matter was referred to the sub-committee. An application was received from Messrs. McKenzie and Holland asking that the current should be supplied to the Vulcan Works from 5 a.m. The Mayor stated that the committee were in a position to authorise the manager-in-charge to put on the current from five o'clock in the morning until 12 at night, and he proposed that this should be done. He had no doubt that in a fortnight they would be able to have a continuous current during the 24 hours. Although they opened the generating station on October 11, the entire work throughout the city was not completed, and the high-tension main had had to be interfered with for various purposes. They would also have the street lamps alight within the time he had mentioned. If they could have a continuous current for the 24 hours by the end of the first week in November they would have achieved a great success. The proposition to turn on the current from 5 a.m. to 12 p.m. was agreed to, and certain lamps are to be dispensed with at the end of November.

Liverpool.—Mr. Charles Reltie writes to the *Liverpool Echo* as follows: "The Liverpool Municipality know they will have to adopt electric light sooner or later, but evidently they mean to make us wait as long as ever they can. The idea, 'considering the great improvements being made in the electric light, they would not lay out any money at present." Now, sir, my opinion is that the electric light is at its highest state of efficiency, and is only waiting for people to take it up, and the only room for improvement is in small details. The cost of electricity for supply purposes has been worked out by many men of authority to be about 3d. per unit. The Liverpool Supply Company charge 7½d. But they rightly take into account first cost and heavy expenditure of laying down mains and plant. But I would guarantee if they had not the monopoly of Liverpool plenty of companies would be glad to supply the current for 4d. per unit, and then would be making 25 per cent. profit. It would not mind so much if the Municipality, or whoever has the public lighting in their hands, were more thoughtful. We as contractors would get more work, and be able to give others work, as being better for themselves and keeping pace with the times. The electric light should be used in all public buildings and thoroughfares supposing it cost treble the price of gas. What is the good of cheap gas if it is not effective? London now has the electric light, as many know, and is admitted, even by the Americans, to be the finest lit city in the world. All the gas poles have been taken down as they were obstruction. Gas consumes enough air in one hour to keep five men. If it were only for that one reason the electric light ought to be used at any cost; but as it happens (if you use your own engine, as would be the case if St. George's Hall and other buildings were lighted up) it can be produced for about a third less than gas, as well as having all the advantages over gas." At a meeting of the subscribers to the school ship "Conway," held in Liverpool, Mr. Charles McIvor stated that the installation of the electric light throughout the ship had cost £600. The committee felt that the "Conway" must advance with the time, and they were also conscious of the competition with the sister ship on the Thames, the "Worcester." The electric light was an advantage which would be most highly valued, and it had been provided at a cost which was considerably less than the cost to the "Worcester." Alderman Smith, at the last meeting of the Town Council, alluded to the motion down in his name in favour of authorising the Watch Committee to enter into negotiations with the Liverpool Electric Lighting Company for the purchase by the Corporation of their undertaking at an early date. He asked the Council to refer the motion to the Watch Committee, without expressing any opinion whatever upon it. Mr. Miles seconded this proposition. Mr. Houlding thought the Health Committee should have something to say upon the question of electric lighting. Alderman Smith agreed that the question should also be placed before the Health Committee. After further discussion it was decided that the question of the position of the electric light company with the Corporation of Liverpool should be placed before the committee mentioned for their consideration and report.

Edinburgh.—A West-end correspondent writes asking over what area in the city the streets are to be lighted by electricity, as he says that while the electric mains are being laid down in many thoroughfares he sees no arrangements made for street-lighting. The streets which are to be lighted by the Corporation by electricity are Leith-street, from Theatre Royal to Princes-street; Princes-street, Maitland-street, westwards to Haymarket; Lothian-road, Earl Grey-street, Tollcross, Home-street, Leven-street, to Barclay Church; Fountainbridge, from Earl Grey-street westward; Queensferry-street and continuation to Dean Bridge; North and South Bridges, Nicholson-street, Clerk-street, South Clerk-street, to Hope Park-terrace; Waverley Bridge and Cockburn-street; High-street, from George IV. Bridge to Holyrood; George IV. Bridge, Lindsay-place, Greyfriars-place, and Forrest-road. Three lamps are to be placed in front of the Science and Art Museum, Chambers-street, and possibly the back of the Castle may be lighted. The other streets where mains are being put down are within the compulsory area formed for the private lighting of houses, shops, offices, etc. The new Craig House Asylum for the Insane, which was opened on Friday last by the Duke and Duchess of Buccleuch, is lighted by electricity, the work having been carried out by Messrs. Ernest Scott and Co., of Newcastle. Mr. Bryson was the consulting electrical engineer. At Tuesday's meeting of the Town Council, Mr. Mackenzie asked Mr. Williams on what authority he said at his ward meeting "that owing to the electric light contracts being above the estimates, the first part of the work was not properly done. No provision was made (Mr. Williams said) in the way of water-tanks, so that when the ground subsided, as it certainly would, the pitch points would crack, and moisture would percolate into the conduits, with the risk of combustion and perhaps serious accident, as had happened in America." Mr. Williams said that the report was correct, with the exception that he prefaced the statement with the words that "he had heard it stated." But if the convener could assure him that means had been taken to prevent the water from getting to the wires, he would be, and he was sure the public would be, perfectly satisfied. Mr. Mackenzie said he had written Prof. Kennedy, who wrote him as follows: "The paragraph you sent me in a newspaper cutting is absolutely untrue. On the contrary, all the contracts have come very well within the estimates. Indeed, although there have been very great extensions made in the scheme since my estimate was sent in, I believe they will very slightly exceed the estimate for the smaller quantity of work exclusive of the station. The sentences about the water-tanks are perfectly unintelligible to me. There has been no trouble in the matter, and no alteration whatever from the original scheme as designed." At a later stage, Mr. Mackenzie said he was sorry they were not quite so far on with the electric light as they had expected. They had 20 miles of road works laid and had now only three to lay; and if nothing came in the way they would be in a position to turn on the current about the beginning or middle of March.

New Swindon.—At the last meeting of the General Purposes Committee of the Local Board, it was resolved that Mr. J. G. W. Aldridge, of 9, Victoria-street, Westminster, be the electrical engineer for the purpose of the provisional order, and that the clerk arrange the fee to be paid for his services. It was also resolved that the necessary notice to be given applying for a provisional order for electric lighting should include every street within the district, and also all public buildings belonging to the Board. Mr. Jones, at the last meeting of the Local Board, took exception to this report, and moved as an amendment to the committee's recommendation that the said committee reconsider the question of obtaining this provisional order. He objected to the whole area being included, because the scheme as previously laid before the Board only applied to this Board's district and certain streets therein. The present proposal would be a very large item financially, and he for one would like to know something of the cost before the members of the Board committed themselves. Moreover, he thought that at the present stage the idea of electric light was too premature. The surveyor would tell the members that there were 20 miles of streets in the district, and if the provisional order was to include the whole of that, then a large expenditure must necessarily be involved. He thought the whole matter should go back to the committee for further consideration, and then be more clearly laid before the Board. He was aware that the clerk would say that all the necessary formalities had to be carried out early next month, but even supposing the Board did not insert the necessary advertisements in the local newspapers in November, no private company could come into the town and fix a plant for electric light without the Board saying yea or nay to it. He considered that the new authority, to be elected by the vote of the electorate, should say whether this new light should be adopted. Personally, he should welcome it, but as the Local Board would soon go out of office they should not hand over to the new body a great responsibility in which that new body had no voice. The Clerk pointed out that it was necessary to carry out these formalities, but that did not bind the Board to carry out all the details. Mr. Mills: It does not follow that because we name all the streets that we shall light them all. The Clerk: No; certainly not. Mr. Longland contended that there was no time now for the Board to reconsider this matter if they wished to obtain the provisional order this year. Mr. Jones had been talking about placing a responsibility on the new authority, but so far as he could understand the matter the only responsibility they would place upon the new Urban District Council would be the cost of obtaining the provisional order and the plans. It would then be

Digitized by Google

in the hands of the new authority to throw the matter over or otherwise. This Board, by doing what was now recommended, would be simply securing a position for the new authority. It seemed to him a rather doubtful question whether if the Board took no action in the matter they would be able to keep out a private company. The Clerk said the proposed action would give the new body who were to succeed the Board power to proceed. Mr. Protheroe expressed surprise that Mr. Jones should raise his opposition now, when he readily acquiesced in the matter at the General Purposes Committee meeting. He (Mr. Protheroe) thought the Board would act very wisely in adopting the recommendation. Mr. Jones: I say the scheme is in a crude state, and we have not had the full details brought before the Board. Mr. Mills wished to say that Mr. Jones was making an incorrect statement, because the Board had had the report of the Electrical Committee before them, and fully discussed it. Mr. Jones: I agree that we have had figures put before us, but we have not had the advice of the electrician. The matter is too premature. Mr. Jones's proposition did not find a seconder, and the committee's report was adopted.

Ealing.—The Electric Lighting Committee have reported to the Local Board that they had had before them a memorial from residents in the Mount Park district asking for the electric light mains to be laid in that district, with the view to the introduction of private lighting into their residences. The committee recommended that all applicants for the electric light be asked to fill up the necessary form of application, when the matter could be brought formally before the Board for further consideration. The committee recommended the adoption of a similar course as to the Drayton Court shops, in respect of which a memorial had also been received. The memorial from Spring Bridge was ordered by the committee to stand over for further consideration. The Surveyor, reporting on the scheme, mentioned that application had already been made for 2,500 private lamps (half the number estimated for). The cause of the flickering experienced in the light at present was that the machinery had not sufficient "load" on; as the supply was increased that defect would disappear. Mr. St. John, in reference to the application that had been made for an extension of the electric light mains to the northern part of the district (Haven Green, Woodville-road and vicinity), urged that, if practicable, the Board should for the present discontinue the laying of the electric cable along the Uxbridge-road, from the foot of Hanger-lane to the Acton boundary, and use the cable that would have been employed between those points for the introduction of the light over the railway into the Haven Green district. The Clerk, in reference to the legal difficulties that might be encountered in carrying out Mr. St. John's suggestion, said that, apart from that Board, there would be three parties whose consent would be necessary to the alteration proposed being made—the contractors, the Board of Trade, and the Local Government Board. He did not apprehend that the contractors would raise any objection in the matter, and he also did not think that any difficulty which could not be surmounted would emanate from the Board of Trade or from the Local Government Board with regard to the proposal (having regard to the fact that the portion of the Uxbridge-road, the electric lighting of which would under this proposal be temporarily abandoned, was included in the area of compulsory supply as defined in the electric lighting order obtained by the Board from the Board of Trade, and in the loan consent to the borrowing of which had been granted by the Local Government Board). The Board, the clerk added, could not legally make the alteration without the consent of the Board of Trade and of the Local Government Board. To do so would be a breach of faith towards those bodies, and the Board could not legally apply, without the consent of the Local Government Board, money which had been borrowed for the provision of electric lighting in one part of the district to the provision of that lighting in another part. The Surveyor, in reply to a question, said that the length of the road thus proposed to be left unlighted electrically was about 1,000ft. He added, in reply to a further question, that it would, of course, be practicable for the Board to order the engineers or contractors to cease the laying of the mains at the point indicated—the foot of Hanger-lane. He would point out, however, in regard to the proposal, that although the portion of road, the electric lighting of which it was proposed to abandon for the present, contained but few houses, the Ealing Common Station of the District Railway was included in it, and there was considerable traffic along the road to and from that station. The District Railway Company were also large ratepayers in the district, and they might, of course, have something to say with reference to this suggested deviation from the plans sanctioned by the Board of Trade and the Local Government Board. After some further discussion, Mr. St. John formally moved: "That the engineers be directed to stop the work of laying the electric cable along the Uxbridge-road from the bottom of Hanger-lane to the Acton boundary until the next meeting of the Board. That formal notice be given of the intention to discuss at that meeting a proposition to temporarily abandon the laying of the electric mains along that part of the Uxbridge-road, with a view to utilising for the introduction of the electric light into the northern part of the district the cable that would otherwise have been used in that part of the Uxbridge-road, such notice to be placed on the agenda paper for the next meeting of the Board; and that in the meantime the clerk communicate with the Local Government Board and the Board of Trade with the object of ascertaining whether they would be prepared to consent to this contemplated temporary diversion (for the reasons mentioned) from the original plans for the laying of the electric mains." Mr. Kasner seconded the proposition, on the ground that he was anxious that the Board should not apply for any additional loan at present, and because, while application for any additional loan would in his opinion be objectionable, the Board were desirous of meeting as far as possible the wishes of the residents for the supply of electric light into private premises in the district. The proposition was carried, a remark being made that if the Local Government Board and the Board of Trade refused consent to the proposed deviation, no expense would have been incurred, and the Board would simply be in the position they were in at present in regard to extending the electrical lighting of the Uxbridge-road to the Acton boundary. On the suggestion of the Surveyor, and on the proposition of Mr. Kasner, the Board unanimously passed a cordial vote of thanks to the firms, the assistants, and others who had worked in connection with the recent electrical exhibition, and had helped to make that exhibition the success it had been. Mr. Kasner, in moving the proposition, observed that the members of the Board were all delighted at the success that had attended the exhibition, and certainly thanks were in a special measure due to those exhibitors from outside the district who at considerable expense had fitted up stalls at the exhibition.

Kingston-on-Thames. — The minutes of the Lighting and Market Committee of the Town Council contained the following items: "Resolved that the borough electrical engineer be authorised to draw up a circular letter to all persons on the circuits where the electric cable is being laid, calling their attention to the benefit to be derived by using the electric light. The borough electrical engineer was instructed to report at the next meeting the probable cost of laying mains for charging electric launches. The borough electrical engineer reported that a letter had been received from Mr. W. H. Preece, engineer-in-chief to the General Post Office, enquiring on what terms the Corporation would supply current to the post office at Kingston. The further consideration of the matter was adjourned to the next meeting. The chairman reported that the floor at the electric light station was in an imperfect condition. Resolved that the borough surveyor be instructed to report at the next meeting as to the cost of laying down block flooring. The consulting engineer reported that a new boiler was necessary at the electric works. Resolved that the same be ordered from Messrs. Belliss and Co., similar to the previous boiler, but with certain modifications. The consulting engineer handed in a certificate for £2,000 to Messrs. Siemens—viz., £1,000 on account of work under their contract, and £1,000 for general work. Resolved that such certificate be passed on to the Finance Committee with a recommendation for payment by the Council. A letter was read from Messrs. Siemens with regard to the arc lamps, in which they said: 'With the view of showing our confidence in the cables already laid, we are prepared to extend the guarantee we have given under our contract for 12 months, and until the expiration of this period we will make good, free of expense to the Corporation, faults which may show themselves in these cables, and which are clearly traceable to defects in the cables themselves.' Resolved that the Council be recommended to make application to the Local Government Board for permission to borrow a further sum of £4,000, and that the necessary steps be taken so that the enquiry may extend to the above-mentioned sum as well as to the £6,000 already applied for." At the meeting of the Town Council when this report was brought up, Councillor Collings moved that application be made to the Local Government Board for sanction to borrow an additional £4,000 for electric lighting. He said the Council had already sanctioned an application for £6,000 which the Local Government Board had not yet dealt with, and the committee found that the £6,000 would not be sufficient to enable them to carry out the works that would be necessary during a comparatively short period. They therefore thought it far better to have one enquiry for £10,000, which would carry on the work for some time. The committee did not anticipate that it would be necessary to borrow anything like that extra £4,000 at present, nor would they take it up without coming to the Council for permission to do so. But in consequence of the increased demand for the electric current the present machinery was quite insufficient to provide all that was necessary, and even the £6,000 already authorised by the Council to be borrowed would not be enough to provide for all the expenditure which would be necessary within a very limited time. They wanted at least £2,000 more to pay for extensions of mains which were in prospect at a very early date, and for a new boiler which had been ordered, subject of course to the approval of the Local Government Board to the borrowing of the money. They anticipated that further extensions would be necessary within a very short time which would take up another £1,000, leaving a balance of £1,000, which would probably not be expended for 18 months or two years. It was impossible to forecast exactly what money would be required, but as the undertaking grew and the number of consumers increased, extension would be necessary, and the cost must be met. He spent some time that morning in going through the figures, which he thought might be of interest to the Council. The original contract of Messrs. Siemens was £11,800, buildings and architect's commission cost £4,500, extras on Messrs. Siemens's contract £600, wiring and lighting the central station £80, meters and testing instruments £300, small extensions of mains £460, connections for customers £160, engineer's commission £650, making the total original outlay £18,550. The extensions, many of which had already been ordered, and which the £6,000 was intended to cover, were: new engine and alteration £1,450, gas-engine and alteration £450, foundations for engines £100, connection to the gas-engine £25, spare machinery £225, customers' connections £300, extension of mains, arc lighting lanterns, etc., £400 and meters £500. This brought the total expenditure up to £22,000, which was the amount which the Council had at present consented to borrow. What they really wanted to expend beyond that amount was £800 for a new boiler, £100 for setting it, £500 for further transformers and a sub-station which would shortly be necessary at the

Digitized by Google

other end of Thames-street, £250 for a new workshop and tools, £1,000 for further low-pressure mains and meters, and £350 for contingencies. This would bring the total up to £25,000, and would leave £1,000 in hand for working capital, or to be devoted to further expenditure as customers increased. Councillor Walker seconded the motion, and said they were all aware that as business increased so must the capital outlay. He thought this application was a very good sign of increasing business, and he hoped the Council would see it in that light, and not imagine that because the committee were asking for more money they would be running the Corporation into debt. He believed that before long the electric lighting business would be a paying concern. For the first two or three years there must be a certain amount of loss, but he was sure that eventually it would be a good thing for the Corporation. They were continually receiving fresh applications for the current, and it was the right thing to go on. Councillor Wellbelove: Is the new boiler necessary to replace an old one that is worn out, or is it an additional one? Councillor Collings: An additional one. The motion was carried *nem. con.* Councillor Collings said at the last meeting something was said about the arc lighting cables possibly having to be taken up. The Council would see from Messrs. Siemens's letter that they had perfect confidence in their cables, and had extended their guarantee for another year.

PROVISIONAL PATENTS, 1894.

OCTOBER 22.

20105. **Improvements in electric measuring instruments.** Benjamin Davies, University College, Liverpool.

20127. **Improved porous pot for primary batteries.** Michael Martin Bair, 7, Carteret-street, Queen Anne's-gate, London.

20152. **Improvements in incandescent electric lamps.** Vincent Fabris, 64, Mark-lane, London.

20170. **Improvements in electrical soldering and welding apparatus.** Hugo Zerener, 46, Lincoln's-inn-fields, London.

OCTOBER 23.

20223. **Improvements in electrically-worked pumps.** Robert Luke Howard, 77, Chancery-lane, London.

20241. **Improvements in alternating-current motors.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Edward Andrews Clark, United States.) (Complete specification.)

20259. **Improvements in electrolytic apparatus for decomposing metallic salts.** Carl Kellner, 46, Lincoln's-inn-fields, London.

OCTOBER 24.

20293. **Improvements in holders for globes or shades of electric, gas, or other lamps.** George Frederick Sanders, 36, Temple-street, Birmingham.

20317. **Improvements in electric glow lamps.** Joseph Robert Mally, 18, Fulham-place, Paddington, London.

20330. **Improvements in electromagnetic machines.** Ignaz Vago, 70, Wellington-street, Glasgow. (Complete specification.)

20354. **Improvements in and connected with the electro-deposition of aluminium and aluminium alloys.** Pascal Marino, 33, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, May 31, 1894, being the date of application in France.)

20363. **Improvements in rests or supports used with telephones for supporting the arms or elbows of persons using the telephones.** Henry Gilbert and Alfred Brawn Gilbert, 7, Staple-inn, London.

20366. **Apparatus for applying electricity to regulate and control engines or machinery.** Ludwig Epstein, 28, Southampton-buildings, Chancery-lane, London.

20382. **Improvements in electric telephones and means of signalling thereon.** Alfred Charles Brown and George Richard Neilson, 50, Old Broad-street, London.

OCTOBER 25.

20397. **An improvement for cutting out electric arc lamps.** Henry James Creffield, 3, St. Fidelis-road, Erith, Kent.

20432. **An improved electric bell for mines and outdoor use generally, with damp-proof or hermetically sealed contact breaker.** Frederick Charles Allsopp, 165, Queen Victoria street, London.

20439. **Improvements in the production of electrical energy and in means or apparatus employed therein.** Henry Tipping, Henry Ashur Tobias, William Henry Cadman, and Richard Joseph Crowley, 55, Chancery-lane, London.

20442. **Improvements in and connected with arc electric lamps.** James Eglinton Anderson Gwynne and Rankin Kennedy, 11, Furnival-street, Holborn, London.

20462. **Improvements in and connected with induced current telegraphy.** Frank Eustace Wilkins Bowen, 6, Bream's-buildings, Chancery-lane, London.

OCTOBER 26.

20482. **Improvements in junction couplings or clips for electric lighting installation.** Hahnemann Adolphus Cutmore, 172, Queen Victoria-street, London.

OCTOBER 27.

20546. **Improvements in electric telegraph systems for working double current translation.** Samuel Butcher, 47, Lincoln's-inn-fields, London.

20548. **Improvements in electrical motor fittings for transmitting motion to light machinery.** Henry Lea, 18, Southampton-buildings, Chancery-lane, London.

20561. **Improvements in electric arc lamps.** George William Lowcock, 70, Market-street, Manchester.

20595. **Improvements in electrical signalling devices for railways.** Walter Grimes, 323, High Holborn, London.

20596. **Improvements in or connected with electric accumulators.** Siegfried Hammacher, 6, Lord-street, Liverpool. (Complete specification.)

20613. **Improvements in electric relays.** Charles Langdon-Davies, 24, Southampton-buildings, Chancery-lane, London.

20614. **Improvements in or connected with electric heating wires or coils.** Friedrich Wilhelm Schindler, 433, Strand, London.

SPECIFICATIONS PUBLISHED.

1891.

5461. **Overhead system of electric traction.** Dickinson. (Second edition.)

1893.

19251. **Electric indicator for colliery engine-houses, etc.** Crawshaw and Battye.

20384. **Electricity meters.** Hookham.

20847. **Carbon brushes, blocks, etc., for electric generators and motors.** Scott.

20975. **Voltaic batteries.** Gregg.

22856. **Printing telegraphs.** Fowden.

23477. **Electrical signalling on railways.** Orme.

23478. **Electrolytic preparation of oxygen, etc.** Coehn.

1894.

16408. **Printing telegraphs.** Fowden.

NOTES.

Telephony in Germany.—Telephonic communication has been established between Berlin and Dortmund.

Gas-Engine Competition.—A competition between gas-engines is now taking place in France, more particularly between the Charon and the Crossley motors.

Laundry Exhibition.—Electricity as applied to ironing machines, etc., is being demonstrated at this exhibition, now being held at the Agricultural Hall, Islington, N.

Telegraphing Through Space.—The Allgemeine Elektricitäts-Gesellschaft have been experimenting in telegraphing through space between Wansee and Neu-Cladow on the Havel, a distance of about 2¾ miles.

Electric Lighting Powers.—In Paris the duration of concessions for electric lighting is 18 years. Evidently the French are more content with shorter powers than the English, or they would have adopted our Electric Lighting Act of 1888.

Electric Traction in Austria-Hungary.—A preliminary concession has been granted by the Austrian Ministry of Commerce to Mr. Wenzel Formanek for an electric tramway from Königgrätz railway station to Freihofen.

Electric Traction in Switzerland.—At the close of 1893 there were nine electric lines in Switzerland—namely, at Orbe-Chavorney, Grütschalf-Mürren, Sissach-Gelterkinden, Bürgenstock, San Salvatore, Stanserhorn, Vevey-Montreux, Zürich. and Stannsstaad.

Electric Lighting in Algeria.—Messrs. Gally and Viette have taken over the electric light installation at Batna, and will instal a 50-h.p. Laval steam-turbine. M. Dalloz is erecting a central station at Bougil, where he will employ Boulet steam-engines and Desroziers dynamos.

The Telegraph in British North Borneo.—The British North Borneo Company has communicated to Reuter's Agency the following telegram respecting the progress of the telegraph line across North Borneo: "Eastern section trial trace, 117 miles; permanent 24ft. trace, 32 miles."

Royal Institution of Great Britain.—The general monthly meeting of this institution was held on Monday, Sir James Crichton-Browne, treasurer and vice-president, occupying the chair. Mr. Arthur Salvin Bowlby, Sir Charles Cameron, M.P., Baroness de Knoop, and Lord Romilly were elected members.

Madras Electric Tramway.—The company carrying out this undertaking have obtained an equitable extension of time, owing to a circumstance over which they had control. The "consideration of route" in the city of magnificent distances is still occupying attention, and forms the subject of municipal discussion.

Battersea Polytechnic.—Mr. Joseph Harwood (the secretary) announces that this institution is attracting an increasing number of students. The total number of entries for day and evening schools and classes is 3,607, as against 2,816 in the first quarter of last session, these entries being represented by about 2,520 individual students.

Electric Cranes in France. — The Bordeaux Chamber of Commerce have been considering the advisability of the introduction of electric cranes on the quays, and offers have been received from the Compagnie Française pour l'Exploitation des Procédés Thomson-Houston, Messrs. Guilton and Bertolus, of St.-Etienne, and Messrs. Lombard, Gérin, et Cie.

Institution of Junior Engineers.—Mr. Alexander Siemens has accepted the presidency of this institution (formerly the Junior Engineering Society) for session 1894-5, in succession to Mr. J. Wolfe Barry, vice-president, Institution of Civil Engineers, and will deliver his presidential address on Friday evening, 16th inst., at the Westminster Palace Hotel.

Institution of Civil Engineers.—The first meeting of the ensuing session of the Institution of Civil Engineers will be held on the 13th inst. in the existing theatre of the society, to which a temporary access has been arranged from the old entrance in Great George-street. The library, reading-room, and offices are at present located at No. 9 on the other side of the street.

Central Telegraph Office Library.— On Friday evening last a promenade concert took place at the Holborn Town Hall, with the double object of celebrating the opening of the extended premises for the Central Telegraph Office Library, now capable of containing 10,000 volumes, and of aiding the funds for further increasing the number of works of a scientific and philosophical character.

Northern Society of Electrical Engineers.—This society will meet at the Palatine Hotel, Hunt's Bank, Manchester, on Monday evenings, November 12, December 10 (annual general meeting), January 14, February 11, March 11, April 8, and May 13. The second annual dinner of the society will be held on Friday, January 11. At next Monday's meeting a paper will be read by Mr. H. Henderson on "Lighting Installations."

Telephony in India.—The use of the telephone in India increased considerably during the year. There are now 1,360 subscribers and 1,380 exchange connections of the telephone companies at Calcutta, Madras, Bombay, Karachi, Rangoon, and Moulmein, besides 26 exchanges and 205 exchange connections under the control of the Telegraph Department. The new telephonic apparatus introduced last year is stated to be an unqualified success.

Ohm's Law.—One of the directors of an electric railway company, the *Electrical World* says, enquired of one of the electrical engineers of the road the meaning of $C = \frac{E}{R}$, which he saw around so much, and on being told that it stood for capital $= \frac{\text{earnings}}{\text{receipts}}$, he replied that he thought it was a capital joke.

Personal.—Dr. W. E. Sumpner, of London, has been appointed principal of the new technical school, Birmingham, at a salary of £500 per annum. Dr. Sumpner is a doctor of science, and has been connected with the movement inaugurated by the City and Guilds of London for the advancement of technical education. In 1887 he was appointed a demonstrator and lecturer at the Central Training College, and last year went to the Battersea Polytechnic, being elected head of the physical and electrical departments.

New Books.—We have received from Messrs. Whittaker and Co. "Electric Light Installations," by Sir David Salomons, Bart., B.A., seventh edition, revised and enlarged, of which vol. 1 deals with "The Management of Accumulators," vol. 2 with "Apparatus," and vol. 3 with "Application." Messrs. Whittaker also send us the second edition of "Electric Lighting and Power Distribution," by Mr. W. Perren Maycock. From Messrs. S. W. Partridge and Co. we have received "Electricians and their Marvels," by Mr. Walter Jerrold.

Hampstead Central Station.—Before a meeting on Saturday last, at the Hampstead central station, of the Association of Municipal and County Engineers, Mr. W. H. Preece, F.R.S., read a paper describing the station. The author mentioned that the undertaking was started four

Digitized by Google

weeks ago with 2,176 8-c.p. lamps fixed, that 1,218 had since been added, and that applications were in hand for a further 4,475 lamps, or a total of 7,869 lamps. Mr. Preece expressed the opinion that the station was going to be financially a great success.

Electrically-Controlled Clocks.—A scheme is at present under the consideration of Glasgow Town Council Bazaar Committee for the establishment throughout the city of a system of standard time, by means of electrically-controlled public clocks regulated every second from the observatory clock. Prof. Becker has been consulted, and has informed the committee that it would be easy to connect 20 clocks from the observatory, these in turn controlling a certain number each, and in the case of the street dials, both working and regulating. The system is intended to include private house time-keeping.

Borough Polytechnic.—Sir Bernhard Samuelson, at the distribution of prizes last week at this institution, referring to the increase of scientific and technical education in this country, said that at the present time there were already 150 technical and science schools throughout the provinces, and between 70 and 80 in course of erection. In London there were eight or nine polytechnics, but not one fifth of the workers, in proportion to those in other big towns, such as Liverpool and Bradford, received scientific and technical education. He urged the students to be not only skilful, but versatile, and adapt themselves readily to industrial changes.

Society of Arts.—The arrangements for the one-hundred and forty-first session of the Society of Arts are now announced. It commences on November 21 with an address from the chairman of the council, Major-General Sir John Donnelly. The first regular paper of the new session will be by Mr. Hiram Maxim on his "Experiments in Aeronautics," and this will be followed the succeeding week by one by M. Hermite on "The Electrical Treatment of Sewage." Six courses of Cantor lectures are promised, of which the first is by Prof. Vivian Lewes on "Explosives." There will be, as usual, a course of juvenile lectures after Christmas; the lecture this year is by Prof. Vernon Boys, his subject being "Waves and Ripples."

New Mains in London.—Sanction has been given by the London County Council to the Westminster Electric Supply Corporation to lay mains in Carington-street; to the House-to-House Electric Light Supply Company for mains in Courtfield-road; to the St. James's and Pall Mall Electric Light Company for mains in Argyll-place, Foubert's-place, and across Carnaby-street; and to the Notting Hill Electric Lighting Company for mains in Pembridge-villas. Objection has been taken to transformer-chambers proposed to be constructed by the London Electric Supply Corporation in Burlington-gardens, and by the County of London and Brush Provincial Electric Lighting Company in Wandsworth, Putney, and Pentonville.

Electric Traction in Italy.—The Municipal Council of Milan has extended the time during which the Società Edison is permitted to experiment with electric traction, which has been tested for some months on the Sempione line by that company. The Edison Company and the Società Anonima degli Omnibus are negotiating with a view to an agreement being arrived at concerning large traction schemes. If the proposed agreement is carried out, *L'Elettricità* says that it is probable a large transmission project, embodying some 22,000 h.p., at Paderno sull' Adda, will be brought into use. A scheme has been presented to the Municipal Council of Palermo by Signor Ferrando with a view to the construction of a complete system of electric tramways in that town.

Electric Lighting in Burmah.—An Indian paper remarks: "The lighting of the new Government House at Rangoon—a *pucca*, red brick edifice, which will replace the present wooden structure—the Gymkhana Club, the lunatic asylum, and the gaol with electricity has been claiming the serious consideration of the Government of Burmah. The machinery and dynamos will be placed in the Rangoon gaol. But the public are anxious to know why the town cannot be lighted up in like manner, Mr. D. D. Coath, an experienced engineer, having offered to replace each of the present street oil lamps by an electric light at the same cost as the public are now paying for street-lighting. This offer was made three years ago; but the Municipality cavil at giving Mr. Coath a monopoly for 10 years."

Electric Traction in Germany.—It has been decided that in future as regards Berlin the conversion of light railways into electric lines will not be decided by the President of Royal Police alone without consultation with the Municipality, but by both in conjunction. It is expected that this will lead to good results by avoiding friction. The Allgemeine Elektricitäts-Gesellschaft, of Berlin, will construct an electric tramway at Elbing. The official inspection has taken place of the Bochum-Herne electric tramway. The line is about four miles in length, and the overhead trolley system is employed, the return being by the rails. A speed of 18 miles an hour can be attained. The plant at the power station comprises two tubular boilers, two Kuhn compound engines, and two Siemens dynamos with overset armatures.

Electric Lighting in Austria-Hungary.—The Municipality of Graz are considering the advisability of lighting both the municipal theatres electrically. A meeting has been held at Budapest of the Ungarische Elektricitäts-Aktiengesellschaft, at which Mr. Béla Fischer, the chairman of the company, reported on the first year's business of the Budapest central station. On October 12 there were 48 miles of cable laid, and there were 668 consumers, using an equivalent to 32,451 normal incandescent lamps. There were 685 arc lamps connected, and 37 electric motors of a total of 58 h.p. Tenders have been received from the Budapest Allgemeine Elektricitäts-Gesellschaft and from the Ungarishe Elektricitäts-Gesellschaft for the electric lighting of the general meeting hall in the new Town Hall. The tender of the former company, being the lower, has been recommended for acceptance.

Electric Lighting in France.—The Alais Gas Company having declined to make use of the privilege of adopting any new mode of lighting as laid down in its agreement with the town, the local authorities have given a concession for electric lighting to Messrs. Louche, Bonnefoi, and Froment. The Café de la Paix, Angers, is to be lighted electrically, the local gas company supplying a gas-engine for the motive power. The little town of Courthezon, Vaucluse, is to be lighted by electricity, a concession having been granted to Mr. L. Warnecke, of Lyons. Water power will be used. A small central station has been opened by Mr. Dutertre at Ivry-la-Bataille, Eure. Both water and steam power are employed. Rechniewski dynamos and Dujardin accumulators are installed here. At Lille, Messrs. Thierry and Sigraud, confectioners, have started a private electric light installation, using Crossley engines and Sautter dynamos.

Proposed Acton Electric Railway.—At the invitation of the London United Tramways, Limited, a large party started yesterday for Havre in order to inspect the admirable electric trolley-wire system of tramway lines now operated in that town. The party consisted of members of the Hammersmith and Acton local authorities, and the

Digitized by Google

visit has been undertaken by them to see just exactly what may be done in the way of electric traction with overhead wires. The Havre lines, it will be remembered, were equipped this year by the French Thomson-Houston Company, and they rank without exception as the best in the country for excellence of design and good workmanship. There need be little fear but that the members of the party will come back from their short journey so impressed with the advantages of this method that they will welcome gladly the proposal to operate the Acton tramway in a similar fashion.

Royal Society.—The following is a list of those who have been recommended by the president and council of the Royal Society for election into the council for the year 1895 at the anniversary meeting on November 30: President, Lord Kelvin, D.C.L., LL.D.; treasurer, Sir John Evans, K.C.B., D.C.L., LL.D.; secretaries, Prof. Michael Foster, M.A., M.D., Lord Rayleigh, M.A., D.C.L.; foreign secretary, Sir Joseph Lister, Bart., F.R.C.S.; other members of the council, Andrew Ainslie Common, LL.D, William Crookes, F.C.S., Francis Darwin, M.A., Andrew Russell Forsyth, Sc.D., Sir Douglas Galton, K.C.B., Prof. Alexander Henry Green, M.A., Sir John Kirk, K.C.B., Prof. Horace Lamb, M.A., Prof. Edwin Ray Lankester, M.A., Prof. Alexander Macalister, M.D., Prof. John Henry Poynting, D.Sc., Prof. Arthur William Rücker, M.A., Osbert Salvin, M.A., Prof. J. S. Burdon Sanderson, M.D., Thomas Edward Thorpe, Sc.D., and William Henry White, C.B.

Lectures.—Mr. Hall, president of the Carlisle Microscopical Society, has delivered an address to the members on "The Electric Light in Use with the Microscope," and having shown the advantages of the light over other lights in expanding microscopical slides, making use of a four-cell Pitkin accumulator for the purpose, he referred to the question of introducing the electric light into Carlisle. He said that we had excellent gaslight, and it was being continuously improved, but electric light was also wanted because it was the purest and the best light. On Tuesday last Prof. A. W. Rücker delivered a lecture at Victoria Hall, Waterloo Bridge-road, on "The Electric Spark." A paper was recently read by Mr. H. B. Edwards, A.I.E.E., of Wakefield, before the members of the Derbyshire Metallurgical and Engineering Association, at Codnor Park, Derbyshire, in which special reference was made to the pumping and electric lighting plant just completed by him at the Pollington Colliery, belonging to Messrs. Jas. Oakes and Co., Alfreton Low Works. Prof. A. C. Chattock has read a paper, entitled "The Electricity of Water," before the Bristol Naturalists' Society. A paper on "The Electric Light" has been read by Mr. Cozens before the Taunton Literary Society.

The Proposed Pacific Cable.—A *Times* telegram from Ottawa, dated 1st inst., says: "Mail advices received by the Hon. Mackenzie Bowell to-day give a more encouraging account of Messrs. Fleming and Mercer's mission to Hawaii to secure a landing-place for the proposed Pacific cable than had been previously announced. Mr. Fleming says the Hawaiian Government is profoundly impressed with the importance of the scheme, and if the consent of the United States Government can be procured Hawaii will lease Neckar Island or Bird Island to Great Britain for cable purposes, and will give a subsidy of £7,000 sterling annually. Mr. Fleming says that a very favourable understanding has been established with Hawaii. Mr. Mercer will soon be proceeding to Washington." A Reuter's telegram of the same date says: "The Hon. Mackenzie Bowell, Canadian Minister of Trade and Commerce, has received a large number of offers for the construction of the proposed Pacific cable. Tenders will be opened in a few days." A Reuter's telegram from Winnipeg, dated 5th inst., stated that Messrs. Sandford Fleming and Mercer, the commissioners who have recently been in Honolulu endeavouring to secure Neckar Island as a landing-place for the Pacific cable, have returned. Mr. Fleming expresses the belief that his mission will prove successful.

Conference of Science Teachers.—A largely-attended conference of the organised science teachers and teachers of secondary schools receiving aid from the Science and Art Department was held at South Kensington Museum last week. Dr. Forsyth, of Leeds, presided. Captain D. W. Abney and Mr. C. A. Buckmaster, one of her Majesty's inspectors of science classes, represented the South Kensington Department, and Mr. Yoxall represented the National Union of Elementary Teachers. It was pointed out that the continuity of secondary schools must be based on some system of co-ordination with our elementary system of education. One speaker suggested that if the middle classes could get rid of the prejudice they had with reference to the Board schools, the secondary education difficulty would be solved. Another proposed that secondary education should be given only by properly trained teachers, and should be given either gratuitously or at merely nominal fees. Objection was incidentally taken to the appointment of inspectors who had not been practical teachers. Mr. Buckmaster said he had been a science teacher for several years before his appointment, and that three of the recently appointed inspectors had previously distinguished themselves as science teachers It was agreed to embody the spirit of the meeting in the form of resolutions to be forwarded to the Education Department.

British Insulated Wire Company's Cables.—In its issue of October 20, *To-Day*, in referring to the temporary extinction in the supply of light in the City, said that "it might be well if some disinterested person would enquire from the City of London Electric Lighting Company why their cables have so rapidly worn out." The paragraph went on to refer to a rumour that when the City of London Company called for tenders for their cable supply "the tender made by one of the oldest and best of the cable companies was passed over in favour of that of a much smaller company asking a considerably higher figure," and that "now these cables have so signally failed the older company has been called in to repair and make good their former rival's faulty work." In this connection we have been asked by the British Insulated Wire Company, Limited, of Prescot, to draw attention to the retraction contained in *To-Day* of November 3. The latter says: "We have no hesitation in expressing our regret that the paragraph in question appeared in our columns. We thought that the standing and knowledge of our informant warranted the acceptance of his statement, but by some means or other he was misled, and in turn misled us. The error has given the British Insulated Wire Company just cause of complaint, but recognising our good faith in the matter they have made their representations in the spirit of courtesy we gladly recognise, and which makes it doubly incumbent upon us to give this explanation, and to say how much we regret the mistake made by our informant."

Steam Condensation.—M. Ch. Compère recently brought before the Société des Ingénieurs Civils de France the results of a series of experiments which he has made at the Creusot works in regard to the quantity of water necessary for steam condensation. These results show generally that when engineers are limited in the use of water, condensing plant can be adopted without sensibly

Digitized by Google

diminishing the economy of the steam-engines. The tests were made with a Corliss engine of the type first constructed at Creusot. The quantity of water injected into the condenser was ascertained by a Samain meter, and the temperature was determined by causing the water to flow from a tap placed closed to the inlet of the meter. The temperature of the hot water from the condenser was taken directly in the delivery pipe of the condenser. Indicator diagrams were taken on the engine, so as to get to know the work, and consequently the consumption of steam per indicated horse-power. It having been impossible to provide a special boiler to supply the engine, the consumption of steam by the latter was established by the calorimetric method, based on the increase in temperature of the weight of water passed into the condenser. Diagrams were also taken on the air-pump. From the result of the experiments, it was found that as the injected water was at 10deg. C., the expense of this water can be reduced by half by condensing at 40deg. C., instead of at 25deg. C., without the consumption of steam per horse-power much increasing, being only from 7·4 to 8 kilogrammes. This conclusion, as M. Compère says, is very interesting in cases where one is compelled to pay a high price for water, or when it is necessary to sink a well and lay down a pump.

Physical Society.—A meeting was held in the rooms of the Chemical Society, Burlington House, on the 26th ult., Prof. A. W. Rücker, F.R.S., president, in the chair. In opening the proceedings, the President said the occasion might be regarded as another sign that the boundary between chemistry and physics was breaking down. On behalf of the council he tendered the thanks of the Physical Society to the Chemical Society for the use of the rooms. Prof. H. E. Armstrong, president of the Chemical Society, said his council offered a cordial welcome to the Physical Society. The change, he thought, would prove of much greater importance than a mere removal. Now that the childhood of the Physical Society was passed, its manhood involved new responsibilities, and great opportunities for good now presented themselves. The Physical Society of London ought now to become the head centre of physics in the United Kingdom. He (Dr. Armstrong) was pleased to learn that the society had undertaken the preparation and publication of abstracts of physical papers appearing in foreign periodicals, and said the matter was of such great importance that it should be done thoroughly. In a work of such a magnitude he regarded the co-operation of other societies, such as the Institution of Electrical Engineers, as absolutely necessary. The President, in acknowledging the welcome, said the Physical Society was extremely obliged to the president and council of the Chemical Society for the great benefits conferred. Dr. Armstrong's advice to go ahead would not be forgotten. He then announced that at future meetings tea would be provided for members at 4.30. The exhibition of a voltameter by Mr. Naber was postponed. Mr. E. H. Griffiths, M.A., read a paper on "The Influence of Temperature on the Specific Heat of Aniline."

Light Railways and Tramways.—As we duly announced in last week's issue, an important meeting of the Engineering, Electrical, and Allied Trades Sections of the London Chamber of Commerce was summoned for the afternoon of Friday, the 2nd inst., and at the time appointed a considerable number of the most prominent members had assembled to discuss the question of better facilities for the development and working of light railways and tramways consequent upon the recently-issued circular from the Board of Trade. Mr. Crompton was voted to the chair, and the discussion at once opened. Mr. Pauling advocated strongly the extension of narrow-gauge lines under more favourable conditions than had hitherto existed, and instanced the results obtained in South America especially as reasons for greater development. Mr. Bolling spoke briefly upon the importance of cheap construction obtained by using the ordinary roads for track laying, with consequent limitation of speeds: and his remarks were of great practical value, coming as they did from an acknowledged authority upon light railway matters in general. Mr. Jeremiah Head gave an abstract of his recent experience in the United States respecting the standardising of railway gauges and the enormous increase of electric tramways operated on the overhead wire or trolley system, concluding with an expression of hope that similar progress might be made in this country during the next few years. The speakers followed at great length, each one expressing the most hearty approval of the movement now initiated: and, finally, Major Flood-Page offered a formal resolution thanking the Board of Trade for their action in the matter, and promising cordial assistance in every possible way. This was adopted with approbation, and Mr. Garcke then proposed a resolution appointing a small committee of eight or nine gentlemen (being members of one section or the other) to elect two delegates for attending the Board of Trade conference, and to decide upon the course of action which the delegates should follow at the conference. Powers were given to the committee to add to their number, and with a vote of thanks to the chairman the meeting then terminated.

Electrically-Operated Centrifugal Machines.—In an illustrated circular which has reached us from the Allgemeine Elektricitäts-Gesellschaft, of Berlin, it is pointed that, owing to their intermittent working and high speed, centrifugal machines are advantageously adapted for being direct driven by electric motors. Continuous current motors, it is submitted, are impracticable for this kind of work, as owing to the vibrations of the shaft of the centrifugal machine the motors can scarcely be run without sparking, whilst at the same time difficulty is experienced in the constant supervision of and attention to the commutator and brushes. With a view to overcome these disadvantages, the Allgemeine Gesellschaft have brought out a rotary-current motor which has neither commutator nor brushes. This motor, it is claimed, fulfils all the conditions required for safe and suitable centrifugal working. It keeps its speed in a higher degree than a direct-current motor, since its number of revolutions only changes in accordance with an alteration in the speed of the steam-engine driving the generator, so that care has only to be taken for its proper regulation. Moreover, a rotary-current motor is able to run with a much greater overload than a corresponding direct-current motor. This is absolutely necessary with centrifugal machines when large masses have to be set in motion, and this advantage is obtained by a special construction of the armature. If the installation, as is mostly the case, consist of a large number of centrifugal machines, and when one motor is thrown in, the others and the countershafting work with it and support it. The centrifugal rotary-current motors made by the company in question are in sizes ranging from 1 h.p. to 5 h.p., and at speeds varying from 1,000 to 500 revolutions. The motor is arranged under and on the same vertical shaft as the revolving drum, various modifications being made for different circumstances. Among the applications already made of this type of motor for driving centrifugal machines may be mentioned their use in textile factories and sugar works. In one case alone no less than 91 motors of about 490 h.p. have been installed in a sugarworks.

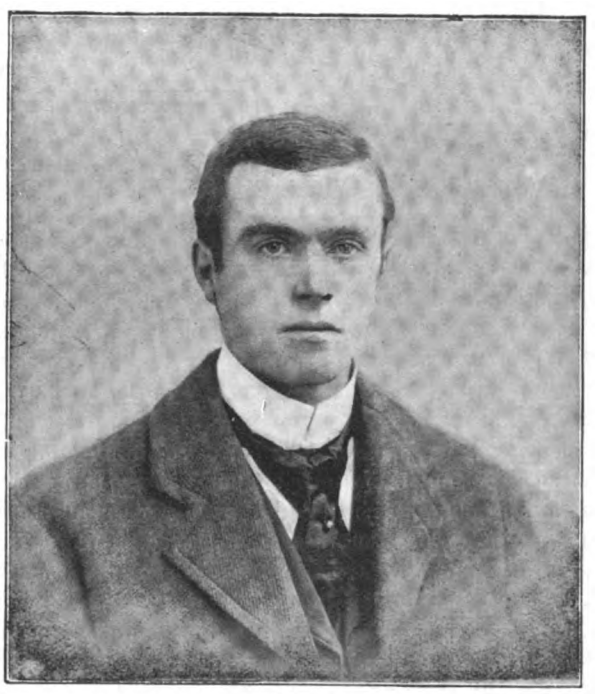
THE ELECTRICITY WORKS AT SOUTHPORT.

General Remarks.

Of the well-known watering places on the west coast of Lancashire, Southport justly occupies a prominent position. It is not only a delightful town in summer, but as the climate is extremely mild and salubrious, the town has become a most desirable and frequented winter resort. Cleanliness and dryness are also characteristics of the town, and even after a heavy storm the streets rapidly dry. The town, it will doubtless be remembered, is situated on the sandy shores of the estuaries of the Mersey and the Ribble. It is possible to see from the Promenade the opposite bank of the Ribble, almost as far as Preston, including Lytham, Ansdell, and St. Annes. Blackpool is out of sight, but its Eiffel Tower is observable.

A sandy shore faces the Promenade, and next comes a deep-water channel, the fringe of which is touched by the end of the pier. This channel is backed by the Horsebank,



ARTHUR ELLIS, A.M.I.E.E.
Electrical Engineer to the Southport Corporation

with the Irish Sea in the rear. At low water this sandbank hides the sea from the Promenade. Thus it has sometimes been said that Southport is a seaside resort without the sea.

Southport is not an ancient town. In fact, a wilderness of sandhills formed the site of the present Southport just over a century ago, when William Sutton, of Churchtown, established an inn in the locality. Time passed away until 1840, when the population had risen to some 700 persons. In 1867 the town was made a municipal borough, and since then its progress under the energetic administration of the Corporation has been rapid. The borough now covers a superficial area of 7,526 acres, and the population is about 50,000. The Promenade already referred to is a handsome carriage-drive, some 2½ miles long, fronting the sea, and the pier jutting out from it is approximately a mile in length.

The main thoroughfare is Lord-street, which is one of the finest streets in the world. The principal entrance to the Winter Gardens is situated in this street, as are also the Town Hall and Public Buildings, of which a photograph is annexed. There are two tramway companies affording a public service, botanical gardens, aquarium, and winter gardens, and other places of amusement, parks, etc.

The group of buildings shown in the photograph comprises the Town Hall (which is on the extreme left), the Cambridge Hall, the Science and Art School, and the Atkinson Free Library and Art Gallery. As will be seen, the frontages are rendered more attractive by a handsome fountain. Although erected as long ago as 1853, the Town Hall underwent certain alterations and improvements in 1887, which transformed the building so as to meet the present requirements of the Municipal Council. The town, thanks to Mr. Wm. Crabtree, M.I.C.E. (the borough surveyor), is provided with modern sanitary arrangements, and one of the most noticeable features of many of the dwelling-houses, especially those lying in the suburbs, is that they are semi-detached. The town clerk is Mr. J. Davies Williams, and the members of the Gas and Electricity Committee are :

ALDERMAN JAMES WOOD, Mayor.
ALDERMAN HACKING, Chairman.
COUNCILLOR HESFORD, Vice-Chairman.
COUNCILLORS :

AUSTERFIELD.	ISHERWOOD.
BAXTER.	PILLING.

Southport Public Buildings.

Preliminary Steps in Electric Lighting.

The gasworks, which are located at Crowlands, some 2½ miles distant from the Town Hall in Lord-street, are the property of the Municipal Council. The charge is 3s. per thousand in Southport for lighting purposes, and 3s. 3d. in Birkdale, a discount of 5 per cent. being allowed if the accounts are paid within one month from the end of the quarter. It is also at Crowlands, on spare land adjoining the gasworks, that the municipal electricity works have been erected.

When the subject of electric lighting was first brought forward a few years ago, the Town Council as a body did not think it advisable to establish a municipal supply of the electric light; but the fact gradually became impressed upon the minds of the members that if they did not take any steps in this direction a company would do so. Consequently wiser counsel prevailed, and the Municipality resolved in 1892 to lay down plant and furnish a supply to those who wished to have the electric light. Naturally the first point to decide after obtaining a provisional order was as to what electrical system should be introduced. A report by Mr. George Wilkinson, M.I.E.E., the consulting engineer to the Corporation, was subsequently submitted, giving comparative estimates of the capital expenditure

Digitized by Google

that would be required for carrying out a low-pressure system and a high-pressure system respectively.

The Adopted System.

After due consideration, it was eventually decided to supply the town or compulsory area with the electric light, laying down at Crowlands a high-pressure alternating-current system of generation, and a low-pressure system of distribution to consumers from transformer sub-stations arranged in the centre of the town. Plans and specifications were accordingly prepared by Mr. Wilkinson, and tenders were invited for the erection of the buildings for the accommodation of the steam and electrical plant, and for the supply of the machinery and accessories. In the meantime application was made to the Local Government Board for permission to borrow £28,000 for the purpose of establishing electricity works. An enquiry into the matter having been held by an inspector of the Local Government Board, sanction to the scheme and loan was subsequently given by that Department.

There is no doubt, from the scattered nature of the town and from prospective extensions of the supply of electric light outside the compulsory area, the Town Council were fully justified in adopting the high-pressure alternating-current system; but it seems a pity that the works have been erected so far as 2½ miles from the immediate supply area. Even taking into consideration the lighting of the whole of the town and suburbs—a rather unlikely matter—a more central or, at all events, an intermediate position for the site of the generating station would have been preferable; and for that matter there appears to have been sites available nearer the town than the gasworks at Crowlands. Nevertheless, the Corporation have the consolation of knowing that the support accorded by the public to the new undertaking which is being inaugurated to-day is such that it may compensate for any disadvantages of the distant site and the drop in the current pressure due thereto.

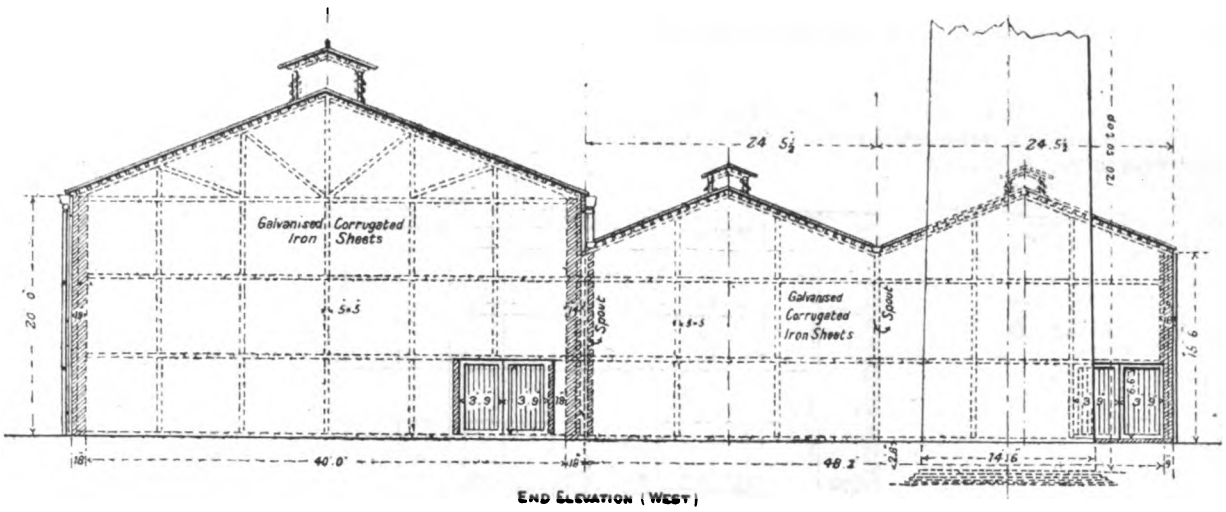
The tenders having been received and examined, contracts were entered into as follow for the erection of the buildings and the provision of the machinery and accessories enumerated:

Southport Electricity Works.—Map showing Site of Generating Station, the positions of the cables being indicated by the dotted lines.

Station buildings	Thomas Bridge, jun., Liverpool.
Boilers and steam-pipes	Oldham Boiler Company, Oldham.
Engines	Browett, Lindley, and Co., Limited, Patricroft, Manchester.
Electrical plant and switchboard.	Mather and Platt, Limited, Manchester.
Pump	Tangyes, Limited, Birmingham.
Heater	Patent Heater Condenser Company, Westminster.
High-pressure cables	British Insulated Wire Company, Limited, Prescot.
Low-pressure mains and transformers.	Siemens Bros. and Co., Limited.

Digitized by Google

The work of constructing the generating station buildings, on land adjoining the gasworks, was shortly afterwards commenced, Mr. Arthur Ellis, A.I.E.E., being appointed clerk of the works. A sudden attack of illness, however, compelled Mr. Wilkinson to leave Southport shortly after the beginning of the undertaking. Mr. Ellis then took up the work, and was appointed electrical engineer seven months ago. He made certain alterations and modifications in the original plans, and he has supervised the execution of the whole of the work, bringing the station to its present successful position. Proceeding now to describe the electricity works, we first come to—

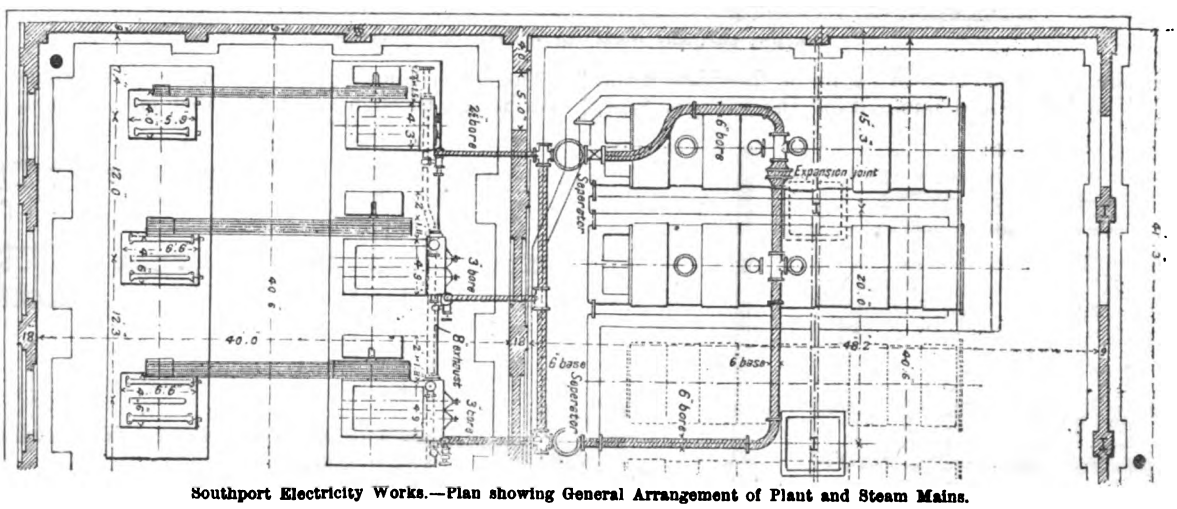


END ELEVATION (WEST)

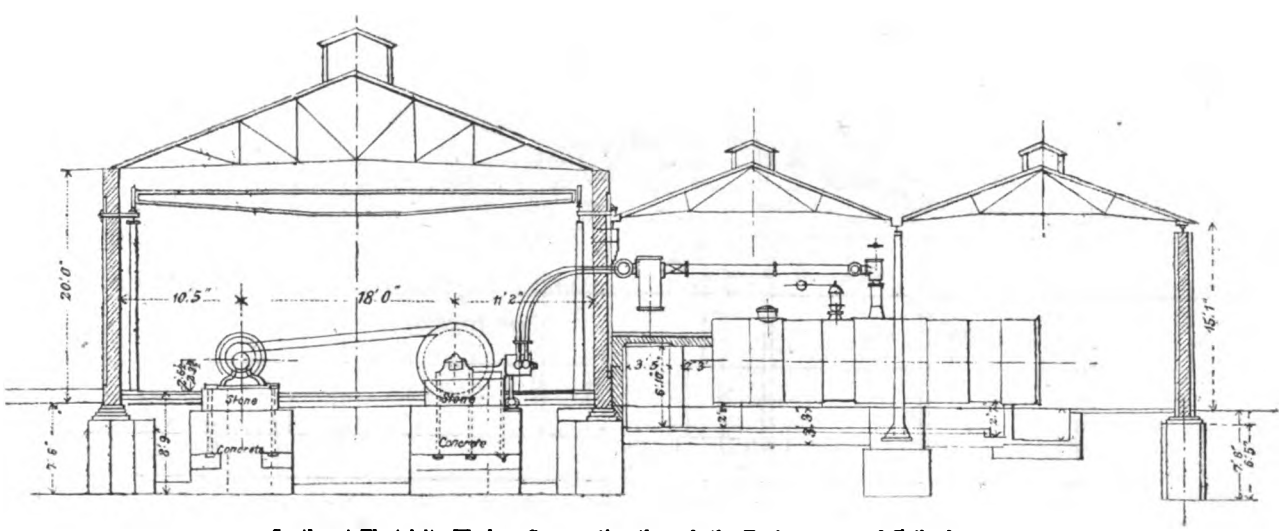
Southport Electricity Works.—End Elevation of Station Buildings.

The Boiler-House.

The boiler-house, which is 40ft. by 48ft. 6in., contains two Lancashire steel boilers, 28ft. long by 7ft. in diameter, constructed for a working pressure of 125lb., and supplied by the Oldham Boiler Works Company, of Oldham. The boilers have been designed so that small fuel may be used for firing.



Southport Electricity Works.—Plan showing General Arrangement of Plant and Steam Mains.

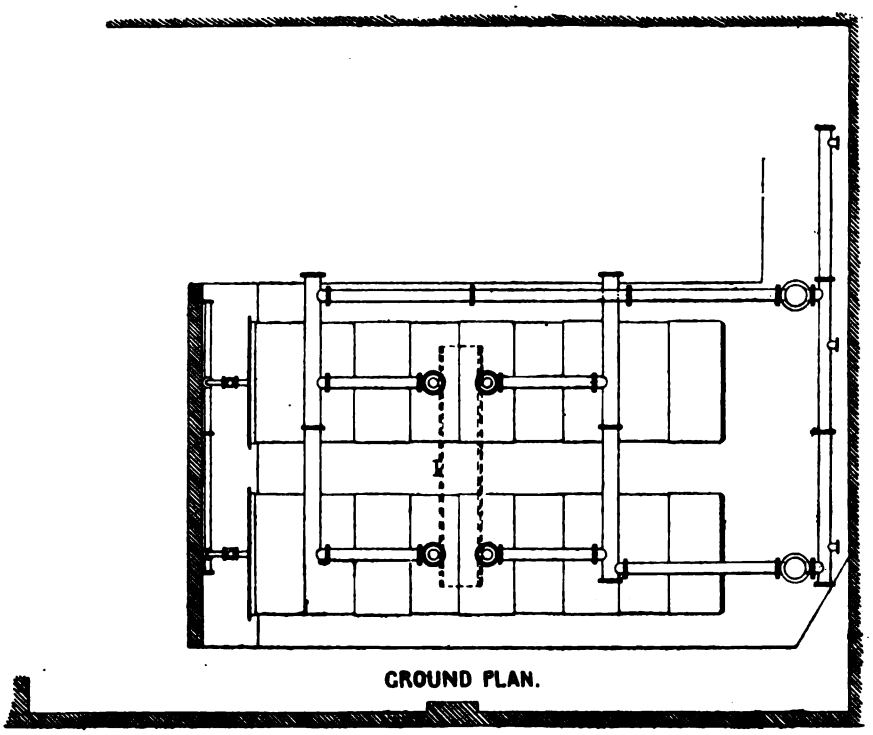


Southport Electricity Works.—Cross-section through the Engine-room and Boiler-house.

Each boiler is provided with two feed back-pressure valves, one being arranged on each side of the end plate so as to provide for a duplicate feed service. A dead-weight safety-valve and a second safety-valve arranged to blow off

Digitized by Google

either at low water or high steam, are also fitted to each boiler. In addition to these, two junction valves 6in. in diameter are arranged to provide for a duplicate steam service. The boiler feed pump is of the Tangyes type, geared to a small vertical engine, and carried on a common bedplate. The main steam-pipe is of wrought iron, and is arranged in the form of a ring carried through the wall of the boiler-house into the engine-room, and provided with duplicate branches to the engines, so that any section may be disconnected as may be desired.



Southport Electricity Works.—Ground Plan of Boiler-house.

The boiler-house is equipped with an improved Berryman heater, through which is passed most of the exhaust steam from the engines for the purpose of heating the feed water for supplying the boilers. This heater, which has been provided by the Patent Heater Condenser Company, of 16, Great George street, London, S.W., is of the com-

pany's No. 7 type. It is capable of raising the temperature of 500 gallons of feed water per hour up to 208deg. by means of the exhaust steam only. The heater has been made extra strong for a working pressure of 120lb. per square inch. The heater is 13ft. 3in. high, and 2ft. 6in. square at the base. The casing is wrought iron, and measures 21in. diameter. The exhaust steam inlet and outlet are 7in. in diameter, and the water inlet and outlets are 3in. in diameter. The heater is fitted with the new

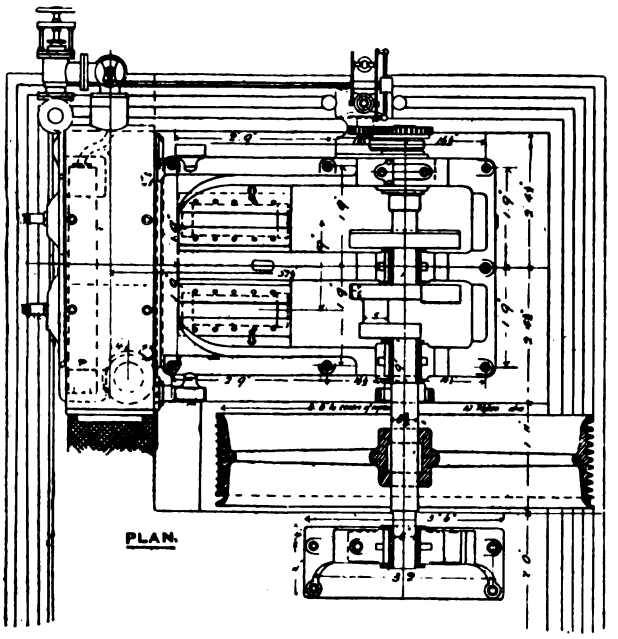
Southport Electricity Works.—Berryman Feed-water Heater.

wrought-iron bottom for the prevention of back pressure. The whole of the exhaust steam does not pass through the heater, which is really arranged in a kind of "shunt" of the exhaust-pipes, and the exhaust steam supply to it is regulated by valves. The heater is fitted with solid-drawn copper pipes inside, through which the steam passes, whilst the water circulates on the outside. A hand hole and mud-cock, and a valve for testing the temperature of the water, are also provided.

The Engines.

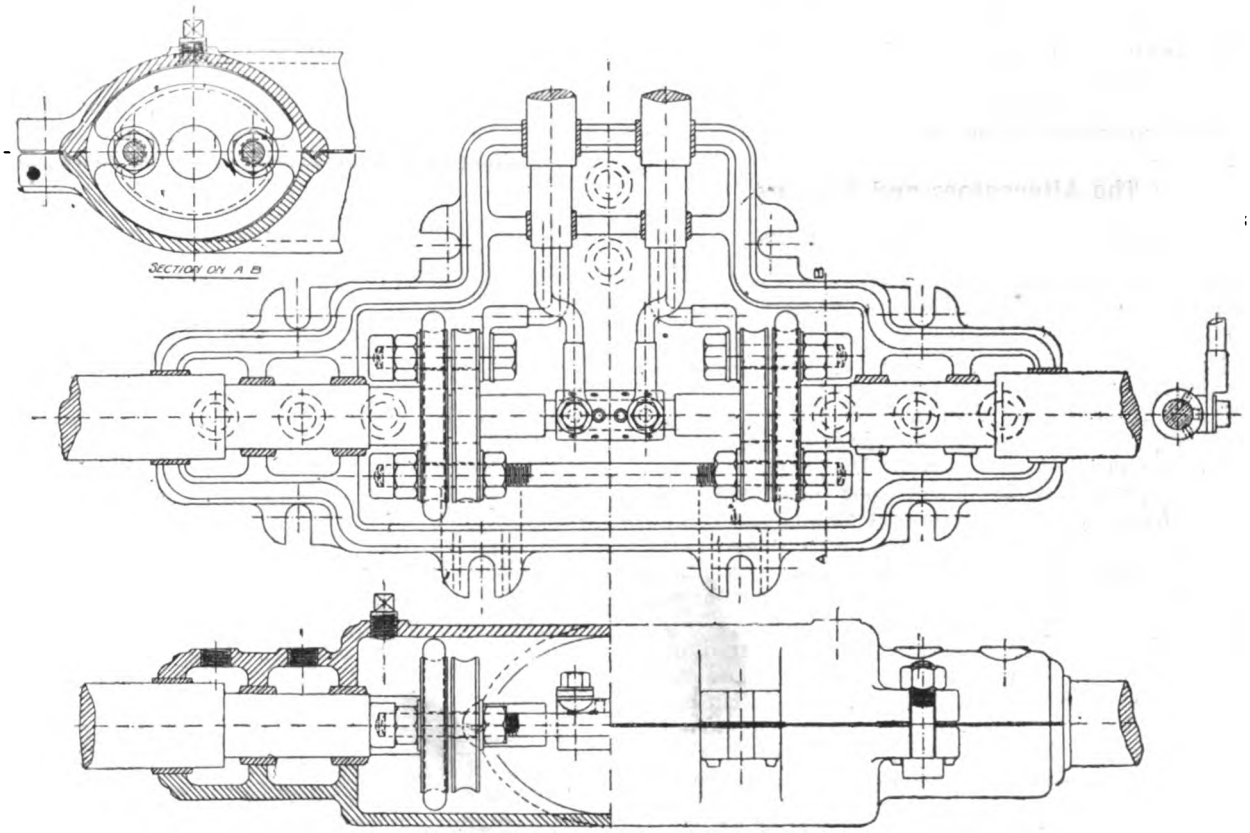
As will be seen from the cross-section of the station, the engine-house, which is 40ft. square, has been built some 9ft. above the level of the boiler-house. The engines were made by Messrs. Browett, Lindley, and Co., Limited, of Patricroft, Manchester, and details of them are annexed. They comprise two horizontal high-speed compound engines, having cylinders 11in. and 16½in. diameter and 12in. stroke, running at 180 revolutions per minute, and indicating 100 h.p. each.



Southport Electricity Works.—Plan of 100 i.h.p. Browett-Lindley Compound Horizontal Engine.

The crankshaft is 5in. diameter, and is extended beyond the flywheel to an outer pedestal bearing. The flywheel is 6ft. 8in. diameter to centre of ropes, and is grooved for 10 1in. ropes. There is also a third engine, similar to the above, having cylinders 8½in. and 12½in. diameter and 10in. stroke, running at 200 revolutions per minute, and indicating 50 h.p. The crankshaft is 4½in. diameter, and is extended with outer bearing. The flywheel is 5ft. 4in. diameter to centre of ropes, and is grooved for eight $\frac{18}{16}$in. ropes.

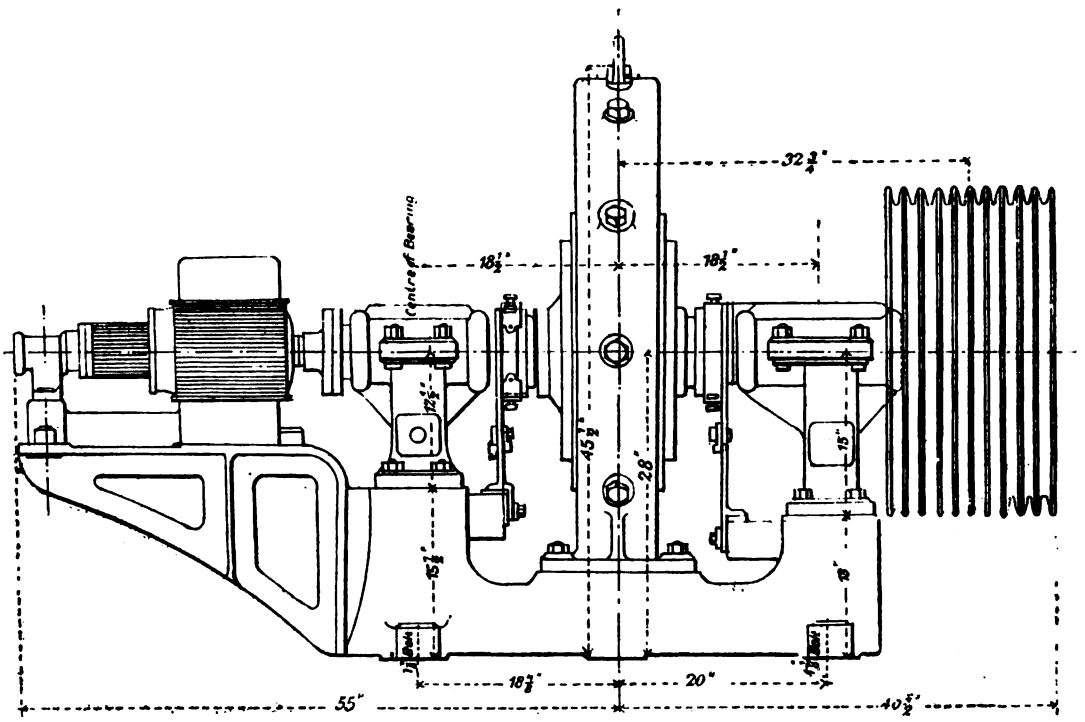
These engines are fitted with piston valve to the high-pressure and flat slide valve to the low-pressure cylinder A Porter governor controlling the speed of the engines by



Southport Electricity Works.—Plan of Siemens House-box for Serving Two Houses from Double Concentric Cable.

Digitized by Google

the throttle-valve is used. The bearings are best gunmetal lined with white metal, and Abercrombie's patent ends are fitted to the connecting-rod bolts. The governor is adjustable by hand whilst running. The lubrication is continuous, oil being taken from a central oil-box and conducted down tubes to the various bearings. Sight-feed lubricators are fitted to the cylinders. The details of these engines generally are similar to Messrs. Browett, Lindley, and Co.'s standard vertical engines, but these were specially constructed in horizontal form to conform to the engineer's specification.



Southport Electricity Works.—Side Elevation of Mather and Platt's 50-Kilowatt Alternator and Exciter.

As already mentioned, each engine is provided with two separate steam connections, and the main stop-valves are of the ordinary screw-down type. A starting valve is fixed on the low-pressure cylinder within easy reach of the main stop-valve.

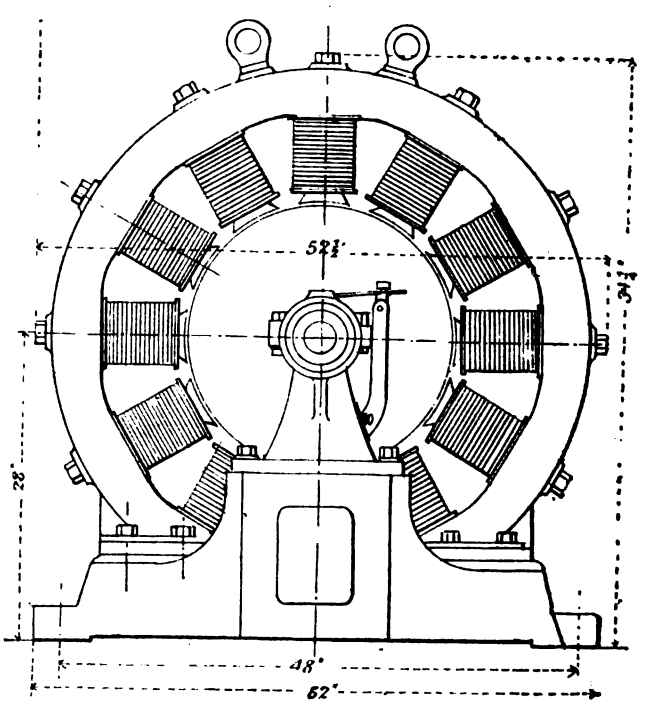
The Alternators and Exciters.

The type of generator adopted is illustrated in the side and end elevations. There are in all three alternators with the armatures revolving and the magnets fixed. Two of the machines are for a capacity of 50 kilowatts, the current being 25 amperes at 2,000 volts, with a periodicity of 50 per second and a speed of 500 revolutions per minute. The pulleys of these machines are grooved to correspond with the grooved pulleys of the two 100-i.h.p. engines. The third alternator, which is driven by ropes from a 55-i.h.p. engine, gives an output of 12½ amperes at 2,000 volts, the speed being 750 revolutions per minute. This machine has eight poles, whereas the two larger ones have 12 poles. Thus the periodicity of all is the same—namely, 50. The illustration shows that the armature coils are so arranged that it is possible to easily remove any coil required and to substitute another.

Each alternator has a direct-current exciter dynamo, coupled direct to the shaft of the alternator, and carried on a bracket bolted to the bedplate. The exciters connected with the two larger machines are each for an output of 25 amperes at 100 volts, and that connected with the smaller machine for 15 amperes at 100 volts. They are of Mather and Platt's patent "Manchester" type. The exciting current required for the full load of the larger machines is 5·75 amperes, and for the smaller machine four amperes. Thus any of the exciters are sufficient for exciting all three machines. It will be observed that the machines require exceedingly small exciting power, this resulting in a very high electrical efficiency; with full load this exceeds 97½ per cent. for all three machines. Both the alternators and exciters are manufactured by Messrs. Mather and Platt, Limited, of the Salford Ironworks, Manchester. It is a noteworthy point in connection with these machines that they may be short-circuited without detriment. The current passing through the armature, if absolutely short-circuited with the fields excited to their full extent, is less than double the normal output of the machine, which would not be injurious for a short time.

The Switchboard Arrangements.

The switchboard, which is arranged on a platform on one side of the engine and dynamo room, is represented in elevation in the accompanying illustration. As will be seen, a panel is provided for each of the three alternators and the exciters; one for the circuit board, and a fifth panel for the synchroniser. Each alternator panel carries a double-pole main switch and ammeters in the exciting and main circuit; also two main cut-outs.



Southport Electricity Works.—End Elevation of Mather and Platt's 50-Kilowatt Alternator.

The circuit panel is also provided with a double-pole main switch, double-pole cut-out, recording voltmeter, and ampere-meter. The synchronising panel is provided with

Digitized by Google

a Cardew voltmeter of the vertical type, together with switches for throwing the machines into parallel.

The switchboards and instruments have been designed and supplied by Messrs. Mather and Platt, Limited, of the Salford Ironworks, Manchester.

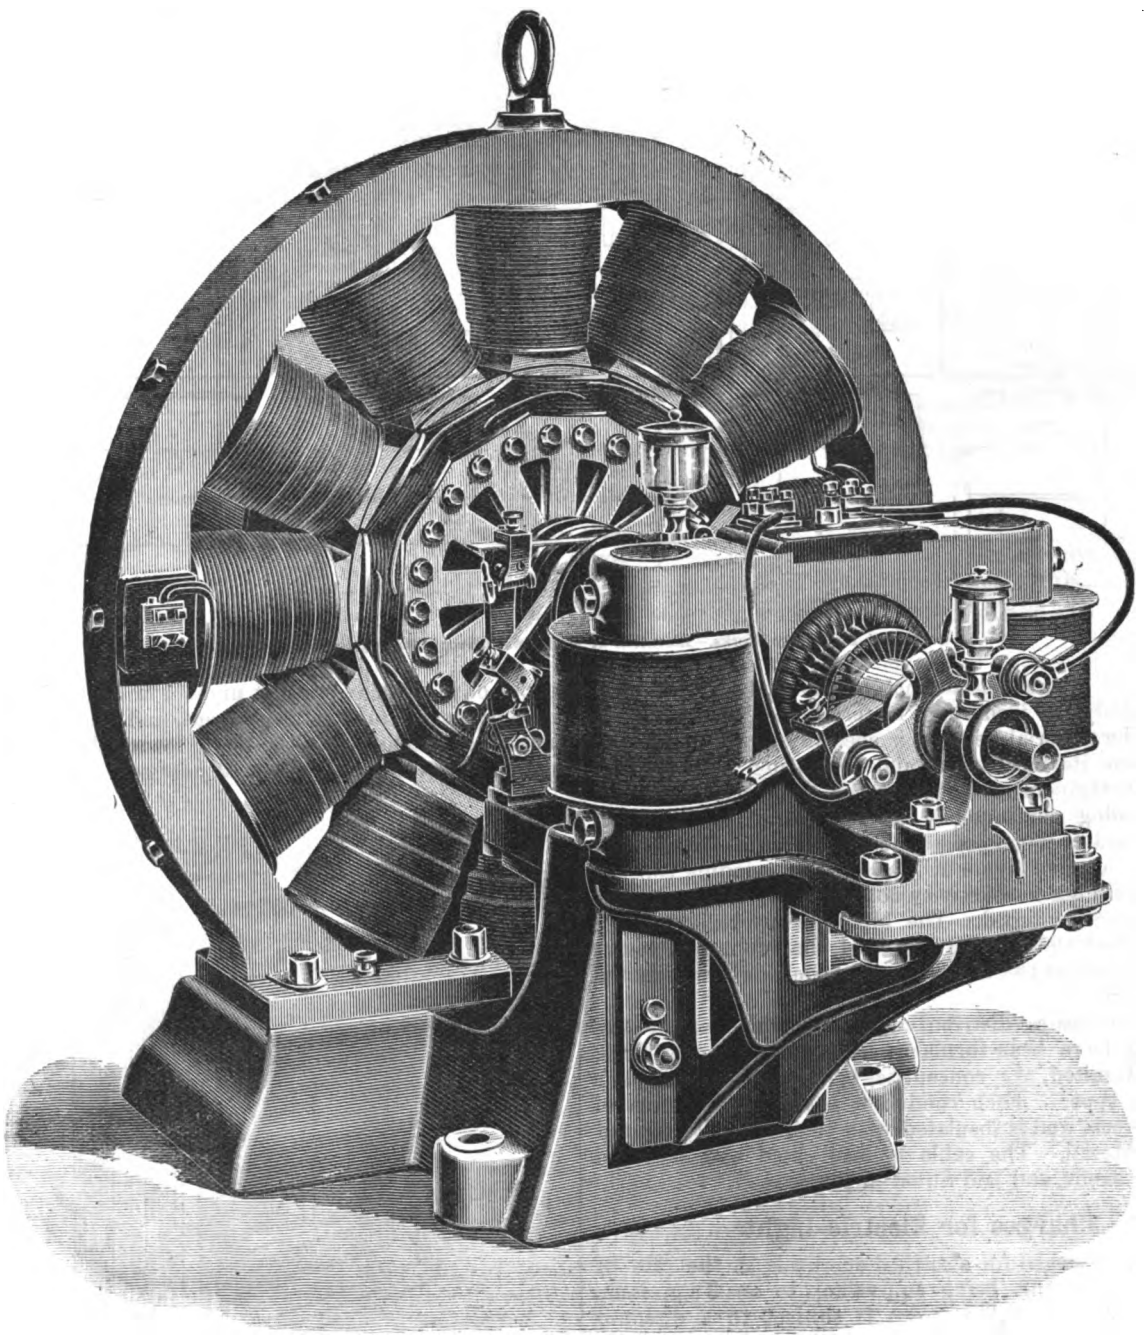
The engine-room is equipped with an overhead travelling crane capable of lifting 10 tons, the width of the span being 38ft. 6in. It has been made by Messrs. Iles, Limited, of Stanningley, Leeds.

The Feeder and Distributing System.

The feeder mains by which the 2,000-volt current is transmitted from the generating station at Crowlands to the various transformer-chambers, together with the other high-pressure mains, have been supplied by the British Insulated Wire Company, Limited, of Prescot, who, it will be remembered, furnished similar cables for the neighbouring town of Blackpool and various other towns. The feeder forms one circuit from the station to the centre of the town.

These high-pressure mains consist throughout of $^{19}/_{14}$ paper-insulated concentric cables, sheathed with lead and armoured over all and laid direct in the ground. It is noteworthy that these mains were supplied under a stringent specification: samples chosen by the engineer to the Corporation had to be cut from the cables at the works and tested with alternating currents of a potential difference of 20,000 volts. The whole of the cable had to be tested in the works in the presence of the engineer for one hour with alternating currents of 10,000 volts, and a test again after the cable had been laid and all connected up was asked for of 5,000 volts for five hours. The cable satisfactorily fulfilled all these tests. The boxes and connections, which were also furnished by the British Insulated Wire Company, were tested by the engineers to a pressure of 15,000 volts when connected up.

At present there are five transformer sub-stations, where the high-pressure current is reduced to 100 volts and distributed to consumers. These sub-stations, each of which contains a 25-e.h.p. transformer, are cast-iron chambers, pillars being arranged 3ft. 6in. above the ground for switching off and on both high and low pressure feeders.



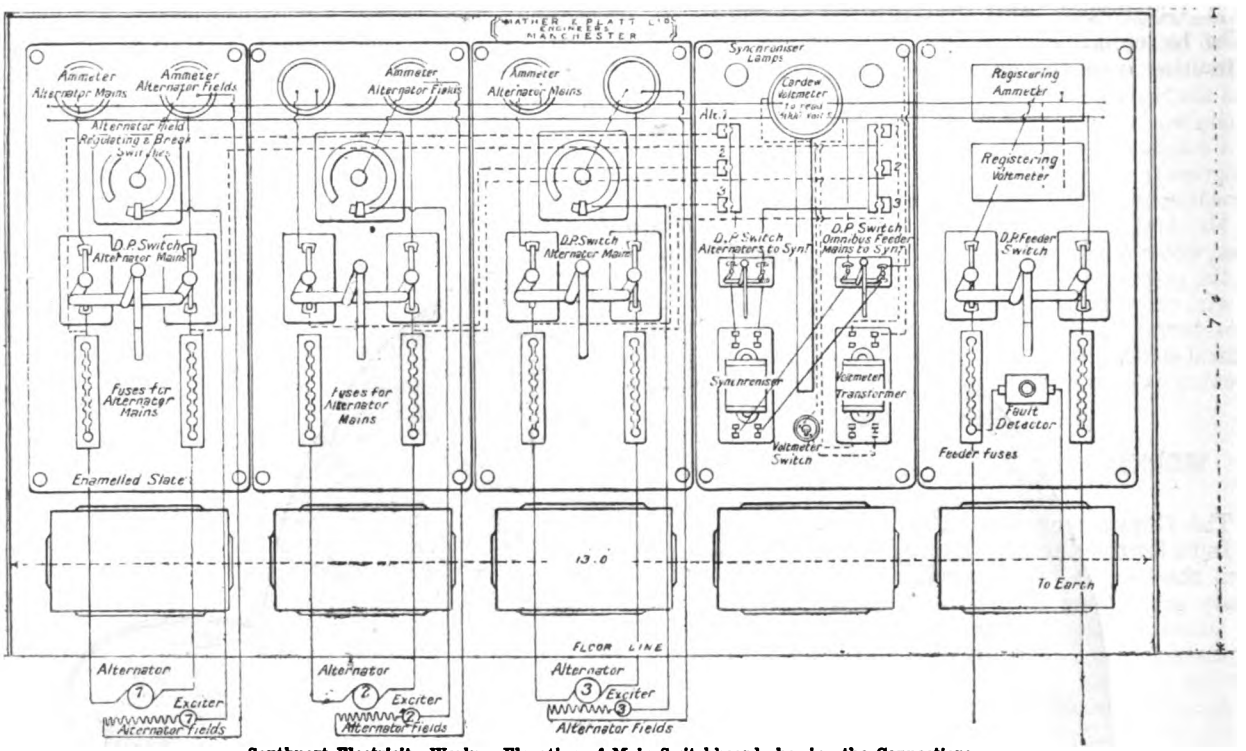
Southport Electricity Works.—Mather and Platt Alternator and Direct-coupled Exciter.

The contract for the transformers, which, together with the low-pressure distributing mains, were supplied by Messrs. Siemens Bros. and Co., Limited, of 12, Queen Anne's-gate, Westminster, London, S.W., called for five converters, each of 25 e.h.p. The type of transformer adopted is shown with the front plate removed.

It consists of a primary and a secondary winding enclosing the middle limb of a double magnetic circuit of lami-

Digitized by Google

nated iron. The output from the secondary circuit is 18·75 kilowatts, with a frequency of 50 complete periods per second, the ratio of transformation being from 2,000 volts to 100 volts. The core is built up of special stampings of very thin charcoal iron of the best magnetic quality. These stampings are built up into a double magnetic circuit of three limbs by inserting the stampings into the finished winding, the whole being clamped together by means of two strong castings bolted together. The winding is



Southport Electricity Works.—Elevation of Main Switchboard showing the Connections.

arranged on a substantial bobbin, the body of which is made entirely of insulating material and the cheeks of wood. The material being of a specially tough character, it will retain its mechanical and insulating properties at the highest temperature to which the transformer can rise when running continuously at full load. In the high-pressure coil a layer of the same material is inserted between successive layers of wires. The winding consists of turns of high-conductivity copper wire, either double-cotton covered or taped. The high-pressure terminals are insulated from the wooden cheek of the bobbin by means of ebonite, whilst the low-pressure terminals are mounted on the wood.

The low-pressure distributing mains, which, as already mentioned, have been furnished by Messrs. Siemens Bros. and Co., Limited, are concentric, being of the company's ·3 L C. N. type. Each conductor has a sectional area of ·3 square inch, and is insulated with their specially treated fibrous material. The cable is lead cased and sheathed with steel bands, and laid direct in the ground.

Charges for Electric Light.

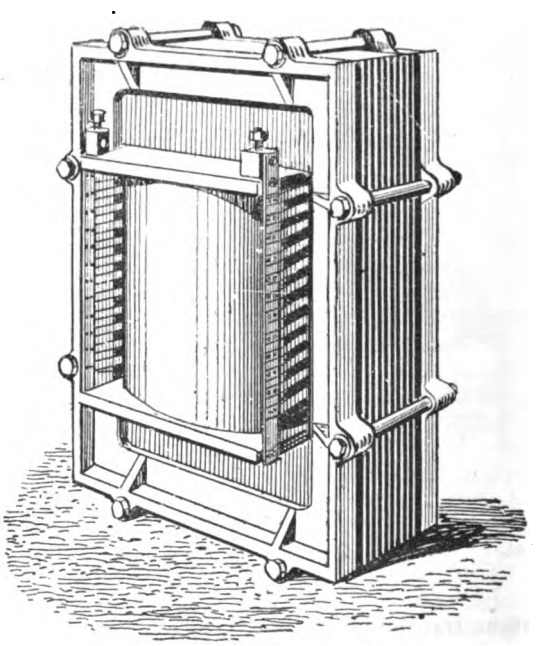
The price charged for electrical energy is at the rate of 7d. per unit, a unit being equivalent to an 8-c.p. lamp alight for 33 hours. This price is subject to a discount of 5 per cent. In addition to this, a fixed charge will be made for the use of meters for measuring the amount of electrical energy consumed by customers. This rental will be as follows per quarter, the meters being of the Shallenberger type:

Meter of a capacity of	5	amperes or	16	8-c.p. lamps,	2s. 6d.
,,	,,	,,	10	,,	,,	33	,,	,,	3s. 6d.
,,	,,	,,	20	,,	,,	66	,,	,,	5s.
,,	,,	,,	40	,,	,,	133	,,	,,	7s. 6d.

Under normal circumstances the Corporation make the connections from the distributing mains in the streets up to the meter on the consumer's premises without making any charges. In cases, however, where the meter is more than 60ft. distant from a street in which the distributing cables are laid the work of connecting up the supply to consumers cannot be done free of charge.

Private and Public Lighting.

The great appreciation shown for the electric light by the inhabitants is demonstrated by the fact that applications have already been received for no less than 5,000 8-c.p. lamps or their equivalent, being practically the whole output of the station for that number of lamps fixed. This is a most successful commencement, and there can be no doubt that extensions of the plant, for which there is ample space at Crowlands, will soon be necessary.



Southport Electricity Works.—Siemens Transformer.

As far as public lighting of the streets by arc lamps is concerned, the Southport Corporation have hitherto done nothing. With its fine Promenade and Lord and other prominent streets, the town cannot very well dispense with this desirable acquisition—a means, too, which for no other consideration is an excellent advertisement for the town and an attraction for visitors. Southport must of necessity follow the example of its neighbour, Blackpool. It will do

Digitized by Google

so, we are glad to hear, and early next year it is intended to erect 24 series arc lamps arranged on the high-pressure direct-current system. Two arcs are already being fixed in London-square to see how they work with 50 periods per second.

Conclusion.

A pretty sight should be seen this evening, after the formal inauguration of the electricity works, in front of the Town Hall in Lord-street. The Town Hall and the adjoining Cambridge Hall will then, for the first time, be lighted by electricity, whilst the trees and gardens in front thereof are to be studded with incandescent electric lamps.

In concluding this short description, we must congratulate the Southport Corporation on having established electricity works rather than allow their powers to be transferred to a company. In doing so they have not only followed the progressive spirit of the times, but they have conferred a benefit upon the Southport community. Our thanks are due to Mr. Arthur Ellis, A.I.E.E., the municipal electrical engineer, whose photograph we reproduce, for his kind assistance in the preparation of this article, and it only remains for us to wish prosperity to the Southport electricity works, which, considering the capacity of the plant, stand out unique in central-station working with an initial demand on the opening day for 5,000 8-cp. lamps.

WORKING OF THE INDIAN TELEGRAPHS.

The Government resolution on the telegraph systems in India for the year 1893-94 shows what a profitable concern this branch of the service is: notwithstanding the heavy expenditure incurred in additions to lines, increase of accommodation, plant, and apparatus, the net return on capital to the State was 4·61 per cent. The details of outlay, says *Indian Engineering*, from the commencement of telegraphic operations aggregate the enormous total of 566 lakhs of rupees, of which 22½ lakhs were spent during the year. The additions made during the year were 1,677 miles of line and 8,004 miles of wire. The working expenses were Rs. 53,04,761, while the revenue receipts amounted to Rs. 80,07,306. The working expenses of the new line from Srinagar to Astor, 187 miles in length, while showing an increase in expenditure of Rs. 1,47,763, also showed an increase in the revenue of Rs. 4,24,133, giving a net return to Government of Rs. 2,76,369. At the close of the year the Telegraph Department possessed 3,627 offices, 42,707 miles of line, 134,255 miles of wire, and 274 miles of cable. The principal source of revenue was derived from private messages, which show an increase of 194,480 on inland and 14,266 on foreign messages, giving a net increase of 5·11 per cent., or Rs. 4,03,668 in excess of last year, the highest figures yet attained. A marked increase is also noticeable in the revenue derived from inland deferred messages, the tariff of which was reduced in 1891-92. The latter results go far to prove that further reductions in the tariff can be made without a loss accruing to Government, and that the public appreciate the concession and more readily take to telegrams. This reduction might equally apply to foreign messages, the charges for which are exorbitant or deterrent. A special feature in the report is the introduction of a new signalling apparatus, termed "the Melhuish transformer," which claims to improve the speed of transmission of messages over long distances and to decrease signalling operations to a minimum. It is said that by its use a reduction of establishment representing approximately Rs. 64,000 per annum has been effected. Further experiments are being tried with the quadruplex working, to see whether the new apparatus would be equally serviceable as in the duplex system, and for which purpose circuits have been fitted up at Calcutta and Agra and other large centres. Experiments with dry batteries, and the feasibility of transmitting simultaneously on a single wire two kinds of currents directly opposed to each other, so that the current may operate on the instrument intended without interfering with the other, are also pro gressing. The report on the whole is very satisfactory, and is a marked advance on previous records.

ELECTRIC LIGHTING IN GERMANY.

Messrs. Schuckert and Co. are going to erect a new central station in Hamburg. Mr. Oskar von Miller reports, in connection with the proposed scheme for the electric lighting of Nuremberg, that the private applications for current in response to circulars have been far more than was anticipated, amounting to 26,000 16 c.p. lamps and to 450 h.p. in motors. The original scheme will consequently have to be extended. The whole of the buildings of the municipal slaughter-house at Bomberg have been lighted electrically by the Allgemeine Elektricitäts-Gesellschaft, of Berlin. The local authorities of Königshütte have received applications for a monopoly for a central electric light station from the firms of Messrs. Stutzer, of Myslowitz, and Messrs. Ernst Sattler. A committee has been appointed to enquire into the whole subject. Tenders have been received from a number of firms for the electric lighting of Mayence Harbour, but none have been found suitable. The firms are to be asked to tender anew. A central electric light station is being erected at Rendsburg. The Municipality of Neurode are projecting a central station. Plans have been worked out by the Heidelberg Cement Works for utilising the power of the River Neckar, there being about 3,000 h.p. available. They propose to supply Heidelberg with the electric light. The supply station which is being erected in the Neuenstrasse, Brunswick, will shortly be put into operation. The mains at Hanover are being extended. The Liebfrauen Cathedral at Munich is the first Roman Catholic church in Germany to have been lighted electrically, though there was some clerical opposition on the theory that wax only should be burnt. However, there is now some chance that the Cologne Cathedral will be lighted by electricity. The Allgemeine Elektricitäts-Gesellschaft intend to erect in Harburg a central station for the supply of current for lighting and power purposes. Tenders have been received for the electric lighting of the chief Royal works at Wiesbaden from Messrs. Siemens and Halske, of Berlin; Messrs. Schuckert and Co., of Nuremberg; and Mr. C. Buchner, of Wiesbaden. The last named has obtained the contract. The Municipality of Linden have declined to accept the offer of Mr. Bremeyer to establish a central electric light station in the town, but the Hanoverian Bread Factory now propose to bring forward another scheme. There is a good demand for current at Flensburg. At first there was only one dynamo running, a second has since had a trial run, and a third is to be installed before the end of the year. The Frechener Elektricitätswerke have received a 25 years' concession for a central electric light station at Remagen. Messrs. Alioth and Co., who have 120 h.p. to spare at their works at Mönchenstein, have made an offer to light Dornach-Brugg electrically. Messrs. Lahmeyer and Co., of Frankfort-on-the-Maine, propose to erect a central electric light station at Diez, Naussau.

INSTITUTION OF ELECTRICAL ENGINEERS, Nov. 8.

MR. ALEX. SIEMENS in the chair.

The two papers announced in our last issue were read yesterday evening, and one is given in another column. There was no discussion, and the meeting was adjourned until the 22nd inst.

Telegraphy in India.—Orders have now been issued for the telegraph offices to be closed on the Gohna and Hurdwar lines, and for the line to be dismantled. At the request of the Postmaster-General (N.W. Provinces and Oudh), the executive engineer (Benares Division) has submitted a modified plan and estimate for constructing a new combined post and telegraph office at Korantadih, the headquarters of the Ballia district, at a cost of Rs. 5,150, for administrative sanction of Government. The Madras Chamber of Commerce has been asked to submit through the local government its address on the question of the reduction in the telegraph rates to and from England. It seems unlikely, however, that anything can be done in the matter.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIII. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

THOSE BOGIES.

The President of the Institution of Electrical Engineers, speaking at Bolton, mentioned two bogies which are continually flaunted in the faces of all and sundry by the opponents of electricity in their endeavour to frighten municipal bodies from dealing with the question. One of those bogies is of greater far-reaching importance than the other, in that it concerns every householder. The two bogies are: first, the cost of electric lighting to the householder; second, the fear of the gas shareholder that the development of electric lighting will ring the death-knell of the gas industry. Our interest is at present more concerned with the first of these bogies, and the weighty remarks of Mr. Siemens ought to be sent broadcast throughout the kingdom. Of course, opponents will still say they are the words of a deeply-interested party, but we can assure them that the facts can be corroborated on all sides. They are true, and cannot therefore be gainsaid. The difficulty is to bring them home to the minds of householders. Then we may be asked to reconcile two conflicting statements made on the same day—the one at the opening ceremony, by Alderman Miles, the energetic chairman of the Bolton Lighting Committee; the other, the one referred to above, by Mr. A. Siemens. Alderman Miles in his remarks referred to the cost of electricity being one and a half times that of gas. He was comparing the cost of equivalent amounts of electricity and gas, and meant that if a thousand cubic feet of gas cost three shillings, an equivalent amount of electricity would cost four shillings and sixpence. Assume that to be correct, Mr. Siemens, without controverting or in any way questioning the statement of Mr. Miles, said that his own experience with electricity at eightpence per unit, which is more than one and a half times the cost of gas in that particular district, was that his quarterly bills for electricity were not more than the quarterly bills had previously been when gas was the illuminant used in his house. In other words, he stated that though electricity might, compared unit for unit with gas, cost more, the actual bills for the light did not come to more—and that is the crucial test. We have always contended that if the bills were indeed more, the incidental advantages of electricity are so great that the total household cost for illumination would be less. Mr. Siemens, however, meets the question directly by saying the cost according to his household bills is not more, and he accounts for the fact in a simple manner. He maintains that for useful purposes the electric light has never been stinted, but that the gain is wholly derived from not wastefully burning it. The whole house is duly fitted with electric lamps, and the lamps are controlled by switches. The result is that when a lamp is wanted it is turned on, and when not wanted it is turned off. With gas the opposite is the case. There is more trouble in lighting. You do not turn a switch on or off at the doorway with gas, but you can, and do, with electricity. The whole of the gas lamps, or the larger part of them are lighted at the

Digitized by Google

beginning of the evening, and turned up or down as required. Now, that is just the point which allows electricity to directly compete. Gas is being consumed whether the burner is high or low. To be put upon a favourable position, it should be completely turned out when not wanted and lighted when wanted. But that involves too much trouble. The more these facts can be brought home to householders the better it will be for the electrical industry. We think, then, that the statements of Alderman Miles and Mr. Siemens are easily reconciled, and that each may be perfectly correct. It must not be considered that the facts as given by Mr. Siemens are anything extraordinary. They are valuable from being the results of actual experience. Almost in the infancy of the industry the late Mr. J. E. H. Gordon brought forward similar figures. In his case, however, if we recollect rightly, the cost of electricity was actually lower than that of gas—"although," as the gentleman put it, "we have been entertaining at our house more liberally this season than last, and consequently have required more light." It is wonderful how largely the unutilised consumption of gas bulks out the gas bills. Let those interested in electricity gather together these experiences and place them before the public at every opportunity.

As regards the other bogie, it was hardly worth combatting. The introduction of railways has not lessened the demand for horses; and while all the chemical by-products of gasworks are so valuable, while it possesses admirable heating properties, there seems to be little or no prospect of adding gasworks to the lumber of old museums. We admit that progress in any direction may mean, and unfortunately too often does mean, individual troubles. Man is an adaptable animal, but too often he does not adapt himself to circumstances. Smith, Jones, and Robinson have troubles because of the introduction of machinery, but their troubles mean success to other artisans. The world is not to stand still in its illuminating process because gas takes a large place in the field, does not like to be turned out, and is somewhat troubled by the progress of its latest competitor.

REVIEWS.

The Slide Rule: A Practical Manual. By CHARLES N. PICKWORTH, Wh.Sc. Fifty-six pages. Price 2s. Emmott and Co., Limited, Manchester and London.

There are slide rules and slide rules, from the 6in. length of brass let into a mechanic's rule to the elaborate Gravêt appliance of mahogany and celluloid or the logarithmic calculating tables of Billeter; but all are based for any real service upon the use of logarithms in the simplification of the mathematical processes that involve the treatment of large quantities. The author of this little book rightly, therefore, takes first in hand the consideration not only of the mechanical principles upon which the ordinary slide rule is based, but also of the mathematical processes involved by the logarithmic calculations, and this first section ought alone, we think, to prove of value to many electrical engineers who either have not had the advantage of more than a rudimentary mathematical training, or through pressure of other things have let slip some of the knowledge they may long ago have acquired.

Under such conditions the author confines his attention largely to the Gravêt slide rule, as being, perhaps, the most modern type, and starting with this he takes up the various applications of the rule to solving mathematical problems of all kinds by logarithmic principles. Ranging from proportion, through multiplication, division, involution, evolution, the author follows with a vast mass of examples in technical computation, such as all engineers have to deal with continually. Of course for slide rule work it is necessary to employ a series of conversion factors, and a very complete set of these has been provided by the author. Taken on the whole, this little book has many points to recommend its use both for beginners in engineering and those who merely require a handy work for reference: whilst the few criticisms which we might conceivably make upon it in one direction or another are not in any way material except from a particularly captious point of view.

PROPOSED ELECTRIC TRAMWAY AT ACTON.

In a recent issue (see the *Electrical Engineer* of October 19 last, page 447) we suggested the desirability of the Acton District Local Authority taking immediate action to expedite the equipment of an electric tramway along the route between Shepherd's Bush and Acton, where the tramway company proposes to double the existing single track: and we then urged the serious consideration by the Local Board—conjointly with the tramway interests—of all the numerous advantages to be derived from the adoption of such a proposal.

On enquiring further into the matter we learn that the tramway management practically consists of the same progressive spirits that have so ably and successfully determined upon electrically operating the tramway systems at Bristol and Dublin, so that we may at once assume a ready acquiescence and willingness on their part in regard to adequate discussion of any proposal emanating from ourselves, the local authority, or other source having electric traction as its main object. We are, therefore, still more desirous of urging the powers that be to at once consider with the utmost favour the suggestions made in our previous article. There should be no need for us to further emphasise the importance of electric traction at the present time as evinced by the developments of the past 10 years in the United States and on the Continent: anyone who has followed its rise and progress will fully appreciate the enormous advantage of a trolley-wire system in improving, if not practically renewing entirely, the capabilities of street tramway transit consistently with modern ideas and requirements; and the same reasons that hold good abroad are quite as potent if not, indeed, much more so, for effecting a change in this country also.

From what we have been enabled to ascertain with respect to the interests that govern the London United Tramway lines, we should feel confidence in asserting that the matter may be very easily arranged favourably for all concerned, and in view of the possible ultimate adoption by the local authority themselves of the *electric lighting* powers for this district (instead of leasing them to a company), it would seem most distinctly advantageous for these facilities to at once be given for the equipment of an efficient and up-to-date electric tramway. Of course we hold no brief for the tramway company (other than by reason of their progressive spirit shown in being favourable to and even desirous of the adoption of electric traction), and we do not pretend to speak for them; but we make no doubt that if the electric line be, as we hope, fully sanctioned and approved by the local authority, the tramway company would be only too pleased to avail themselves of a supply of electric energy for working their line, derived from the electricity works employed for the electric *lighting* of the district.

Not only would such a course of action save the tramway company the expense of erecting an electric supply station (thereby enabling them to spend more upon wood paving or other desirable improvements in the tramway service), but it would also ensure to the local authority as the owners of the electric *lighting* works an immediate and constant source of revenue *throughout the daytime*, when,

Digitized by Google

as everyone knows, the demand for a lighting current is practically nil.

Following on all these considerations, it is therefore abundantly clear that this line—if only as the pioneer electric trolley wire system in the Metropolis—deserves the fullest possible support from all concerned, and we are greatly pleased to think that a hearty and unanimous approval is being accorded to the proposal by all those who have the true interests of the district at heart.

CITY AND GUILDS OF LONDON INSTITUTE.

LECTURE IX.—THE CONSTRUCTION AND ACTION OF ELECTRIC BELLS—THE ARRANGEMENTS OF BATTERY CELLS, AND OF CIRCUITS FOR BELLS.

(Specially contributed.)

The Electromagnet.—We have seen that an electric bell circuit contains, besides the battery, a contact maker or push, the wire connections, the bell, and sometimes an indicator. Let us, for the time being, examine the bell, which from its name you will understand is worked electrically—that is, the hammer or striker is caused to strike the gong, or sounding portion, by means of an electric current.

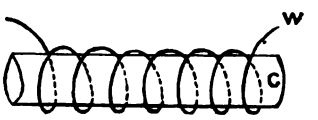

FIG. 1.

I have here a number of pieces of soft iron, cylindrical in shape, each piece having the well-known characteristics of iron. Around this piece of soft iron I wind an insulated wire, Fig. 1. The iron we call the core, and the wire the coil. By means of this silk thread, I hang the piece of iron, A, thus treated to this hook.

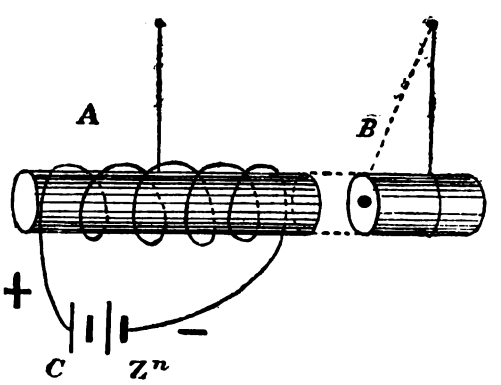

FIG. 2.

I take a second piece of iron, B, and hang it by a silk thread to another hook so that one end of B is near one end of A, Fig. 2. You see the two masses hang quite still.

I connect the ends of the wire on A to the terminals of the battery, and directly this is done you see the iron mass B moves till it touches A. We know that by connecting the wire of the coil to the battery an electric current is sent through the coil, and the action of this current has seemingly imparted to the iron core some property or properties which it had not before. The property immediately clear to us is that the iron of B is pulled or attracted to the core of A. The piece of iron around which the coil is wound, and round which a current is now going, is called an electromagnet. The properties pertaining to an electromagnet will be the subject of future investigation. The one shown is enough for our present purpose. The property of pulling a piece of soft iron is not restricted to one end of the core, as may easily be seen. First, I will break contact with the battery. You see B does not return to its original position, and that is because the core does not at once lose all its new properties. A slight pull, however, suffices to bring B away, and after a few gentle taps on A with this ruler, when I bring B into touch, it goes back to its old position at once. The core around which the current flows is said to be magnetised, and when the current is stopped a little of the magnetism is retained by the soft iron core, and this is called the *residual* magnetism.

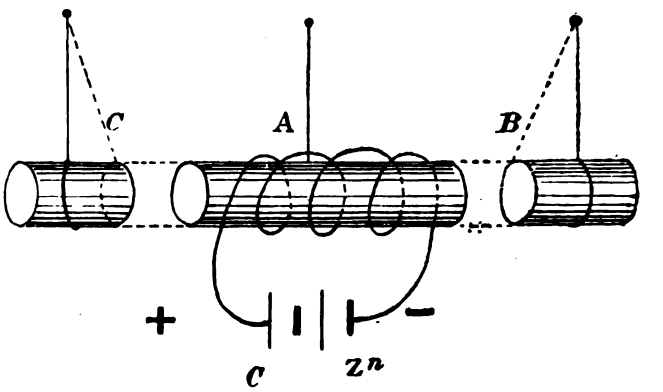

FIG. 3.

I hang another piece of iron, C, at the end of A, Fig. 3, opposite B, and make contact with the battery. Directly you see both pieces of iron are pulled into contact with A. Both ends then exert a pull on the other pieces of soft iron.

Horseshoe Magnet—In order to utilise this double pull electromagnets are frequently made bent into a U-shape, and because of their shape are called horseshoe magnets. The piece of iron, A (Fig. 4), opposite the ends of the magnet is called the *armature*, or keeper. The ends of the magnets are called its *poles*. The U-shape is not always easy to make, so that it is frequently modified, and the bent part is made straight, as in Fig. 5. The various parts of an electromagnet are then :

The armature, A ;
„ iron core, C ;
„ surrounding coil of wire, W.

The core again may be divided into
The arms ; and
The yoke, Y, or piece joining the two arms.

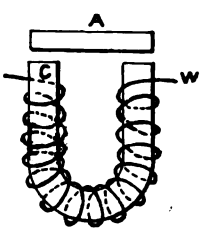

FIG. 4.

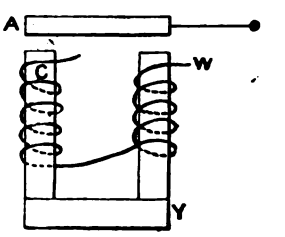

FIG. 5.

The ends of the core are called the poles, and the air-space between the poles is either called air-space or air-gap.

In Fig. 5 the armature is shown connected to a fixed point by means of a strip of steel which acts as a spring.

When a current is sent round the coil the armature is pulled to the poles, and when the current is broken the spring brings it back to its original position. The ends of the core are often covered with a little paper or thin brass,

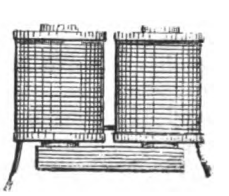

FIG. 6.

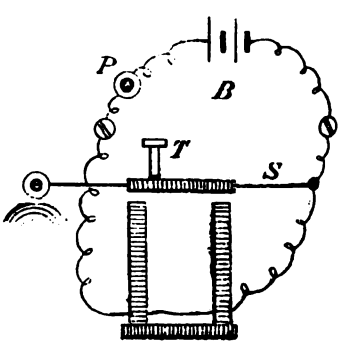

FIG. 7.

so as to do away with sticking caused by residual magnetism. With this apparatus you will see how easy it is to cause a bell to sound. I have only to fix a hammer to my armature and adjust this in connection with the gong of a bell, and then make contact with a battery. The

Digitized by Google

electromagnet pulls the armature, causing it to move through a certain distance, and with it moves the hammer, and by such motion the hammer can be brought into contact with the gong, or, in other words, the bell is struck.

The electromagnets used with bells are a little better made than the rough one I just now wound. Here is one, Fig. 6, similar to those in these bells. First let us examine this

Single-Stroke Bell, so-called because when contact with the battery is made it gives one stroke. The diagram, Fig. 7, will show its action. When the connections are made the current goes from the C plate of the battery, through the coils of the electromagnet, to the Zn plate of the battery. On the side of the armature opposite the magnet poles is a screw, the position of which determines the distance of the armature from the poles. The armature is fixed at one end through a spring, S, and at the other end carries a hammer. Now, if the armature is pulled sharply down on the poles, the hammer is so fastened that it has a little play and goes, or should be adjusted to go, slightly beyond the line of the armature. It comes to rest, however, in the line of the armature. By this means when properly adjusted to the gong, and the armature falls, the hammer strikes the gong and immediately comes to rest at a very little distance from the gong. I am supposing the current flowing all the time, otherwise armature and hammer go back to the original position. The reason why the hammer is wanted to move away from the gong you will easily see. The bell sound is caused by the vibrations of the gong, and if anything touches the gong

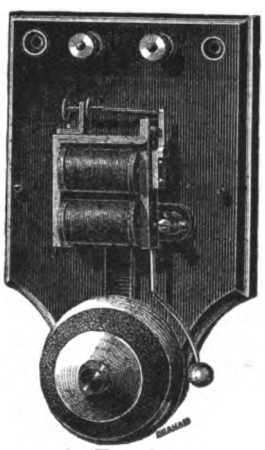

FIG. 8.

it stops, or damps, or muffles the vibrations, and instead of a clear distinct tone you get something of a sound of the nature of sharpening a saw. We make our contact and then break it; you see the armature move, the hammer strikes and you hear the sound. It is all very simple. It is not necessary, of course, to have hammer and armature in a straight line, for the adjustment can be made as in Fig. 8 quite as well. The single-stroke bell is very useful for many purposes, especially for certain parts of

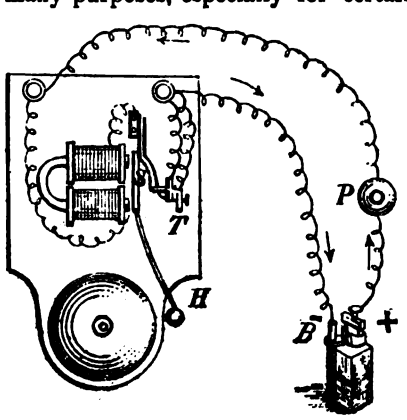

FIG. 9.

railway work. Here a single stroke means one thing—a train on line from A to B, for example; two strokes mean train on line from A to C; three strokes, one from B to A, and so on; but to rouse an hotel waiter or an ordinary servant a bell of another kind is usually employed, one that goes ting-a-ling-ling as long as the contact is made.

The Vibrating or Trembling Bell.—In this the connections are different to those of the single-stroke bell. They will be better understood by an examination of the diagram, Fig. 9. In this we have shown the battery, the push, P, the electromagnet, with its armature fixed to the spring, S. This spring, when the coils of the magnet have no current through them, rests against an adjusting screw, T. The adjusting screw is connected to the other pole of the battery, as shown in the diagram. When contact is made at the push, P, the current goes along the wire,

FIG. 10.

as shown by the arrows, to the coils of the magnet, through these coils to the spring, S, and screw, T, and so back to the battery. As soon, however, as this circuit is completed, the magnet pulls the armature, causing the bell to ring, but the movement of the armature breaks the circuit contact at the screw, T. There is now no current able to get through the circuit because of the break, and therefore the magnet ceases its pull. The armature goes back to its original

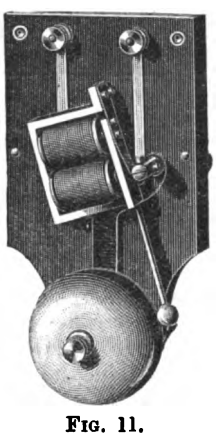

FIG. 11.

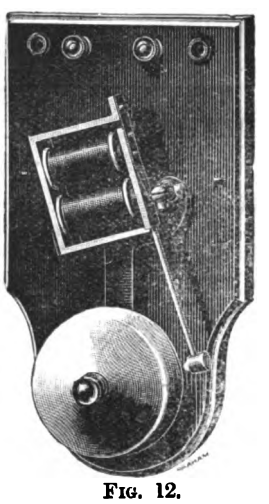

FIG. 12.

position again, makes the circuit complete through T. Again the magnet acts, the bell rings, and so the matter goes on as long as the push, P, makes contact. Of course, when P is released the circuit is absolutely broken, and cannot be made automatically. A section of the push, Fig. 10, shows how contact is made by pressing P. It usually consists of an ivory knob moving loosely through

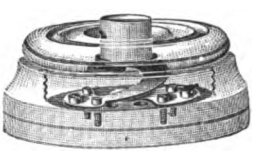

FIG. 13.

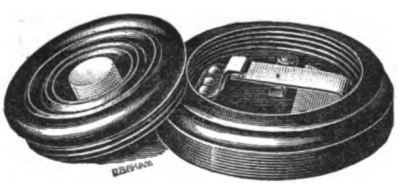

FIG. 14.

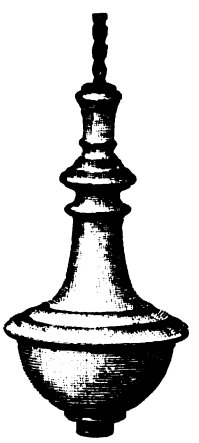

FIG. 15.

a hole in a support of wood or porcelain, which, when pressed, forces a spring against a metal disc, completing the circuit. Figs. 11 and 12 show forms of trembling bells, and Figs. 13, 14, and 15 show forms of pushes.

Digitized by Google

The various points of contact are generally made of platinum; thus the tip of the screw, T, ought to be of platinum, as ought the part of the spring of the armature attachment that it makes contact with. One reason for this is that even in such contacts minute sparks, especially on breaking contact, are formed, which rapidly wear away iron. Then, again, iron soon rusts and gets eaten away, so that good contacts are difficult to make. Mr. Allsop tells us that to adjust a trembling bell it is necessary to make sure that all the connections are tight. Thus hold the hammer against the gong and set the screw, T, till its platinum point is just clear of the contact on the spring, S. Let the hammer go, and see if the spring draws the armature back to make good contact with T. The armature, when attracted by the magnet, should be just clear of the magnet poles when the gong sounds. If the screw, T, is screwed up too far, the spring will not break contact with it, while if not far enough the hammer may not reach the gong, or touch it only feebly so as to produce little sound.

Sometimes a bell rings badly from the spring either setting the armature back too strongly, or from being so weak that it does not bring it back with sufficient rapidity. To find out which is the true cause, take a piece of wire, or, better still, a piece of watch spring, and whilst the bell is ringing press the armature towards the poles; then, if the ringing is improved the spring is too strong, and must be taken off and set a little inwards. If, on the contrary, the ringing improves when the armature is pressed away from the poles, the spring is too weak, and must be set a little outwards.

THE EFFECTS OF HIGH-FREQUENCY ELECTRICAL DISCHARGES PASSED THROUGH THE BODY.*

BY ELIHU THOMSON.

The writer has from time to time conducted experiments that prove beyond question the conduction through the body of currents or discharges, the heating effect of which in a carbon filament, whether enclosed in a vacuum or not, is equal to that which is given by continuous currents of from ·3 to 1·5 ampere.

There is little or no sensation experienced in such passage provided the surface of contact of the electrode with the skin be not too restricted. It is needless to mention that with ordinary alternating or continuous currents the passage through the arms of so small an amount as 20 to 50 milliamperes may be quite painful.

The apparatus used in my experiments may be described as follows. Ordinary alternating currents of 125 periodicity are passed through the primary coil of a special transformer or induction apparatus, the secondary of which is wound to give currents of about 20,000 volts. The secondary terminals have attachments to the two sides of a large condenser, whose capacity may be changed at will. Its construction is such that it resists perforation of its insulating dielectric layers. Each dielectric layer is composed of two sheets of built up mica about $\frac{1}{8}$in. thick each. Between these double layers the foils are placed and the whole is covered with oil contained in a wooden box or receptacle. This condenser discharges across two air spaces or gaps, through which a strong air blast from proper jets is kept blowing. The gaps are formed between two sets of brass balls, and arrangements are made to connect to the outer ball of each pair any part of a circuit or path which it is desired that the condenser discharge shall take. A plain coil circle or loop of wire, bare or insulated, may form this discharge path. According to the self-induction of this loop and the capacity used in the condensers will depend the rate or frequency of oscillation of the discharges of the condenser crossing the air-gaps. A larger condenser gives a slower rate, as does also a loop or discharge circuit of larger area or self-induction. Hence, it is easy to make the discharges rapid enough to represent rates of 30,000, 50,000, 100,000 oscillations per second, as desired. It must not be supposed that in such an apparatus we can obtain a continuous unbroken set of waves of current like that of an ordinary alternating current, but of high rate. On the contrary, what we do get is a broken set of discharges in which the times occupied by the discharge itself, oscillating while dying out, is small compared to the periods of rest or no discharge.

A brief outline of some of the work may be of interest at this time. The first point to determine was the virtual resistance of the body from hand to hand and to secure, if possible, a passive substitute resistance which could be used instead of the experimenter himself in further tests where needed. Such resistance substitutes were made by taking boxes about 2ft. long 1ft. wide and 6in. deep, and filling them with sawdust dampened with a weak salt solution. Copper-plate electrodes with short heavy cables attached could be inserted into the sawdust at any point in the length of the boxes. Now, placing the body in circuit with an incandescent lamp burning at a given brilliancy it was easy to reproduce the same brilliancy in the lamp by using, instead of the body, the sawdust-box and adjusting its electrodes, all other conditions remaining the same in each experiment. A measurement of resistance of the box made at once after the substitution by passing through it a current due to 106 volts, and measuring the current which passed, gave a resistance of 750 ohms. A similar substitution of a water resistance gave 650 ohms, so that approximately the virtual resistance of the body of the experimenter could be taken at 700 ohms.

The contact with the palm of the hand was made by metal surfaces tightly grasped and having about six square inches contact with the palm and fingers. By substituting a water rheostat for the body and adjusting it to have the same resistance as indicated by the lamp brilliancy, the increase in temperature of the water during a given time could be made the means for determining approximately the rate of actual heat energy delivery to the body, assuming it to act simply as a resistance, an assumption which, so far at least as the conversion of current energy into heat is concerned, is doubtless well founded. It was found that the rate of heat delivery to the water was equivalent to 59 watts, or about 2,600 foot-pounds per minute. The significance of this delivery of heat energy is plain. Heat energy may be delivered to the body or a portion of it without exciting the muscles or sensation. Whether this method would for the purpose of the physician have any advantage over the application of warmth externally is not of course yet understood. On account of the dead spaces and the nature of the discharges in these experiments the maxima of current must be high. It is possible that the greatest wave amplitude may give 10 amperes or more as a maximum.

In some of the experiments, instead of shunting the discharge loop or coil as described, the arrangement was modified by using a secondary parallel loop or coil, the inductive relation of which to the first or primary could be varied. With a single circle of heavy wire the diameter of which was about 3ft., constituting the primary or condenser discharge loop, a secondary of three turns of heavy okonite covered wire coiled to equal diameter with the primary was sometimes used as the source of high-frequency discharges to be applied in the tests. By moving the secondary into more or less exact parallelism with the primary, the force of induced secondary currents could be regulated at will. From the terminals of such a secondary connections are made to the electrodes used in conveying the currents into the body.

By bringing the terminals of such secondary to a distance of about $\frac{1}{4}$in. apart a torrent of heavy brilliant sparks accompanied by a very loud roar would be obtained, yet, without altering the conditions, such secondary terminals could be bridged by the body, or short-circuited, so to speak, by the hands, with impunity, provided only that the contact surface was not too restricted. It was this coil which, when circuited through the arms immersed in salt solution, gave a current of heating effect equivalent to 1·5 amperes, as above described. The lamp used in this case was rated at 25 volts, 3·5 amperes, and was brought to redness by the current passing through it and the body in series. The brilliancy being carefully noted could be reproduced by an ordinary current of 1·5 amperes.

* Abstract of a paper read before the American Electro-Therapeutical Association, New York, September 25, 26, and 27, 1894.

BOLTON ELECTRICITY WORKS.

In our last issue we gave a full description of these works, merely, however, stating that they were formally opened on October 31, so that a little more detail of the opening ceremony may not be amiss. Exactly at the time appointed, 4.30, the Mayor (Alderman Nicholson, J.P.), in his robes of office, came upon the switchboard gallery, accompanied by Alderman Miles, J.P., the energetic and painstaking chairman of the Gas, Street Lighting, and Electricity Committee, and the following members of the committee: Alderman Dobson, J.P., Councillors Finney, W. Cooper, J.P., Sherry, J.P., Kearsley, Tootill, Panton, and Holt, the town clerk (Mr. R. G. Hinnell), and Mr. Rider, electrical engineer. The town clerk read an official statement relating the rise, origin, and progress of the scheme. The Mayor then said it was a gratifying circumstance to him that he happened to be mayor on the occasion such as they had met that day to inaugurate. There was no doubt that the day was a very important one in connection with Bolton. No one could foretell what splendid results might arise from the introduction of that new lighting power into Bolton. He congratulated the chairman and his committee upon the result of their labours. There could be no question as to the suitability of Alderman Miles being chosen to perform the ceremony of turning on the current. He laid the stone of the building, and since the laying of the stone he and the committee had been ceaseless in their efforts to make the undertaking a success worthy of the town. He should be wanting in his duty if he did not refer to the admirable services of the electrical engineer, Mr. Rider. He was bound to say that from his introduction to the committee, when he made a most favourable impression, his intelligent devotion to duty and his untiring industry had earned for him the confidence of the committee. He rejoiced in the introduction into the town of lighting by electricity. It was brighter, softer, and more healthy than the ordinary gaslight. When it was introduced into their large workshops, following the example of their excellent Mayor-elect, Alderman Dobson, he felt sure that the healthy condition of the surroundings of the workpeople would be considerably increased. He felt sure they would share with the chairman of the committee in the hope that they would see some results of long, patient, well-directed, and persevering work.

Alderman MILES thanked the Mayor and his excellent committee for the great compliment they had paid him in asking him to perform that important ceremony. That day was an interesting one to him, and also particularly to two other gentlemen who stood on that platform. In the first place, his Worship the Mayor completed his twentieth year of service to the Corporation of Bolton and its inhabitants; that day also witnessed the completion of 20 years' service by the worthy Mayor-elect, Alderman Dobson; and also 20 years of happy service in the interest of the Corporation and the borough generally by himself. It was interesting also from the fact that that was October 31, when they were on the point of saying to the Mayor, "Well done, you good and faithful servant, for the splendid service you have rendered to the borough for the last three years." He was sure they would all join with him most heartily in wishing his Worship and his good lady long life, happiness, prosperity, and good health in the future, knowing that he would be in a position of greater freedom and less responsibility. It was interesting also because it gave him the opportunity of asking them to give a kindly mark of welcome to the Mayor-elect. He felt sure they would all rejoice in the choice which had been made, and they were all expecting great things from Alderman Dobson in the coming year. He hoped after the opportunity they had had of looking round the new works that they were pleased with them. He thought the building was a beautiful one, and although the committee had been determined from the first that they would have everything of the best, they had endeavoured to act wisely and economically, and he hoped they had succeeded. They would be glad to know that in giving out the contracts they had a strong desire to keep as much of the work in the town as possible. In regard to the engines and boilers, to have had these sent into Bolton from other towns would have been like sending coals to Newcastle. As regarded the building contracts, these had as far as possible been given in the town, and when they looked round he hoped they would be ready to say that the committee had been wise in their choice of contractors, and whilst saying this he was glad to have the opportunity of adding that the thanks of the committee, and the borough at large, were due to the contractors, who had striven to put in some of the best work they were capable of for the honour and good of that old town. It had been said that it was a rather anomalous position for the Gas Committee of the Corporation to take in hand the supply of the electric light. He did not agree with this opinion, although it might be contended that gas and electricity were two rival lights. The committee were imbued with one object only. They said, "We are the servants of the ratepayers, and if they desire a supply of the electric light in anything like reasonable quantities, their demands shall be satisfied," and acting on that principle the committee had tried to satisfy their demands as well as they could. They were determined that each concern should stand on its own individual responsibility, and if they had requisitions from customers in the borough for electric light, they would only be too happy to supply it. There were many places where the electric light was far more suitable than gas, and he thought those who adopted it would find a saving in many respects. He then paid a tribute to the zeal and energy displayed by the committee and the electrical engineer (Mr. Rider). He hoped the works would be a success. It would be idle to expect the concern to pay the first year, but another town, rather larger than Bolton, which commenced seven months ago with 1,000 8-c.p. lamps, expected to make a profit the second year. They at Bolton had started with 3,500 8-c.p. lamps, which he was sure would be acknowledged to be a splendid start. They did not want to make any great profit out of it, but in the future he felt sure it would become one of the great profit-making departments of the Corporation.

Councillor W. COOPER was then called upon to speak, and in doing so he said he deemed it no slight privilege to take a small part in the inauguration of a system of electricity for his native town. He was sure the energy displayed by the Gas Committee would be amply repaid. Electricity could do many things—it could cook them a chop, mature their wine, clear their sewage, and drive their trams.

Councillor HORROCKS followed, and alluded to the establishment of the gasworks, and now they were there to inaugurate a new scheme which he believed had a greater future than had the gas.

Alderman DOBSON said that from experiments made at his own works electric lighting was found to be much healthier to use in close-confined rooms than ordinary gas might be. He hoped that would be the universal experience of the town. It would save also in the effect on pictures and articles of furniture, there would not be the same amount of dust and dirt, and everything would last longer. He wished every success to the undertaking.

The MAYOR then presented to Alderman Miles a silver key, commemorative of the occasion, bearing a suitable inscription on one side and the borough arms in enamel on the other, and which was to turn on the light.

Alderman MILES, on receiving it, said it was an unexpected proof of the goodwill of his colleagues, and he tendered his hearty thanks. The engines were set in motion, after which he switched on the light amid great applause.

Subsequently, at the invitation of Alderman Miles, J.P., and the members of the Lighting Committee, a banquet was given in the Mayor's Banqueting-room at the Town Hall, when nearly 100 guests partook of their hospitality. Further speeches were made relating to the new departure, and judging from the remarks at the opening ceremony and at the banquet, the success of the Bolton station ought to be assured. We wish it every prosperity.

Kendal.—The Town Council have had on their minutes an application by the directors of the Windermere and District Electricity Supply Company, Limited, with regard to supplying electrical energy for use within the borough. The committee recommended that having regard to the absence of demand for electricity in the borough and to the fact that in the opinion of the Council it was desirable when such a demand arose that the Corporation themselves shall supply it, the Council be advised not to assent to the application. The Town Clerk stated that the company would wish to know the decision of the Council as the matter was urgent. Councillor Hargreaves was surprised the committee should say there was no demand for electric lighting. Councillor McKay said there were members who would do their best to oppose it. Councillor Jefferys thought they might get it from the company upon what terms they would be willing to hand over the lighting to the Corporation if desired at some future time. Councillor Monkhouse did not see the necessity of their going cap in hand to the company. Councillor McKay asked if the Gas and Water Committee were serious in objecting to the company? If it was a foregone conclusion that they did not wish to have anything to do with the lighting, it would be better to say so. They had had an offer made, and they themselves could never produce power so cheaply as it was offered to them. Councillor Cozens-Hardy suggested that they should have the representatives of the company present, and see what they were ready to offer. The Town Clerk said it ought to come voluntarily from them. The question was whether they would give the representatives the opportunity of meeting them and discussing the matter. Would Mr. Jefferys or any other gentleman in some informal way get their proposals in writing? After some few remarks, Councillor Jefferys said there would be no harm in asking them what they would do. He thought the committee had shown their hands as to the grounds on which any opposition might be raised. They had no authority from the Corporation Councillor McKay: And then to say that there was no demand! Alderman T. Wilson moved the adoption of the minutes. Councillor W. B. Thompson ultimately moved that the Corporation hear a representative, which was seconded and carried, the matter to come before the whole Corporation in committee.

ELECTRIC TRACTION, WITH SPECIAL REFERENCE TO THE INSTALLATION OF ELEVATED CONDUCTORS.*

BY ROBERT W. BLACKWELL, FOREIGN MEMBER, AND PHILIP DAWSON, ASSOCIATE.

In conversation with Mr. Wilkinson a few days ago the suggestion was made that some supplementary memoranda relating to electric tramway practice—collected during the past six months, which we have passed in studying construction on the principal American lines, and in visiting the late large continental installations—might meet with your acceptance, and it was also thought that an exhibition of apparatus employed in erecting and working elevated conductor lines would be of interest at this juncture.

The marvellously rapid and successful introduction of electric traction in the United States is now an old story. That 600 electric tramways are there operating nearly 9,000 miles of track and 20,000 cars—that nearly three-fourths of the tramway movement of the country is electrical—that £45,000,000 is there invested in electric tramways, and that this tremendous result has been, to all intents and purposes, effected within five years, cannot but appeal pleasantly to the electrical engineer. Germany, France, Belgium, Austria, Switzerland, are already investing millions in electric traction, and there seems every reason to believe that England will shortly join the march of progress.

Probably no practical point in electric traction was less understood a few years ago than "rail-bonding," and a few words may be added to what has been said on that subject. Its importance has but recently been appreciated, and it is of first importance. It may be taken that the bonds connecting rails should be, as nearly as possible, of the same current capacity as the metals themselves. If a 70lb. rail be used, the sectional area of copper bonds should be as nearly as possible seven-sixths of a square inch, the ordinary steel rail having approximately one-sixth as much conductivity as commercially pure copper. This would exceed nine No. 0 copper wires.

When electric roads were first constructed a No. 4 galvanised iron wire was considered sufficient.

The contact surface of bond and rail should be as large as possible. With heavy bonding and insulated return-circuit feeders the danger of corroding gas and water pipes (a danger that has been greatly and unnecessarily exaggerated) is practically nil. The Toronto, Baltimore, Salt Lake City, and many other systems may be cited in support of this statement. In cities earlier equipped, where the lightest of rail bonds and return feeders were employed and very heavy current dealt with, serious results undoubtedly ensued, as at Boston, where electric traction was first installed on a large scale. By the use of modern appliances the trouble there has almost ceased to exist. The tramway company employs special workmen to accompany gas and water construction gangs, and to connect all water and gas pipes laid in the neighbourhood of the power-house to heavy bare copper cables returning to the stations. It must, however, be borne in mind that in that city an approximate total of 13,000 e.h.p. has to be dealt with by the three power stations of the West End Street Railway Company. The following are the figures of January 27, 1894, on which day 577 cars and 71 snow-ploughs were running:

Stations.	Hours run.	Mean current for the day.	Maximum current.
Aleston	16	1,203 amps.	1,580 amps.
Cambridge.....	18	4,088 ,, ...	5,425 ,,
Central	24	12,706 ,, ...	14 400 ,,

The average monthly car mileage of this line in 1893 was 1,325,000 miles.

Prof. Jackson, of the University of Wisconsin, has found by experiment that the chemical composition of the soil has a great influence on corrosion. The most favourable to it, and having the smallest resistance, is that in which there is the greatest proportion of chlorides. Nitrates come next, and sulphates last. If, after all ordinary precautions are taken, corrosion still continues, bare copper cables are connected to the negative terminal of the generators at the switchboard, and to all pipes in the neighbourhood of the station. So far as possible the use of earth for the return circuit should be avoided. In conversation lately with Mr. Sprague, he laid great stress upon the advisability of laying the rails upon good stone ballast, and coating all bonds and connections with insulating and preservative compound.

The practice of laying bare copper wires along the whole length of the track, once regarded as indispensable, is now practically abandoned. It has been found that wire so laid rapidly deteriorates and wastes away. All the copper is put into the bonds, the rails are cross-connected approximately every 90ft., and where the volume of current exceeds the economical carrying capacity of the bonded rails insulated return-circuit conductors are employed. A number of rail bonds of approved make are on the table. It is interesting to compare them with this galvanised iron-wire bond of a few years ago. This "Brooklyn" rail bond, as its name implies, has been extensively used in that city. It is a simple strip of copper, so bent as to provide for expansion and contraction. A drive-fit tapered iron rivet at either end holds it to the rails. This "West End" bond is largely employed by the Boston tramways. An iron taper is brazed on to the copper wire at the points where the bond is driven through the web of the rails, and a soldering sleeve connects the free ends of the wire. This "vail" bond is composed of flexible stranded copper cable, welded into heavy terminals, which are provided with copper riveting projections to be forced through the web. This "Chicago" rail bond is more elaborate and effective. The tubular terminals, with slotted ends, are passed through the rail and the tapering drift pins thoroughly driven home, so as to swage or swell the terminals to completely fill the space. It must be noted that the enlarged terminals are of sufficient diameter to avoid any choking of the current as it passes from the rail into the bond. As has been before said, the contact between rail and bond should be as near as possible seven times the sectional area of a bond wire sufficient to carry the given current. The sections shown exhibit the construction very fully. While the solid copper bond possesses all the flexibility found to be necessary, it is made, when desired, with flexible stranded copper cable between the terminals. Mr. Wilkinson has fully described and illustrated other types of bonds, to which it is unnecessary to again refer.

Whether electric welding will eventually take the place of all bonding is still an undecided question. It has not yet stood the test of practical use on a large scale for a sufficiently long period to pronounce an opinion. When first introduced in Boston it was not successful, many rails breaking near the joint after some months' use. The process has since been improved, and a trial section of line was in course of being welded when the "West End" Street Railway was visited last June. Seven miles of welded track have given satisfaction for some months in St. Louis. Over 100 miles are now being welded in Brooklyn, and the result of this trial will demonstrate, after a year or two, the value of welding. At present it takes from 10 to 15 minutes to makes a welded joint, and, on an average, a current of about 250 amperes at 550 volts is necessary, which is transformed into an alternating current at two to three volts pressure. Approximately, each joint costs 12s. to 15s. It is said that the pioneer company in electrically welding rails has already invested over £120,000 in experiments. It is worth mentioning that modern American practice is to butt the rails, allowing nothing for expansion, wherever the streets are paved. The result is a nearly perfect joint. With heavy cars, having at least four to five tons load on each axle, this is of the highest importance. A number of sections of standard American tramway rails are shown, and you will see from them that the highway authorities there are not quite so strict as they are in England, and allow of the use of a rail which presents much less obstruction to the easy running of a tramcar wheel.

Mr. Wilkinson refers to the possible adoption of the three-wire system for electric tramways. That system has been in satisfactory use in Portland, Oregon, for the past four years. Compound-wound generators, working at 500 volts without load, and 550 volts with full load, are used. The success of this system depends upon the load of the various sections being nearly balanced. At Milwaukee, where local conditions did not allow of proper balancing, the system was tried, and given up as a failure. The three-wire system was introduced at Portland because the generating station was three miles away from the nearest point of the line, and the cost of feeders would have been necessarily heavy. By the three-wire system 1,100 volts could be used, −550 and +550, between each two sections of trolley wire. The rails were connected to the neutral terminal at the switchboard. The average load on this station is 1,500 h.p. It is located near a huge lumber-mill, and the fuel is carried by automatic conveyers directly from the waste lumber-yard into the furnace. Several tramways derive their power from this station at a cost of about 25s. per horse-power month, 18 hours' daily work. Thomson wattmeters register the current used. The station pays about 40s. a day for its supply of fuel.

The enormous carrying power of an electric tramway at a pinch is an interesting feature. The following figures, given by Mr. Bowen, of the Chicago City Street Railway Company, show the work done by his electric line on "Chicago Day" at the World's Fair: 51 double-motor cars, 10 single-motor cars, and 73 trail cars were in operation over 26 miles of track. During the day 208,575 passengers were carried, and 11,271 car miles run. The maximum output at the power-house was 17,000 amperes, and the average for 20 hours about 1,050. The minimum current registered was 750 amperes, and the average station pressure 540 volts. The ratio of expenses to receipts on this line is 40 per cent.

The following figures we have already published in a communication to *Engineering*. They are, however, sufficiently

* Paper read before the Institution of Electrical Engineers last night.

Miles electrically equipped	—	—	65·46	81·23	148 04	182·50 (e)
Number of horse cars	1,584	1,794	1,694	1,662	1,226	826
Number of electric cars	—	47	337	469 (a)	1,028	1,346 (f)
Total revenue miles run	15,431,758	16,573,831	17,665,360	17 462,572 (b)	17,498 660 (c)	18,669,809 (d)
Electric revenue miles	—	—	—	4,588 186	9,622,000	14,189,054
Percentage of expenses to earnings	82	82	77	74·4	70·8	68
Investment in electric dols.	—	412,600	1,510,321	—	5,752,694	7,608,069

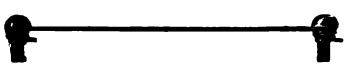
(a) The long cars introduced at this time, and now almost exclusively used on the company's electric lines, are almost twice the size of the regular two-horse car.

(b) Electric mileage ..... 26·27 per cent. Horse mileage ..... 73·73 per cent.
(c) ,, ,, ... 48·63 ,, ,, ,, ... 51·37 ,,
(d) ,, ,, ... 76 17 ,, ,, ,, ... 21·83 ,,

(e) And 25 additional miles partially electrically equipped.
(f) And 24 electric snow-ploughs.

interesting to be placed before you. The largest electric tramway equipment in the world is that of the West End Street Railway, in Boston, U.S.A. Its adoption of electrical motive power practically established the economic value of that method of operation. The figures extracted from its annual reports are shown in Table A.

Attention is specially directed to the decrease in percentage of working costs to gross receipts, which has varied almost directly in proportion to the introduction of electric plant. This reduction has been made notwithstanding the fact that the additional investment required for the introduction of electric plant had to be provided for, and that such part of the company's former plant as was rendered useless, or disposed of at a



Old-style Railbond.

The Brooklyn Railbond.

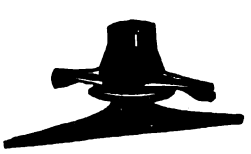
loss, had to be written off. A comparison between the tramways of London (population, 4,306,411 in 1893) and Boston (population, 417,720 in 1890) is interesting:

	London.	Boston.
Miles of street operated	125§	—
,, single track	250 approx.	268½
Number of cars	1,080 (a)	2 172
Car miles run	21,924,290 (b)	18,669,809
Total working expenses	£885 967	£910,147
,, receipts	£1,070,578	£1,338,515
Net receipts	£184,611	£428,368
Percentage of expenses to receipts	82·7 (c)	68
Total capital invested	£3,533,177	£4,435,000
Rate of interest paid on ordinary shares	3·32 per cent.	9 per cent.

(a) London uses top-seat cars, Boston does not. Boston has to keep a double set of cars—open for summer, closed for winter. (b) London has the greater number of car miles run. The majority of Boston cars are much larger than the London ones. (c) Boston investment includes £1,500,000 spent during the past five years on re-equipping electrically.

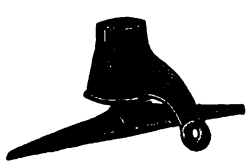
If London's percentage of expenses to receipts could be reduced from the present 82·7 to 70 per cent., net receipts would be increased to £321,174; if to 60 per cent., net receipts would be £428,231. It is almost unnecessary to call attention to the fact that the cost of material and labour involved in the re-equipment electrically of a tramway is much higher in America than in England.

Old-style Trolley Wire Hanger.



W. E. Straight Line Insulator.

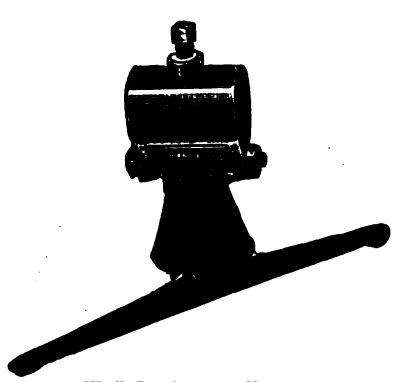
In the early days of electric traction no greater annoyances fell to the lot of the much-tried tramway constructor than those which seemed inseparably connected with the suspension and effective insulation of the conducting wire. No material was obtainable possessing the happy combination of strength, durability, and high insulation with inconspicuousness; interchangeability of parts was unknown, and unsightly, rough-and-ready expedients were used wherever difficulties in erection were encountered. From 1884 to 1889 no insulator better than paraffined wood or porcelain could be obtained. This is the best device the Bentley-Knight Electric Railway Company could evolve to support a bar copper conductor in its conduit system laid in Boston in 1888. As you will see, it is composed of a block of porcelain leaded into a malleable iron holder, and having a brass support for the conductor leaded into it. All of the earlier elevated conductor lines were dependent for their insulation upon the wooden poles by which they were supported, and in wet weather the resultant leakage was a very serious factor. With the introduction of iron poles, and the development of motors and power plant, something better and more permanent became a necessity. The wide extension of electric traction is largely due to the enterprise of independent manufacturers, who, seeing a great and



W. E. Single Pull-off.

W. E. Double Pull-off.

growing need, undertook the elaboration of a system of electric tramway supplies to meet the demand, and relieved the electrical companies of constant consideration of the details necessary for safe and economical transmission of current from power-house to car motor. The taut and workmanlike overhead line of to-day, in erecting which the lineman has had at hand a compact and appropriate device for every insulating or supporting point, differs widely from the unsightly webs which were the rule in earlier years. Your attention is called to the various appliances on the table. They fairly represent the best known and most widely used apparatus. You will note the strong external resemblance between the various makes wherever an appliance for a specific purpose is in question. We will not go into the question as to whether any one insulating material has greater merit than another. The specimens shown include several distinct makes of homogeneous and fibrous insulating substances, the composition of which is a manufacturers' secret; and also insulators of compressed mica, and



W. E. Bracket Arm Hanger.

of solid sheet mica ingeniously compressed between metallic parts, and supplemented externally by a special insulating compound.

Of that important factor, the trolley wire itself, little need be said. The universal American practice is to employ No. 0 hard-drawn copper. Many continental lines have employed lighter trolley wire—in some instances as small as 6mm.—and some use larger. It may be taken, however, that No. 0 is the size that gives the best all-round results. Phosphor bronze is of doubtful utility as a substitute for hard-drawn copper, the increased tensile strength being more than overbalanced by the reduction in conductivity. The manufacturer of the trolley wire should guarantee 98 per cent. conductivity or better, and perfect joints, and should deliver wound on special reels in mile lengths. Good running and a low rate of depreciation

Digitized by Google

depend largely upon the exactitude with which the trolley wire follows the line of the metals, and pains taken to ensure a smooth and even path for the trolley wheel are always well repaid.

In the selection of the line of appliances to be used the nature and needs of the individual road must be borne in mind. For a suburban line and light traffic, where economy in first cost is a first requirement, this "Ætna A type" insulator serves the purpose well. You will see that the series in this type includes a straight line insulator, single and double pull-off for curves, and a bracket arm hanger. The construction is shown in this section.

In this type, the homogeneous mass of insulating material, while still in a plastic state, is forced under heavy pressure into a casting provided with internal flanges to hold it securely in place, and external points to which the span or strain wires may be attached. The threaded thimble is moulded into the insulating material at the same time. The threads are made to take 7-16in. or §in. screw studs, according to the strain they are to sustain. The metallic parts, which partially protect the insulating substance, are of either bronze or malleable iron. In this type the strain and weight of the trolley wire is taken by the insulating material itself. This is the type of insulated suspension employed by the South Staffordshire, Douglas and Laxey, and Guernsey lines, and many continental and colonial roads.

To supply the needs of tramways where constant and heavy traffic is to be expected, and where security to the service is of far more importance than small economies in first cost, the "West End" type of insulating material has been evolved. This series is more elaborate than the former, comprising a straight line insulator, single and double pull-off, bracket arm hanger and bridge, spring bridge, and car-house insulators. These are far more substantial than those first described. The essential difference in construction is that the insulation is wholly protected from injury from exposure or chance blows, by a metallic skirt, and that no part of the strain comes upon the insulating material itself, the load and strain being wholly taken under all circumstances by the heavy metallic parts of bronze or malleable iron. The insulating part is a bronze or steel bolt, heavily coated under pressure with non-conducting material, the head of which fits closely into a recess at the top of the protecting casting, and is firmly held there by a screw cap. These bolts are interchangeable throughout, and can be slipped in or out at any time. When it is desired to bring a feeder into the line the insulating bolt is slipped out and a metallic "feeder plug" of exactly the same size takes its place, this throwing the whole hanger into circuit and allowing an insulated feeder wire to be attached to it in exactly the same way as an ordinary span wire would be. A special tool is used in putting up "West End" straight line hangers, and much facilitates the labour of erection. The casting is held in the fork at the top of the tool. The span wire fits into the groove of the wheel, and a single movement of the lever snaps the wire into position. By the use of this "West End" type of apparatus, the span wires can be erected, and the castings inserted at the fixed points of suspension, before the insulating material is brought on the line. Ears can be soldered to the trolley wire and attached to the insulator afterwards, and there is a minimum of leakage through moisture. As an illustration of the care taken to supply each need, I would call your attention to the "spring bridge" insulator, used under bridges and elevated railway structures and in tunnels. As the fixture is of necessity rigidly attached to the structure above the line, a yielding support is provided in order that the trolley wheel, at high speed, may not strike a point without flexibility and have a tendency to jump the wire. The spring is protected by a galvanised iron case, and the insulating bolt within has a fluted metal covering, which preserves the insulation from injury by chafing, and prevents the bolt turning.

The use of high-class line material greatly facilitates both construction and operation, and in no part of the equipment can a little additional expense be incurred with such good reason. Note how carefully the makers of both the above types of apparatus endeavour to bring span wire and trolley wire close together. Earlier styles did not possess this virtue, the span wire being led over the top of the insulator. Experience quickly showed that it was an error to separate span and trolley wire more than absolutely necessary. To connect the trolley wire with its insulated supports ears or clips are used, of which a number of varieties are on the table. For efficiency, durability, and smooth running nothing quite equals an ear soldered to the trolley wire, and soldered ears are almost indispensable at curves or points of heavy strain. However, it takes skilled labour and quite one-third longer in time to erect a line using soldered ears throughout. I would especially call to your attention the fact that the blow-pipe must not be used in erecting a trolley wire with soldered ears, but instead heavy grooved soldering irons, like the one shown, must be employed. The use of the blow-pipe softens the wire, and renders it liable to break. A trolley wire must be "anchored" at least every mile of straight line, and always at either end of every curve. Special ears are provided to which the anchor wires can be readily attached. Special ears are also used for jointing together lengths of trolley wire. Joints should always be made at fixed points of support. A properly-soldered combination anchor and splicing ear is on the table. Other ears are used for points where it is desired to make connection with feeders. Trolley wire soldered ears are made 7in., 9in., or 15in. long. Samples are shown of the regular soldering and span wire work of the linemen of the Boston tramways.

The perfect mechanical ear has not yet been evolved, although improvements are constantly being made. Several types are on the table. The difficulty is that all mechanical ears interfere more or less with the smooth under surface of the trolley wire, and any obstruction, however slight, to the passage of the wheel is a disadvantage. This "Badger" mechanical ear is simple and effective. It is composed of two interlocking plates of malleable iron and bronze, which, when placed together, leave a groove into which the trolley wire is clamped by the wedge-shaped stud of the insulator being forced into the jaws formed by the upper portion of the two plates. A pin through the stud hold the ear and stud together. Another exhibit shows the same clamping principle applied to a hinged ear, a screw stud set in the insulator being substituted for the wedge, and the pin being dispensed with. Another type shows the clamps held together by screws. The "Anderson" mechanical ear is composed of a bronze casting grooved along its lower surface to fit the trolley wire, and a plate of hard-rolled copper bent to fit over the trolley wire, and furnished with eyes which close over slotted projections on the casting. The whole is bound together by forcing the eyes into the slots by the small screw-bolts at the top of the casting. A special clamp is used to force the copper plate into position and hold it until the screws have been set up. The number of mechanical clips is legion, but none are quite up to the soldered ear. Mechanical ears are good or bad in proportion to the extent to which they interfere with the smooth running of the trolley wheel and necessitate bending of the wire. The latter is always a mistake, because, if it happens that the position of an ear has to be changed, a kink is left in the wire. It is also an error, frequently made in early days, to allow any play or joint between the insulator and the ear.

By the courtesy of Mr. I. Everson Winslow, we are enabled to exhibit to you a series of the Thomson-Houston insulated suspensions employed by him in the erection of the elevated conductors for the Roundhay tramway line at Leeds. In the straight line insulator, and single and double pull-offs, the strain is taken by malleable iron or bronze castings, which spread out sufficiently to protect the insulation from accidental blows from the trolley, and to form a water-shed. A cap of insulating material, from which projects a screw stud, fits closely over the top of the casting, and the recess beneath receives a cone of the same insulating substance, through the centre of which the stud passes. When the ear is screwed up on the stud the whole is bound tightly together. Some of the insulators shown have been in regular use at Leeds for three years and show no sign of deterioration. A bracket arm insulator, anchor ear, splicing ear, and an aerial frog, as used at Leeds, are also before you. Earlier Thomson-Houston forms, showing porcelain insulation instead of the material now used, are also exhibited.

Dr. Edward Hopkinson has been kind enough to send us this insulator and mechanical ear used by the Isle of Man Tramways. It is somewhat similar to the "Anderson" ear already described, but of stronger construction. It must be borne in mind that the Douglas and Laxey line employs a sliding contact, and not a wheel. We have been unable to obtain one of the Douglas collectors for exhibition to you, as no spare ones were at hand. Double insulation is an essential feature of first-class overhead line work. This is effected by supplementing the insulated trolley-wire supports by an additional insulator at the pole-head. The "Brooklyn" strain insulator and turnbuckle combined is the best device for this purpose. Aside from its insulating qualities, a pair of the smaller size shown will take up 6in. of slack in the span wire. This is extremely useful in adjusting tension when the span wires have become stretched by constant use. The larger size is adapted for terminals, and for corner poles to which a number of curve pull-off wires are carried. The "King" insulated turnbuckle is a device of similar nature, and strain insulators of the various types are also frequently used. All globe and strain insulators, by the way, are constructed so that, should their insulation be entirely destroyed, their interior metallic parts would interlock and prevent the line falling. Sections and parts of insulators by a number of makers are on the table.

In cases where the trolley wire is supported by bracket arms, double insulation is obtained by the use of a tube of insulating material within the sleeve of the bracket arm hanger. In this connection we would warn you against the frequent mistake of fixing bracket arm insulators to predetermined points of the bracket. A sleeve which will slide along the projecting arm easily should always be used, as nothing but observation of the trolley wheel as it passes under each bracket can determine the exact point at which the hanger can be most advisably fixed. This feature is also apparent in the Thomson-Houston type of

Digitized by Google

bracket arm hanger from the Leeds line. In this appliance double insulation is obtained by washers and tubes of insulating material, which prevent metallic contact between the upper casting in which the sleeve is formed and the lower casting from which the ear depends. A trolley wire of any considerable length should always be divided up into sections, so that an accident could not cause the whole line to be thrown out of service. Several types of section insulators are before you. Connection between the two sections of trolley wire is made or broken through a switch contained in a box on the nearest pole. The earlier type shown, made of brass sections insulated from each other by mica, is somewhat clumsy. You will note that the insulation of the two later forms is effected by bolts similar to those used in the "West End" hangers, and that the latest and most improved type has the great advantage of being "straight under-running," allowing the trolley wheel to pass under it without the slightest "dip." This device is strong and durable. The wooden piece between the terminals is renewable, and can be changed while on the line. A convenient clamping device renders it possible to leave enough trolley wire coiled on top of the section insulator to allow of its being let out to repair the line in case of a break.

Another part of this combination clamp holds the feed wire in such a way as to obviate the necessity of stripping the insulation from the wire, except at the part held by the clamp. By this arrangement the feed wire is left insulated from the poles to the section insulators, and between the lines (where there is a double track). A number of frogs and crossings are on the table, and you can see how greatly the later types are improved over those used a year or two ago. All the newest styles have the "straight under-running" feature, and require no solder, the trolley wire being clamped into the casting. You see that in all cases the trolley wire is carried over the casting, so that the excessive wear at these points is taken by the heavy metallic flanges, and not by the conductor. Right and left hand, "Y," and three-way frogs are used, and they are insulated and supported by frog pull-offs. The operation of right and acute angle crossings is easily understood, and an insulated crossing is employed whenever one trolley wire crosses another from which it must be insulated. The wire-stretching machine shown is an extremely useful tool in all cases where it is necessary to take the tension off the trolley wire, as in splicing, or inserting switches, frogs, etc. Several styles of feeder insulators are shown. The best has a metallic yoke, into which the feeder cable is laid and firmly held by a screw cap. This greatly economises labour in the erection of an aerial feed wire. Where guard wires are used, they are insulated by small porcelain insulators. The utility of guard wires is extremely doubtful, and many lines have discarded them. On the Continent, a strip of wood is often attached to the upper side of the trolley wire, whenever any danger from falling telegraph or telephone wires is apprehended. A number of special tools and appliances are on the table, to which we will not refer at length. They are self-explanatory, and we should be glad to have you examine them.

The trolley itself next claims our attention. As in the case of all electric tramway supplies, the earlier types were comparatively clumsy, and the old form of trolley base occupied a great deal too much room on the roof of the car. It is shown in an illustration. The latest "Boston pivotal" type is fixed to the table. You note how easily the trolley moves in every direction. This base is of simple construction—neat, compact, and designed to allow of passing under low bridges. Experience has proved it to be smooth-running, easy of adjustment, strong, and durable. It lies close to roof of car, and can be swung around to change direction. With pole laid down flat, the highest point on the base is but 6in. above the roof. To avoid overtaxing the springs so that they will set or break, a very large safety factor is allowed. A special construction ensures an even pressure of the wheel against the trolley wire in the different positions. This trolley received the highest award at the World's Columbian Exposition at Chicago. The steel trolley

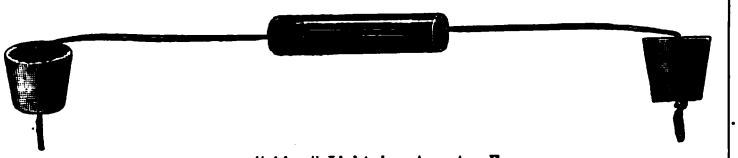
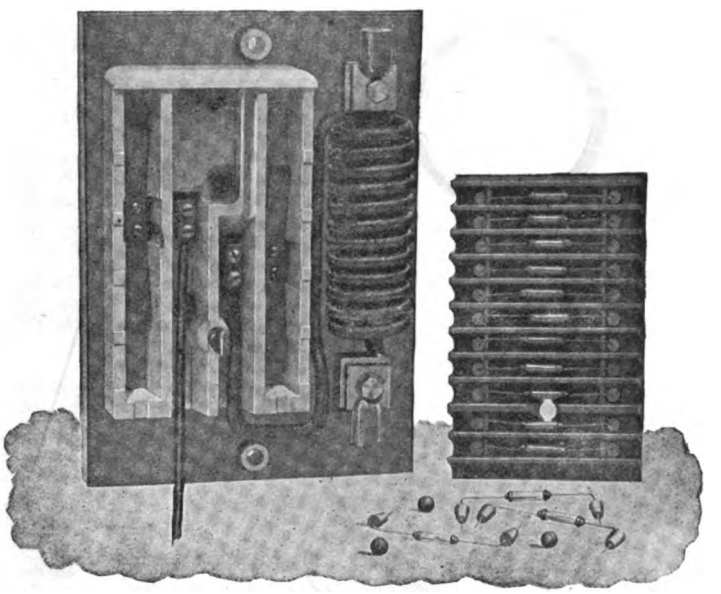
pole is of one piece of steel with a continuous taper, and without joints, shoulders, or other points of weakness. It is light, strong, and stiff. If bent by an accident, it can be straightened cold. The steel trolley fork is of a new pattern, tapering in



"Ajax" Lightning Arrester Fuse.

form, of sheet steel, light and strong, provided with phosphor-bronze contact springs and washers, which have proved far more durable than those of copper. The spindle is of hardened steel. We are again indebted to Mr. Winslow for the loan of



"Ajax" Lightning Arrester for Motor Car (cover removed).

the Thomson-Houston trolley base, which is also fixed to the table. Its operation is practically the same as the other pivotal trolley, but you will see that the construction, especially as regards the arrangement of springs, is somewhat different.

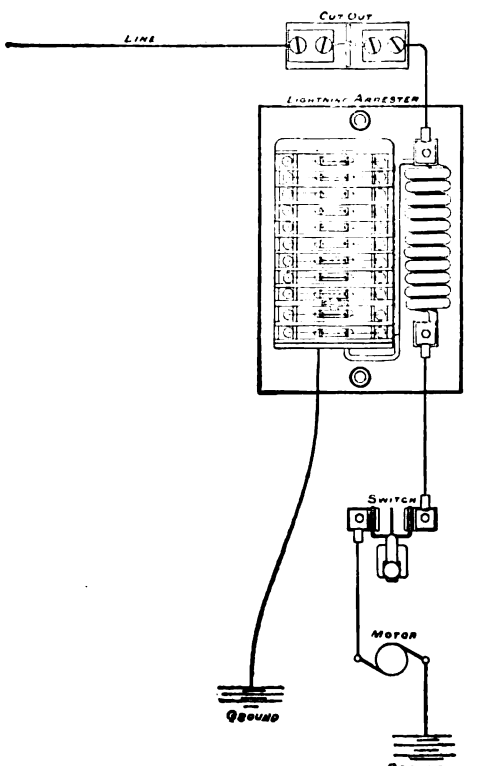


Diagram showing Connections of "Ajax" Motor Lightning Arrester.

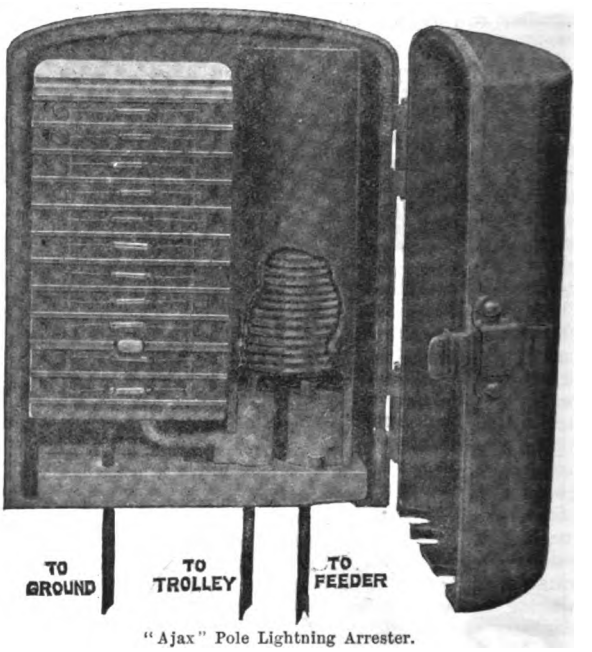
Great attention has been paid to the development of a first-class trolley wheel, and several types are exhibited, showing the evolution of the present approved type now universally used. This is the earlier form of wheel, made, as you will see, of a single bronze casting, and with the V-shaped groove then considered best. A substantial improvement was made upon the earlier form in the "Boston" wheel before you. In this a very substantial hub was provided to take the spindle. Iron guard plates were riveted on either side to prevent the trolley jumping the wire. The wear was taken by a contact ring which could be removed and replaced as needed, but at considerable expenditure of time and trouble. You will see how the shape of the groove has changed.

Spoked wheels are now universally used, like this "West End" wheel. These are made of a single bronze casting, having a wide and highly-polished groove, and being furnished with either graphite or self-oiling bushings to receive the spindle. When the older form of brass trolley wheel is used, the flanged drops off when the groove which receives the trolley wire wears through to the outside. By using the "spoked" trolley wheel this difficulty is entirely obviated by a simple and effective



"Ajax" Pole Lightning Arrester.

method of construction. The ribs serve to hold the flange in position after the sparking of the wheel indicates that it is worn through, and therefore should be discarded. This warning is timely, for the wheel may be used after the flange is cut through

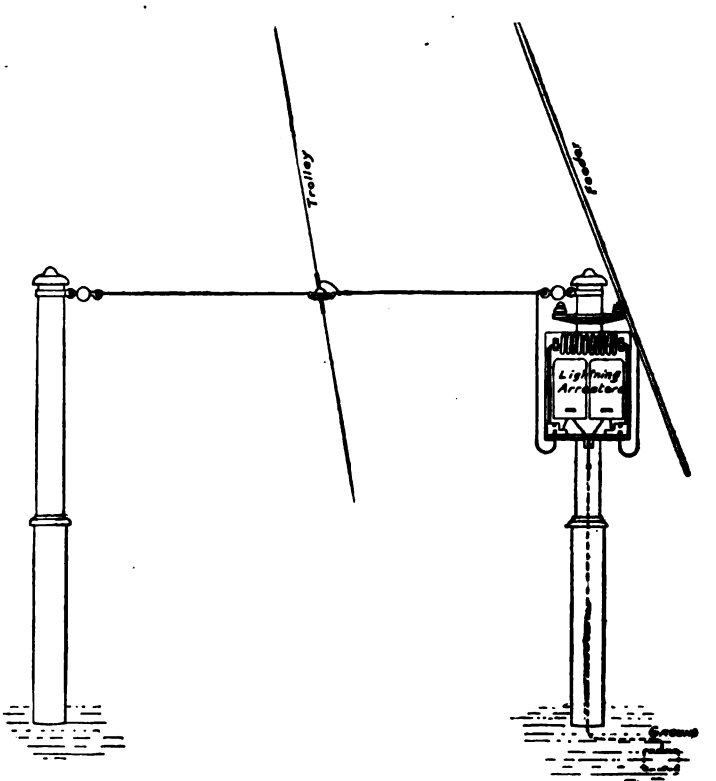


Diagram showing Connections of "Ajax" Pole Lightning Arrester.

by the trolley wire long enough to get to the car-house, where a new wheel can be put in. With the old form of brass wheel, when the flange wore through and dropped off, the car was disabled, and had to be pulled to the car-house or removed from the track. If this breakdown occurs in a crowded thoroughfare, or in an out-of-the-way place where it is not easy to obtain

Digitized by Google

assistance, as is often the case, the awkwardness of the situation and the annoyance resulting from it are obviously great. You can see how thoroughly these ribs fulfil their mission by inspecting this "West End" wheel, which has run about 4,000 miles upon an English line. A great deal of care has lately been devoted to the elaboration of a trolley more suitable for use with the English top-seat car than any of the American types shown. We hope to be able to exhibit it, as one is on its way to us as this paper is being written. We regret that we have been unable to secure for exhibition one of the trolleys of the South Staffordshire line.

One of the most interesting appliances to which your attention is directed to-night is this "Ajax" lightning arrester. The rest of the apparatus is merely a support for holding a succession of these fuses, so that one after another is brought into operative position automatically by the action of the current as it consumes each fuse in turn. The fuse consists of two pieces of No. 26 brass wire, each 3in. long, having a single silk insulation, and laid side by side for about 1in., as do consecutive coils in an armature. This 1in. lap of the wires offers abundant surface for the discharge gap, which is formed by the two thicknesses of silk, and amounts to little more than 0·002in. Small pellets of a highly insulating wax secure these wires in the above position, and a small glass tube is hermetically sealed over this part of the fuse to keep the dischargers clean and dry until used. The extreme sensitiveness of this part of the apparatus is made possible by its being called upon to act but once. The soft rubber plugs serve to hold the fuse in the corrugated cover of the arrester, and the bare ends of the wires project through the cover, ready to be brought into contact with the line and ground terminals. This is the type of arrester used for protecting stationary motors or isolated plants. The regular size is made with a 100-ampere coil, having coil and arrester mounted on a marble slab 7⅞in. by 11in. by ⅞in. Pole-boxes are cast iron, asbestos lined, and so constructed as to exclude rain. This is the more general form of pole arrester. In this the choke coil is contained in the arrester-box; but it may be made by turning the insulated span wire on itself a sufficient number of times to make the choke coil, thus making a cheaper construction and a smaller pole-box. The warming of tramway cars by means of electric heaters is now universal in America wherever the climate is at all cold. This is the simplest form, of which any number desired may be screwed under the seats of a car. More elaborate forms are also made.

A word may be said in support of what Mr. Wilkinson has said as regards the appearance of overhead conductors. Undoubtedly some aerial lines have been put up with an utter disregard of appearances, and inexperienced or careless constructors have erected webs of trolley strain and feeder wires which were most obnoxious. This is especially true of many hastily-built American lines, pushed through at high pressure, and at the smallest possible expenditure. Now that the first rush is over, and the tramway operator, the manufacturer, and the contractor have had time to take breath the weight of public and Press criticism has had its effect, and no pains are spared to perfect the entire plant and apparatus. A carefully designed and erected line, with sub-surface feeders, handsome poles, etc., has but few objectionable features; and in the great majority of cases public convenience is so greatly enhanced by the overwhelming advantages that closely follow upon the introduction of improved and more rapid transit facilities, that opposition to the extension of a trolley line is almost unknown. The Siemens line at Guernsey, the line that crosses the great piazza on which Milan Cathedral stands, the Brussels, Hamburg, Bremen, and a dozen other continental installations, are European examples of line construction to which no reasonable objection can be urged. The electric tramway has a future as great in Great Britain as elsewhere, and in no other country in the world has it failed to already secure universal acceptance.

The English tramway operators, and the able executive officers of the Tramways Institute of Great Britain and Ireland, are keenly alive to the possibilities that lie in electric traction, and, under most adverse conditions, are doing their best to smooth the path of progress. It remains with you, gentlemen, to supplement their endeavours, and to do your best to stimulate and encourage the growth of public opinion in its favour.

ELECTRIC METER TESTING BY THE LONDON COUNTY COUNCIL.

The Highways Committee of the London County Council reported on Tuesday as follows: "We have had under consideration the question of the fees to be charged for the testing of meters at the Council's electric meter testing station at Cranbourne-street. The Council is no doubt aware that only one meter has as yet received the provisional approval of the Board of Trade as required by the various Acts and orders, but there appears to be a strong desire on the part of both the companies and the consumers for the testing of electric light meters. We are of opinion that, as the Council has competent electricians in its service and every necessary appliance for the purpose, it should meet this demand, and should lay down a scale of fees which may be charged until the arrangements as regards meter-testing shall have been definitely settled. We therefore recommend that until further order fees according to the following scale be charged for the testing of electric light meters by the Council's officials:

For testing single meter of any description up to 50 amperes capacity	10s. 0d.
Ditto of capacity of 50 to 100 amperes	20s. 0d.
Ditto of capacity of 100 to 200 amperes	30s. 0d.
Ditto of capacity of 200 to 400 amperes	40s. 0d.
Ditto of capacity of 400 to 600 amperes	60s. 0d.

For testing meters, delivered at and removed from the testing station free of cost to the Council, any work necessary for adjusting defective meters being charged for extra:

Ferranti Hookham, and all similar meters without shunt coils and not requiring to be fixed for testing, up to 50 amperes capacity, if sent in in batches of not fewer than 10 of the same size and make, each	6s. 6d.
Ditto from 50 to 100 amperes capacity, each	9s. 0d.
Ditto from 100 to 200 amperes capacity, each	12s. 0d.
Shallenberger, Thomson, and similar meters with shunt coils or requiring to be fixed for testing, up to 50 amperes capacity, if sent in in batches of not less than 10 of the same size and make, each	7s. 0d.
Ditto from 50 to 100 amperes capacity, each	10s. 0d.
Ditto from 100 to 200 amperes capacity, each	13s. 0d.
Aron and other meters requiring fixing and synchronising, up to 50 amperes capacity, if sent in in batches of not less than 10 of the same size and make, each	8s. 0d.
Ditto from 50 to 100 amperes capacity, each	12s. 0d.
Ditto from 100 to 200 amperes capacity, each	17s. 6d.

A reduction of 10 per cent. from these prices to be allowed if 20, and of 23 per cent. if 50, meters of the same make and capacity are sent in at the same time.

For examining in position after fixing any single meter within a radius of three miles from Cranbourne-street	2s. 6d.
Ditto any distance from three to six miles	3s. 6d.

In addition to travelling expenses.

For examining in position after fixing, where a number of meters in the same district and within a reasonable distance of each other can be inspected on the same day, £1 for the services of the inspector for the entire day, or 15s. for half a day."

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

St Pancras.—The St. Pancras Vestry invite tenders for works under the following two contracts: (*a*) supplying and laying armoured cable mains; (*b*) extension of underground sub-station building. The drawings can be inspected, and specifications, schedules of quantities, and general conditions can be obtained, at the offices of Prof. Henry Robinson, C.E., 13, Victoria-street, Westminster, on payment of 5s. for each contract. Tenders to be sent to Mr Albert E. Pycraft, chief clerk, Electricity and Public Lighting Department, Vestry Hall, Pancras-road, London, N.W., on or before 22nd inst.

Donnybrook.—Offers are invited for the whole of the electric lighting plant and stores used in the lighting of Donnybrook Fair at the close of the fair, either the whole or in parts as it stands, or erected as complete installations, to suit the requirements of purchasers. The plant consists of one 12-h.p. portable steam-engine; two 160-ampere 100-to-110-volt dynamos; one 45-ampere 100-volt ditto; one 15-ampere 100-volt ditto; six arc lamps 1,000 incandescent ditto; 800 Ediswan bayonet holders; several miles of wires and cables, of various sizes; 400 white silk shades, etc. Apply to the manager, Electrical Installation Company, Limited, on the premises, Donnybrook Fair.

RESULTS OF TENDERS.

Aberdeen.—The following tenders have been received for fitting up the new police offices with the electric light. Mr. John Rust, 224, Union-street, Aberdeen, city architect:

Shirras, Laing, and Co., Aberdeen (accepted)	£143 18 0
New and Mayne, Aberdeen	186 0 0
Faraday Electrical Engineering Company, Limited, Glasgow	265 0 0

For electric lighting of Aberdeen Coffee Company's buildings, Shiprow, Aberdeen. Mr. John Rust, architect:

Northern Electric Supply Company, Cults, Aberdeenshire (accepted)	£94 0 0
Shirras, Laing, and Co., Aberdeen	94 11 0
New and Mayne, Aberdeen	110 0 0
Faraday Electrical Engineering Company, Limited, Glasgow	120 0 0

Digitized by Google

BUSINESS NOTES.

Folkestone.—The parish church has been lighted by electricity.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,861.

Blackburn.—It is anticipated that the central station will be completed by the end of the year.

Great Northern Telegraph Company.—For the month of October the receipts were £27,200.

Windsor.—A provisional order is to be applied for by the Town Council for both Windsor and Eton.

Formoy.—The question of electric lighting is still under the consideration of the Town Commissioners.

Cuba Submarine Telegraph Company.—For the month of October the receipts were £242 more than for the corresponding period.

Eastern Telegraph Company.—The receipts for the month of October were £67,754, as against £61,409 for the corresponding period.

Scarborough.—An account received for lighting the Town Hall by electricity has been referred to the Finance Committee for payment.

Direct Spanish Telegraph Company.—For the month of October the receipts were £2,101, as against £2,121 for the corresponding period.

Dover.—The Town Council have received notice from the electric light company of their intention to extend their mains to Buckland Flour Mills.

Eastern Extension Telegraph Company.—For the month of October the receipts show an increase of £1,141 as compared with the corresponding period.

Montrose.—The Town Council have sanctioned an agreement with the Scottish House-to-House Company for the introduction of a supply of the electric light.

Canterbury.—A correspondent writes to a local paper suggesting that a canvass of the citizens might be adopted with advantage by the Canterbury supporters of electric lighting.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 4th inst. amounted to £884, as compared with £608 in the corresponding week of last year.

Birkdale.—The chairman of the Gas Committee of the Local Board thinks that the town should be provided with the electric light. And so do we. Why not approach the Southport Corporation on the matter?

Mill-Lighting.—Messrs. Lowden Bros., Dundee, have secured the contract for the electric lighting of the Seebpore and Howrah Jute Mills Calcutta. The installation will be similar to that fitted in the Dundee Mills.

Newport Electrical Engineering Company, Limited.—This Company has been registered with a capital of £2,000 to carry on at Newport, Mon, or elsewhere, the business of mechanical engineers in all its branches.

Rotherham.—Complaints have been made at a meeting of the Town Council as to the quality of the gas supplied, and Mr. Jenkins stated that unless some changes were effected, manufacturers would be obliged to introduce electric lighting into their works.

Huddersfield.—Messrs. Pearson Bros., of the Commercial Mills, have already adopted electricity as a means of lighting their premises. In addition, another firm of manufacturers in Slaithwaite have under consideration a similar undertaking, and a third firm may resort to electricity after the winter.

Birmingham.—Subject to the consent of the City Council, the Birmingham Technical School Committee have accepted a tender of the Walsall Electrical Company, Limited, for the installation of the plant, fittings, and appliances for both the lighting and provision of power in the new school, for the sum of £6,375. 18s.

Cardiff.—In the course of a discussion by the members of the Town Council on the subject of the purchase of the tramways, Alderman Carey mentioned that the Blackpool Corporation had recently taken the bull by the horns, and without specially obtained powers had commenced to work the electric tramways

City and South London Railway.—The receipts of the Company for the week ended November 4 were £939, against £874 for the corresponding week of 1893, or an increase of £65. The total receipts for the current period of the present half-year amount to £15,750, as against £14,680 in the corresponding period of 1893, an increase of £1,070.

Chelsea.—Mr. T. W. Higgens, surveyor to the Vestry, reported on Tuesday that the London Electric Supply Corporation had so altered their connections at the Pimlico station that the Chelsea circuit would now be fed separately. The Board of Trade have formally approved of the alteration, and notified their approval to the Chelsea Vestry.

Derby.—The Electric Lighting Committee reported to the Town Council yesterday (Thursday) that the present installation is designed for 7,500 lights, that 7,450 are already attached, and that there are signed applications for 3,000 more. The expenditure is still within the amount granted by the Council (£35,000), but a further grant will be necessary.

Stafford.—The Electric Lighting Committee of the Town Council have reported that the expenses in connection with the laying of the commemoration-stone of the electric supply station amounted to £20. 7s. Alderman W. H. Peach proposed the adoption of the report, stating that the works were proceeding satisfactorily. The report was carried.

Newport (Mon).—Although the lighting of the public streets at Newport by electricity is not likely to be an accomplished fact until January next, the supply of electricity from the Corporation station to private premises will, according to arrangement, commence in the third week of the present month. The demand at Newport has been encouragingly large on the part of private consumers.

Swansea.—A special meeting of the Electric Lighting Committee of the Swansea Corporation has been held for the purpose of receiving a report from a sub-committee which recently visited Liverpool, Warrington, Oldham, and Leeds with the object of obtaining information as to the question of lighting the town by electricity. The committee decided to invite Mr. Manville, electrical engineer, to visit the town, with a view of advising on the scheme.

Birkdale.—In moving the adoption of the minutes of the Gas Committee of the Local Board, Mr. G. Atherton complained of the quality of the gas supplied to the district. He said that when they did not require the gas to the extent they did at the present time, the Southport Corporation were able to conform to the stipulation of the Act of Parliament. He hoped that when the new district council was formed it would consider the advisability of adopting the electric light.

Sheffield.—The Sheffield Electric Light and Power Company are fixing the electric light at the new Assay Offices, at the new rooms of the Literary and Philosophical Society, and of the Sheffield Society of Architects and Surveyors; also at the Church Institute; at the Weston Park Museum; at Oakbrook, for Mr. W. S. Laycock; at Elmfield, for Mr. George Senior; and at Mr. Hides's new premises in the Shambles. These are in addition to a large number of other important installations that are nearly ready for the current to be turned on.

Colliery Lighting.—Messrs. Ernest Scott and Mountain, Newcastle on-Tyne, have at the present moment in hand an order for the Ashington Coal Company for a dynamo to run 1,000 incandescent lamps of 16 c p., and they have also arranged with the Harton Coal Company, of South Shields, to supply a machine of the same size for the lighting of their Whitburn Colliery. In each case the extensions have been decided upon after lengthy experience with electric lighting, when its many advantages and great economy for colliery work have been fully demonstrated.

Sale of Plant.—Messrs. Fuller, Horsey, Sons, and Cassell will sell by auction at their offices, 11, Billiter-square, E C., on Wednesday, November 28, electric generating plant, comprising two 40 nominal horse-power loco.-type boilers, with super-heaters, by Marshall; three 80-i.h p. Armington-Sims engines; three 60-unit Elwell-Parker shunt-wound dynamos; 52 31-plate "K" type E P.S cells; three ampere-meters, Cardew voltmeter, switchboard, switches, resistance coils, 11in. double leather belts, and other effects. This plant has been in use at Billiter-buildings.

Kingswood.—Mr. Bridges, having alluded to the need of more light being acquired, said he would move at the next meeting of the Local Board, "That, seeing the urgent want of better lighting in populous places in Kingswood, and the easy facility by which it may be obtained either by electricity or gas, our Board be asked to take early means of obtaining the same by putting a light at the opening of Laura-street, New-street, Bright-street, Hanham-road, London-street, Park-road, Tabernacle-road, Johnson's lane, and any other such populous places requiring lighting."

Halifax and Bermuda Cable Company, Limited.—A circular has been issued on behalf of the trustees of the £120,000 4½ per cent. debentures of the Halifax and Bermuda Cable Company, Limited, asking for the assent of the debenture-holders to an application to Parliament during the coming session for a modification of the trust deed. This deed, by an oversight, did not provide for the application of the sinking fund to the redemption of the bonds by drawings or purchases, while unless it is so applied there will be a deficiency of about £30,000 on the maturity of the bonds. Parliament is to be asked to sanction this method of redemption.

Brighton.—Good progress is being made with the new parochial offices, which are to be lighted by electricity. The Works Committee of the Town Council have reported to the Council that at a meeting of the committee, held on October 19, a letter was read from Councillor Evans with reference to the payment of wages to the surveyor's workmen engaged at the electric light station who were suspended in consequence of a dispute between workmen there. The committee resolved that Mr. Evans be informed that the men will be paid. On the motion of Alderman Botting, seconded by Alderman Brigden, the proceedings of this committee were confirmed.

Chelmsford.—Last week the electric light went out. Messrs. Crompton and Co., the contractors, wrote stating that the cause of this serious breakdown was the failure of one of the cables. They had taken immediate steps to remedy the defect, and to prevent any such occurrence in the future. Alderman Duffield said he found four of the incandescent lamps on the Broomfield-road out the other evening, and Councillor Gepp and others spoke of complaints in regard to the lighting from New-street, Cottage-place, Coval, and other roads. It was agreed to place lamps in South-road, Barrack-square, Railway-square-road, Seymour-street, and Wolsey-road.

Digitized by Google

Glasgow.—It is apparent, an Aberdeen paper states, from the action of the Watching and Lighting Committee that electric lighting for street purposes in Glasgow is doomed. The committee has decided upon an extension of the system of street-lighting by incandescent lamps. In a given area electricity was found to cost £78; ordinary gas, £39. 13s. 10d.; and incandescent lamps, exclusive of the initial cost of burners, £17. 3s. 3d. The new Conservative Club has been lighted by electricity by Messrs. D. and G. Graham, of Sauchiehall-street, Glasgow, and for this purpose a gas-engine and dynamo have been installed.

Wolverhampton.—In their annual report the Lighting Committee of the Town Council refer to the acceptance of tenders relative to the introduction of the electric light into the town. The loan for the work was £30,000, and the buildings are now approaching completion. The committee had anticipated that the whole of the works would have been completed and the plant in running order by the end of last September, but regret that circumstances have arisen which have caused some delay. However, no effort will be spared to furnish a supply of electrical energy to any person desiring the same as soon as possible. Up to the present time 37 applications for a supply of electrical energy have been received.

West India and Panama Telegraph Company.—The report for the six months ended June 30 show that the amount to credit of revenue is £40,598, and that expenses have been £24,488, leaving a balance of £16,109, which, with £718 brought forward, makes a total of £16,827. Dividends of 6s. per share are proposed on the first and second preferences, and 6d. per share on the ordinary capital, leaving a balance of £2,850. The traffic receipts for the six months show a decrease of £6,504, due to the continued depression of West India trade. The cost of repairs during the half-year amounted to £11,374. The Danish colonies have renewed their subsidies for five years. The receipts for the two weeks ended October 31 were £10 less than for the corresponding period.

St. Pancras.—The Vestry at their meeting on Wednesday, held under the presidency of the vicar (the Rev. H. L Paget, M.A.), approved of a scheme of the Electricity Committee for supplying the remainder of the parish with the electric light, the commercial success of which has been proved in the south-west district. The estimated ultimate cost of the entire new works is £48,565. The committee were authorised to proceed forthwith with the laying of mains in a large area to be served by the King's-road station, which is rapidly approaching completion. When these works were originally planned in July last it was calculated that the expense would be £28,000, but having regard to the present reduced price of copper it is anticipated that a saving of £6,000 will be effected in the estimate with respect to this material alone.

Appointment Vacant.—The Corporation of Cardiff are about to appoint a practical man able to take full charge of the machinery at the electricity works, Canton, Cardiff, and invite applications for the post. Applicants must be experienced in electrical work and engine fitting, and have had actual experience in the charge of a high-tension alternating system at an electric lighting station. Age not less than 25 nor more than 40 years. Salary £3 per week. Applications, in candidates' own handwriting, stating age, whether married or single, past and present employment, with particulars of experience as above, and accompanied by copies of not more than three recent testimonials, to be delivered at the office of Mr. J. L. Wheatley, town clerk, Town Hall, Cardiff, in a sealed envelope, marked "Electric Light," by 14th inst.

Belfast.—The Town Council have approved of the minutes of the Electric Lighting Committee, which contained the following: "Your committee have to report that satisfactory progress has been made with the works for electric lighting since last meeting. The mains in the streets have been laid, the central-station building is approaching completion, the batteries and three of the engines have been delivered, and the overhead crane has been placed in position, and been tested by your engineer. Your committee have also to report that they have received applications for current for 2,360 8-c.p. lamps, which will about utilise the fourth of the generating power of the plant, and they anticipate a much greater demand." Approval has also been given to the appointment of Mr. Frederick Wilson as resident electrical engineer.

Aberdeen.—To meet the increasing demand for the electric light in Aberdeen, the Town Council have adopted the recommendation of the Gas and Electric Lighting Committee to double the present capacity of the electric lighting plant, as suggested by Prof. Kennedy. The total cost of the extension to plant and mains is estimated at £4,350. This, added to the amount already expended or contracted for, brings up the total capital cost of the electric lighting scheme to about £29,000. The distributing mains will be extended along both sides of Union-street, from their present termination at Bon-Accord-street to Holburn-street, at an expense of £950, making the total outlay for the present extensions £5,300. Prof. Kennedy reports that the demand for lighting has increased far more rapidly than he expected, and already nearly 7,000 lamps are connected to the mains, although the station has only been at work for six months.

Duplex Cables.—On Saturday last, in the Court of Appeal, before the Master of the Rolls and Lords Justices Lopes and Rigby, there was heard the case of Muirhead and others *v.* the Commercial Cable Company. This was an action to recover royalties involving about £45,000. The plaintiffs—John and Alexander Muirhead and Herbert Arnand Taylor—were patentees and proprietors of certain patents for a system of duplexing cables, known as Muirhead's duplex system, by means of which messages can be sent both ways simultaneously through a single cable. The defendants pleaded that the plaintiffs' patents had run out. The case was tried before Mr. Justice Kennedy without a jury, when he found for the plaintiffs for £3,000 odd. The defendants appealed. Sir R. Webster, Q.C., Mr. Moulton, Q.C., and Mr. A. J. Waller appeared for the appellants; and Mr. Finlay, Q.C., Mr. Bousfield, and Mr. E. H. Pollard, for the plaintiffs. At the conclusion of the arguments, which lasted for four days, the Court reserved judgment.

Dalton.—The minutes of the Highways and Lighting Committee of the Local Board presented at the last meeting of the Board bore that the clerk reported having, with Mr. Wardley, attended the conference of district local authorities at Ulverston on the 4th ult., when, as it appeared, notice by the electric company of intention to apply to the Board of Trade for an order to supply electricity been served on all the authorities represented, except that of the Dalton Local Board, and that the matter did not therefore materially affect the Board's district, they took no part in the resolutions adopted at the conference Mr. Wardley, in moving the adoption of the report, said there was not much in the report calling for comment, with the exception of the meeting on the electric lighting which was held at Ulverston. As instructed by the Board he attended, and when they had been in the meeting for a while, they found out that the electric lighting matter did not apply to Dalton at all, and so they retired from the meeting.

Reading.—The Town Council have approved of a report of the Highways and Lighting Committee in which it was stated that a sub-committee had conferred with Mr. McMullen, the electrical adviser of the Council, and were enabled to submit to him a section of the main which is being laid by the Reading Electric Supply Company, Limited, for the supply of electricity in this borough under the provisional order of the company, and they inspected with him the manner in which the mains were being laid, and the sub-committee had the satisfaction of stating that Mr. McMullen advised them that the main corresponded with the description in the rules and regulations prescribed by the Board of Trade relative to this borough, and that the main itself and the manner in which it was being laid were such as to ensure perfect safety to the public It appeared that the mains now being laid were low-pressure mains, and the sub-committee had requested the acting borough surveyor to obtain sections of the high-pressure mains proposed to be laid by the company, and when such sections were obtained the sub-committee would, if necessary, advise further with Mr. McMullen.

Norfolk.—Houghton Hall, the historical seat of the Walpole family, and one of Inigo Jones's finest works, has recently been furnished with a complete installation of electric light for the present occupier, Viscount Grey de Wilton, by the Planet Electrical Engineering Company, of Victoria-street, Westminster, and 67, Piccadilly. Over 500 lamps of 16 c.p. are used for the hall, which has a frontage of some 400ft., and for the stables, which are about 100 yards distant, where, in addition, a powerful arc lamp is used to light the yard. An outstanding portion of the mansion formerly used as a brewhouse has been altered to contain two complete sets of generating plant, consisting of two 16-h.p. oil-engines, two shunt-wound dynamos with heavy flywheels, and two sets of accumulators of large capacity. Each set of plant is capable of independently supplying the greater portion of the lighting, so that in case of a stoppage of one set of plant for repairs the second set will still continue in work, and the chances of a total failure of the lighting are almost nil, the accumulators alone being of a sufficient size to keep the light going for a considerable period. The whole of the work, including the designing of special fittings and shades and the adapting of the valuable chandeliers and other existing fittings, was carried out by the above company, under the supervision of their engineer, Mr. A. L. Shepard, and was successfully completed under contract within 10 weeks from the commencement.

Carlisle.—The Gas Committee of the Carlisle Town Council are now taking steps to obtain a provisional order to supply electric light in the city. The following resolutions have been passed: "That the site for the proposed electric lighting installation be Brockbank's yard or Boustead's grassing, and that the permissive area be the same as in the Carlisle Electric Lighting Order, 1883, and that the compulsory area be English-street, Market-place, Castle-street, Court square, Victoria-viaduct, Devonshire-street, Bank-street, and that part of Lowther-street from Bank-street to Devonshire-street; and that the engineer be instructed to undertake the engineering part of the application for the above order, with authority to engage the services of such consulting engineer as he may deem advisable in the event of its being necessary to do so." In the order of 1883 the area defined was as follows: "Within so much of the city of Carlisle as lies within the following boundary: Caldew Bridge, Annetwick-street, Finkle-street, West Tower-street, Scotch-street, the Market-place, a line thence to Lowther-street, at the junction of Victoria-place, Lowther-street, the Crescent, Botchergate, Crown-street, Currock-street, James-street, the Victoria-viaduct, to the River Caldew, and thence along the northern bank of the River Caldew to Caldew Bridge, the houses on both sides of such streets being included within the area." The compulsory area in the order of 1883 was English-street, Market-place, Court-square, and Victoria-viaduct (between James-street and English-street).

Snyers's Elastic Clutch.—In our last issue we referred, in an article on "Gas-Driven Alternators," to the use of Snyers's clutches used at Calais for coupling together alternators and gas-engines in the central station in that town. We now learn that the sole

Digitized by Google

licensees and makers of this coupling are Messrs. Cowlishaw, Walker, and Co., Limited, engineers, Etruria, Stoke-on-Trent, who supplied two clutches of this type to the Worcester water-power and electric light station, which was illustrated and described in this journal a few weeks ago Among the advantages claimed for the Snyers clutch may be mentioned: (1) total absence of shock, whether in running or starting the machine; (2) ability to start or stop the machinery at a very high speed without slowing down the engines—as an instance of this, the two clutches of 250 h p. each, running at 200 revolutions per minute, which transmit power to the dynamos which light Messrs. Cockerill's (Seraing) works, are started with the engine at full speed, the clutches slipping for about five seconds, when they bring the large dynamos up to full speed; (3) less wear and tear on the machinery and belting, owing to all sudden shocks and strains being taken up by the steel brushes; (4) wear and tear almost nil, the only wear being whilst the parts are being engaged; (5) immunity from breakdown, owing to the elasticity of driving, and to the clutches being made only slightly in excess of the power specified, which allows of the clutch slipping if any additional strain is thrown upon it, acting in the same way as the safety-valve of a steam-boiler. The makers state that Snyers clutches to the extent of transmitting upwards of 50 000 h.p. are now working successfully, and are being used for the transmission of power, shaft coupling, driving dynamos, hoists, pumps, steam and electric cranes, saw-mills, etc.

PROVISIONAL PATENTS, 1894.

OCTOBER 29.

20693. **An improved acoustic device for telephones.** Albertus Maseland, 45, Southampton-buildings, Chancery-lane, London.

20703. **Improved telephonic switch and indicator.** George Lee Anders, 33, Peak Hill-gardens, Sydenham, London.

20716. **Improvements in and connected with portable electric lighting circuits and illuminating devices.** Percy Tilt Letchford, 22, Southampton-buildings, Chancery-lane, London.

OCTOBER 30.

20746. **An electrical prepayment gas-meter.** Frank Villiers-Stead, 44, Gutter-lane, Cheapside, London.

20783. **An improved telephone transformer.** Joseph William Ray, 10, Waterloo-place, North Shields.

20784. **Improvements in electric incandescent or arc lamps.** Hector Joseph Bonaventure Thiroux, 70, Palace-chambers, Westminster.

20807. **Improvements in telegraph transmitters.** Herbert Arnaud Taylor, 24, Southampton-buildings, Chancery-lane, London.

OCTOBER 31.

20827. **An improved telephone switchboard jack.** James Taylor, Helsby, Warrington.

20842. **Improvements in propelling road and railway vehicles by electricity.** Thomas Machin, 36, Temple-street, Birmingham.

20843. **Improvements relating to road or railway vehicles propelled by electricity.** Thomas Machin, 36, Temple-street, Birmingham.

20886. **Improvements in and relating to telegraphic relays.** Archibald David MacDonald, 191, Fleet-street, London. (Complete specification.)

NOVEMBER 1.

20917. **Improvements in or connected with incandescent electric lamps.** Herbert Hampton Hall, 15, Water-street, Liverpool.

20959. **New or improved regulating switch for electric lamps and other electric apparatus.** Albert Edward Williamson, Edward Lionel Joseph, and the Electric Light Regulating Syndicate, Limited, 115, Cannon-street, London.

NOVEMBER 2.

21043. **Improvements in the method of damping marine and other mirror galvanometers making them absolutely dead beat.** Thomas Clark and Thomas Edwin Weatherall, 66, Jerningham-road, Hatcham, London.

21045. **Improvements in alternate-current dynamo-electric machines.** Maurice Hutin and Maurice Leblanc, 28, Southampton-buildings, Chancery-lane, London.

21080. **Improvements in secondary batteries.** Charles Laugier, 4, South-street, Finsbury, London.

NOVEMBER 3.

21098. **A novel or improved process and means for obtaining electrical energy from fuel gases.** Wilhelm Borchers, 57, Barton-arcade, Manchester. (Complete specification.)

21104. **Improvements in grooved mouldings or casements for the concealment of electric wires and the like, in combination with picture rail and such like mouldings.** George Grant, 103, Wickersley-road, Lavender-hill, Battersea, London.

21140. **Apparatus for controlling electrical illumination.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Messrs. Siemens and Halske, Germany.)

21141. **Improved means for controlling the induced currents in short-circuited windings of the armatures of electromotors worked with rotary-phase alternating currents.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Messrs. Siemens and Halske, Germany.)

21142. **Improvements in apparatus for starting and reversing the motion of electromotors.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Messrs. Siemens and Halske, Germany.)

SPECIFICATIONS PUBLISHED.

1893.

3572. **Printing telegraph receiving instruments.** Wright. (Second edition.)

19283. **Electric heater.** De Segundo and Derham.

20793. **Recording instruments for electric telegraphs.** Muirhead.

22817. **Electric meters** Aron.

23083. **Recording electric currents.** Aron.

23221. **Incandescent electric lamps.** Lake. (Hussey and another.)

23366. **Phonographs.** Lioret.

24285. **Electroliers, brackets for electric lamps, etc.** Edmunds.

24790. **Dynamo-electric machines.** Crompton.

1894.

8654. **Electric light chandeliers.** Grenville and Terry.

13749. **Electric signalling apparatus.** Allison. (Standard Electric Signal Company.)

13750. **Electric signalling apparatus.** Allison. (Standard Electric Signal Company.)

13751. **Electric signalling apparatus.** Allison. (Standard Electric Signal Company.)

15082. **Magneto-electric machines for cycles, etc.** Tillman and Lexow.

16695. **Electric lighting and extinguishing devices for gas lamps.** Bruck.

16825. **Electromagnetic car brake and traction device.** Murray and Allen.

17284. **Transforming and distributing electric currents.** McElroy.

NOTES.

Telephony in Hungary.—The Oedenburg town telephone system will shortly be connected with the interurban system.

Electric Traction in France.—A line of electric tramways is projected by M. Claret between Néris and Montluçon, Allier.

News.—The *Sun* has just made the astonishing discovery that on the Nelson column nightly advertisements are worked by means of a small limelight!

Electric Traction at the Cape.—The Town Council of Cape Town have approved of a scheme for providing electric tramways for the town.

Electric Lighting in France.—The Vire electric lighting company have announced that until their works are completely finished they cannot supply current during the day, but only at night.

Electrical Trades Union.—Owing to the office of general secretary being vacant, all communications are to be addressed to Mr. R. Steadman, general secretary *pro tem.*, Club and Institute Buildings, Clerkenwell-road, E.C.

Institution of Junior Engineers.—The inaugural meeting of the fourteenth session of this institution will be held to-night (Friday), at the Westminster Palace Hotel, when the presidential address will be delivered by Mr. Alexander Siemens.

Electric Traction in Russia.—Mr. F. A. Gerle, a Moscow contractor, has offered to construct an electric tramway from the fair-ground at Nishni-Novgorod to the Moscow-Nishegorod railway station at his own expense without any Government subsidy.

Lighting Circuits and Electro-Therapeutics.—In *L'Electricien* of the 3rd inst., M. E. Meylan contributes an illustrated article dealing with the system devised by MM. Gautier and Larat for utilising current from town lighting circuits in connection with electro-therapeutics.

Trafalgar-square Search-light.—At the instance of the St. Martin's Vestry, a communication has been forwarded to her Majesty's Office of Works protesting against the desecration of public monuments and buildings in Trafalgar-square by means of search-light advertisements.

Telegraphy in India.—A proposal made by the Deputy Commissioner of Dera Ismail Khan for doubling the telegraph wire at once from Dera to Tonk, and also to arrange for a full field telegraph to accompany the Afghan-Waziristan delimitation party, will be adopted by the Government of India.

Northern Society of Electrical Engineers.—A ballot for new members of this society took place on Monday, when the following were elected: Mr. J. D. Bailie, of Leeds; Mr. A. H. Gibbings, of Hull; Mr. W. J. Hide, of Liverpool; Mr. C. F. McInnes, of Leicester; Mr. W. D. Reid, of Nottingham; and Mr. Joseph Tinker, of Newton, near Hyde.

Institution of Engineers and Shipbuilders.—The second general meeting of the present session of the North-East Coast Institution of Engineers and Shipbuilders will be held in the Athenæum, Church-street, West Hartlepool, on Saturday, the 17th inst., at 6 p.m. A paper on "A Brief Outline of the Theory of the Rolling of Ships," by Mr. Andrew Young, will be read and discussed.

Electric Transmission in Austria-Hungary.—Messrs. B. Egger and Co. have received an order to establish an electric power transmission plant at the gold-mines of Messrs. Stantien and Becker at Nagy Almas. There will be six electric motors of a total of about 150 h.p., the pressure being 500 volts. The motors will be used for the working of hauling machines, pumps, and ventilators.

Cost of Lighting Calcutta.—There were 5,952 gas lamps and 1,647 oil lamps in Calcutta at the close of 1893-94. The actual cost of lighting the gas and oil lamps was Rs. 3,58,966-8-9 against Rs. 3,44,326 in the previous year, showing an increase of Rs. 14,640-8-3 on account of the increased number. This gives an average of Rs. 60-5-0 per lamp per annum. Electric lighters, says the *Indian Engineer*, will please note.

Joint-Stock Companies.—The Board of Trade have appointed a committee to enquire what amendments are necessary in the Acts relating to joint-stock companies incorporated with limited liability, especially with a view to the better prevention of fraud in relation to the formation and management of companies, and to consider and report upon the clauses of a draft Bill which will be laid before them for that purpose.

Madras Electric Tramway.—We referred to this concern last week. The *Indian Engineer* now says: "The Madras Electric Tramways Company does not seem to be making progress. According to the terms of the concession, and making due allowance for the six months' extension granted to the company by Government last year, sections No. 1 and 2 of the tramways should be substantially complete and open for traffic on this date. But they are not."

Light Railways.—The President of the Board of Trade has appointed Thursday, December 6, as the date for the assembling of the proposed conference on the subject of light railways. The conference will meet at 8, Richmond-terrace, Whitehall, S.W., at eleven in the morning, and will sit till half-past one in the afternoon. It will then adjourn till half-past two, and sit till half-past four. The question of adjournment will be considered at a quarter-past four.

Society of Arts.—Among the papers to be delivered after Christmas are: "The Use of Electricity for Cooking and Heating," by Mr. R. E. Crompton; and "Electric Lighting of Ecclesiastical Buildings," by Major-General C. E. Webber, C.B. Prof. Silvanus P. Thompson will also deliver three Cantor lectures on "The Arc Light." On Wednesday next, at 8 p.m., the opening address of the one hundred and forty-first session will be given by Major-General Sir John Donnelly, K.C.B., chairman of the council.

Direct Calculator.—We have received from Messrs. Crosby Lockwood and Co. a copy of the "Direct Calculator (Es)," compiled by Mr. M. B. Cotsworth, Holgate, York, who has previously issued other calculating tables. The present book is simple and well arranged, and shows at a glance the values of all weights from 1lb. to 1,000 tons at all rates to £100 a ton, by penny gradations from a penny to 40s. per ton, and thence by £2 gradations, so that only one addition is required to cover every penny rate to £100 per ton.

Symbols for Physical Quantities.—Our contemporary the *Electrical World*, of New York, has issued a reprint of the symbols for physical quantities and abbreviations for units as recommended by the Committee on Notation of the Chamber of Delegates of the International Electrical Congress of 1893. To the card containing these symbols, which has been corrected by M. E. Hospitalier, have been added in italics the names of the practical mag-

Digitized by Google

netic units provisionally adopted by the American Institute of Electrical Engineers.

Royal Meteorological Society.—An ordinary meeting of this society will be held at 25, Great George-street, Westminster, on Wednesday next, the 21st inst., at 7.30 p.m. Papers on the following subjects will be read: "Methods of Determining the Influence of Springs on the Temperature of a River, as illustrated by the Thames and its Tributaries," by Mr. H. B. Guppy, M.B.; "Some Effects of the Gale in the Highlands of Scotland on November 17th and 18th, 1893," by Mr. Eric S. Bruce, M.A., F.R.Met.Soc.; and "History of a Waterspout," by Mr. Alfred B. Wollaston.

Institution of Electrical Engineers.—A meeting of this Institution will be held at 25, Great George-street, S.W., on Thursday next, the 22nd inst., commencing at 8 p.m. A paper on "Electrical Steep Grade Traction in Europe," by Mr. Charles S. du Riche Preller, M.A., Ph.D., member, will be read, and discussion will take place on the papers entitled "Notes on Electric Tramways in the United States, Canada," by Mr. H. D. Wilkinson, member; and on "Electric Traction, with Special Reference to the Installation of Elevated Conductors," by Messrs. R. W. Blackwell, foreign member, and Philip Dawson, associate.

Bordeaux Exhibition.—A meeting of members of the London Chamber of Commerce and others has been held, at which the following motion was adopted: "That the London Chamber of Commerce should be requested to form a committee (with power to add to its number) for the purpose of ascertaining whether adequate British representation, either general or special, can be secured, and, in such case, to lend its advice and aid for the purpose, subject to its being reasonably satisfied with the conditions upon which the exhibition is to be held." Information may be obtained at the offices of the Chamber, Botolph House, Eastcheap.

Mahatmas and Electricity.—Mr. Herbert Burrows, having been interviewed on the subject of whether the Mahatmas are humbugs, has said: "I see Mrs. Besant recently stated in Australia that she had seen a Mahatma. This probably meant she had seen what is called his astral body, which again means simply that she has so trained herself as to be receptive of the vibrations of which this astral matter is composed. Here we have only a development of Tesla's wonderful experiments with regard to electricity and its rapidity of vibration. There is no miracle, nothing supernatural; nothing miraculous or supernatural is claimed." The analogy is not very evident.

Utilisation of Water Power.—An interesting installation of the utilisation of water power is just being completed at the works of M. Andrieu under the superintendence of M. Juppont, of Toulouse. The station, which is to be operated by the water power of the Lot, is equipped with two Fontaine turbines giving 200 h.p. under a head of 17ft. The total power available is 600 h.p., but only the two motors in question will be worked for the present for the operation of the Capdenac Works, and for the lighting of the principal streets in that town and for the supply of light to private consumers. As the generating station, which contains three Thomson-Houston dynamos (of which one is reserve), is situated 700 metres from the district to be supplied, the three-wire system of distribution at 240 volts has been adopted. After providing for the above requirements, the surplus power will be used in connection with neighbouring industries.

Lecture.—Sir H. Roscoe, M.P., in distributing prizes at the Sheffield Technical Schools last week, remarked that hitherto we had been raising only starving clerks, and had ignored the means by which to make the intelligent and able artisan. England had now, however, learned from France and Germany the importance of technical education, and the House of Commons had awakened to the national danger created by our neglect of that duty. On the whole, he thought the money granted to local authorities for technical education was being well spent. The county councils were learning their business, and he was surprised that they were learning it so quickly. Upon the successful solution of the problem of technical education depended not only our commercial supremacy, but also our national existence. What we now needed in our schools was a continuous system of object lessons from the kindergarten until special scientific subjects were begun.

Accident in Cannon-street.—The daily papers this week announced that on Saturday afternoon a horse was killed by an electric shock in Cannon-street at the corner of Walbrook, that two or three persons received slight shocks, and that three explosions occurred in the locality about the same time. As a public enquiry into the accident will be held by the Board of Trade on Monday next, the 19th inst., commencing at 11 a.m., in No. 174 hall, Winchester House, Old Broad-street, E.C., the City of London Electric Lighting Company, Limited, desire us to state that pending such enquiry they do not consider it advisable to make any statement on the matter. In the meantime, the British Insulated Wire Company, of Prescot, ask us to mention that their cables are in no way responsible for this accident. The daily papers also stated erroneously that a similar event occurred some time ago either at Brighton or at Eastbourne, but this is now being corrected by different correspondents to Bournemouth.

Electric Lighting in Germany.—The buildings of the Reichstag, Berlin, have been lighted by electricity. There are 62 arc lamps, of which 16, of 15,000 c.p., are placed in the large hall. There are also about 5,000 incandescent lamps. The question is being considered whether the subject of the electric lighting of Brunswick could not be settled at the same time as the introduction of electric traction on the tramways. The Municipality of Bayreuth have decided not to establish a central electric lighting station owing to other heavy liabilities incurred for next year. At Landshut applications have been received for about 1,150 lamps. This is more than was anticipated. The premises of the Kleinhammer Brewery Company, Dantsic, are to be lighted electrically. Mr. W. Reisser, of Stuttgart, has received authority from the Minister of the Interior to establish a central station at Horb. A central electric light station is to be opened this month at Reisslingen. There has been a good demand from private consumers, and the streets are to be lighted electrically. The Trade School, Leipsic, is to be lighted by electricity.

Catalogue of Electrical Plant.—It has now become a recognised course to pursue, in issuing new catalogues, to embody in them useful information to elucidate the questions which arise in the minds of the public when considering the subject of laying down private plant for the supply of electric light. This policy has been adopted in the new catalogue brought out by Messrs. Henry F. Joel and Co., of 31, Wilson-street, Finsbury, E.C., who first discuss the suitability of steam, gas, and oil engines for particular cases, and then give plans showing the positions of lamps in West-end and other houses. This is followed by information concerning the fixing and operation of dynamos, motors, arc lamps, and accumulators, and which is of value to residents in the provinces and the colonies. Illustrations and details are next given of vertical and horizontal steam-engines, boilers, gas and oil engines, and turbines. Joel's slow-speed dynamos and alternating-current motors,

Digitized by Google

the latter with a guaranteed efficiency of 40 per cent. for small ¼-h.p. motors, occupy a prominent position, together with the Joel-Pilsen arc lamp and photographic arc lamps. The list concludes with references to storage batteries, switchboards and switches, voltmeters, ammeters, incandescent lamps and accessories, and electric cooking and heating appliances.

Electric Transmission in Agriculture.—Messrs. Ganz and Co. have this summer carried out an interesting electric installation on the lands of Count Ugarte-Lowaletti at Jaispitz, in Moravia, which is used purely for agricultural purposes. On the estate a steam sawmill has been erected, and here 30 h.p. was reserved for the purpose of the electrical transmission plant. From this generating station two circuits are carried in different directions. One of these leads to a mill and dairy, with a branch to a neighbouring barn; while the second circuit leads to another barn. In the secondary stations there are two 12-h.p. electric motors in the two barns, and a 10-h.p. motor in the dairy. At the primary station there is a continuous-current dynamo of 35 amperes and 620 volts regulated by a Blathy automatic pressure governor. At the dairy two centrifugal machines, a pump, and other machinery are driven. Near here there is a mill which formerly could only be worked for a short time in the year owing to insufficiency of water power. This mill has now been so arranged that it can be driven by the motor in the dairy. In the two barns the motors are used for driving thrashing-machines. The motors are portable, being mounted on carriages, and can be taken out into the open field, connection being made by branch conductors with the main overhead cables.

Electrocution in America.—Things are coming to a pretty pass if the following blood-and-thundery Dalziel's cablegram is to be credited. It runs: "The question of the possible survival of criminals who have been executed by means of electricity has been frequently discussed in America, and as opinions are greatly divided on the subject, the Hon. Roswell P. Flower, Governor of the State of New York, announces that he will permit an experiment to be made to settle this point. A man named Wilson is now under sentence of death and will be electrocuted next month. The doctors who attend the execution in order to certify to the cause of death and make the *post-mortem* examination are, in accordance with the governor's decision, to be allowed to attempt to resuscitate him, and if they succeed Wilson will be pardoned. In the first executions by means of electricity as prescribed under the change of law in New York State, about four years ago, the public was greatly shocked by published statements that the criminals breathed and even groaned after the first shock had been passed through their frames. Later, with improvements in the apparatus, these phenomena were not observed, but in order to ensure that life should be absolutely extinct, the current has been applied for a certain number of seconds, then shut off and turned on again, although the first application was really considered sufficient."

Electro-Harmonic Society.—The first ladies' night of this society for this season will take place on Friday, the 30th inst., at the St. James's Hall Restaurant (Banquet-room), Regent-street, W., commencing at eight o'clock. The following is the programme—Part I.: trio, "A Wish" (M. B. Foster), Miss Mary Harris, Miss Vena Galbraith, and Mr. Reginald Groome; berceuse, "Angels Guard Thee" (B. Godard), Mr. Reginald Groome; aria, "Nobil Signor" ("Les Hugenots") (Meyerbeer), Miss Mary Harris; recitation, "The Road to Heaven" (with music) (G. R. Sims), Miss Charlotte Boucher; whistling solo, "Should He Upbraid" (Bishop), Mr. Charles Capper; song, "The Magic of Thy Voice" (Meyer Helmund), Miss Vena Galbraith; original musical sketch, "Seaside Recollections" (R. Henry), Mr. Roland Henry. Part II.: pianoforte solo, "Andante and Rondo Capriccio" (Mendelssohn), Mr. Alfred E. Izard; songs (*a*) "If my Verses had the Wings," (*b*) "O, my Love's like the Red Red Rose" (H. Lohr), Mr. Reginald Groome; song, "Because I Love Thee" (E. Ford), Miss Mary Harris; recitations, (*a*) "The Duett" (with music), (*b*) "Answered" (Ella Wheeler), Miss Charlotte Boucher; whistling solo, "Chaconne" (Durand), Mr. Charles Capper; song, "When We Meet" (Hope Temple), Miss Vena Galbraith; and original humorous selection (R. Henry), Mr. Roland Henry. The musical directors are Messrs. T. E. Gatehouse and Alfred E. Izard.

The Million Battery.—A bronze medal has been awarded by the jury of the Lyons Exhibition to the Million battery, which is a modification of the bichromate battery. According to the *Bulletin International de l'Electricité*, the battery consists of a porous annular vase containing a solution of sulphuric acid, in which is placed an amalgamated zinc plate forming the negative pole. Around this vase are arranged carbon rods connected together at the top and bottom by means of two lead crowns, to which they are soldered, and constituting a large depolarising surface and the positive pole. The central part of the porous vase is occupied by a small crown of carbon rods connected to the external crown, and allowing of the zinc being worked on both sides. The whole is contained in an external vessel of glass, enamelled iron, or lead according to circumstances, which serves as the receptacle for a depolarising solution of bichromate of soda in acidulated water. A cell of this kind is said to have a capacity of from 160 to 180 ampere-hours, the discharge being varied at will. Moreover, it is claimed by the separation of the liquids that polarisation is overcome. The E.M.F. of the cell is given as follows:

2·1	volts on open circuit.			
1·9	„	with a discharge of	5	amperes.
1·8	„	„	10	„
1·7	„	„	15	„
1·6	„	„	20	„
1·5	„	„	25	„

It is mentioned that this type of battery has been employed for a variety of purposes.

Traction on Canals.—A communication referring to electric and mechanical propulsion on canals was presented recently by M. Maurice Lévy to the French Academy of Sciences. The author, in pointing out how mechanical engineering had progressed and been applied in all branches of industry, stated that it was strange in the case of canals that we had adhered to the primitive method of haulage by horses, a system that had been in use for over three centuries. No doubt its continued employment was due to the fact that this method was simple and economical, and because the traffic handled was small. This system, however, no longer met the requirements of modern canals. With a view to solve the problem, M. Lévy has investigated the matter for four years, and he believes he has discovered a practical solution. The method devised by him consists in haulage by means of a teledynamic cable, and which system has been successfully experimented with on a three-mile length of the Saint-Maur and Saint-Maurice canals. This idea has been tested in Germany on the canal from the Oder to the Spree, and if the results were not as satisfactory as they should have been, the author states that this is attributable to an incorrect reproduction of his arrangement. He mentioned that the experiments with the system made in France were so conclusive that the

Digitized by Google

method has been adopted on a large scale on the canal from the Aisne to the Marne, where it will be in regular operation by the end of the present year.

The Pacific Cable.—The tenders for the construction of the proposed Pacific cable were opened at Ottawa on the 9th inst. They are six in number, and all have been sent from England. The figures have not been made public, but it is said that all are lower than the estimate furnished by the engineers. A *Times* correspondent, cabling from Ottawa on the 9th inst., says: "Mr. Mackenzie Bowell and Mr. Fleming to-day opened tenders for the proposed Pacific cable. Six were received, covering each of the eight routes proposed. In all cases they were below Mr. Fleming's estimates, and were much more favourable than was thought likely by some of the delegates to the recent Intercolonial Conference. Before the details are announced Mr. Mackenzie Bowell will communicate them to the different colonial Governments." A cable message, received in Ottawa on Tuesday, according to the same correspondent, stated that Lord Ripon has in contemplation the calling of another inter-colonial conference. Mr. Mackenzie Bowell, in the course of a speech on the same day, said that he saw no necessity for the immediate gathering of another conference, when the Governments interested were already in possession of all the necessary facts respecting the proposed Pacific cable. A conference, he thought, might be necessary to make final arrangements. The delegates of the Imperial and colonial Governments would then require to be in a position to pledge their respective Governments on the question of liability. Mr. Mercer left for England on Tuesday. Before his departure he had an interview with Mr. Mackenzie Bowell on Hawaiian and cable questions, and expressed much satisfaction at the fact that the cable can reach land without touching the Hawaiian group.

Electric Traction in Germany.—Two new electric tramways are about to be opened in Hamburg—namely, the "Blue Ring"—from Rathausmarkt *viâ* Rothenbaum-Chaussée to Eppendorferbaum, and half of the Alster line from Rathausmarkt to Eppendorf (Friedenseiche). The line from Zeughausmarkt to St. Pauli, etc., will also be shortly completed. At present the central electric supply station has not sufficient machinery in place to supply power for this additional demand. About February a line between Barmbeck and Ohlsdorf (Hamburg) will be opened. Negotiations are on foot in Halle between the Allgemeine Elektricitäts-Gesellschaft and the Halle Tramway Company for the purchase by the latter of the electric tramway belonging to the former, and the extension of electric traction to the lines of the horse tramway company by the electrical company. It is proposed to build an electric tramway between Wiesbaden and Walkmühle. It is expected that the working of the electric tramway between Heinersdorf, Pankow, and Gesundbrunnen (Berlin) will be commenced before the New Year, at any rate on the stretch between the corner of the Badstrasse and Prinzenalle to the Breitenstrasse in Pankow. There is a good deal of work being done in connection with electric traction at Barmen-Elberfeld. The Municipality of Barmen have commissioned Messrs. Siemens and Halske to construct an electric tramway to Wicklinghausen, while the Elberfeld authorities have instructed the Berliner Elektricitäts-Gesellschaft Union to build a new electric line running from north to south. At the same time, some horse tramway lines, owned by a Belgian company, are to be turned into electric lines. Messrs. Siemens and Halske have received a concession for the construction of an electric tramway between Schalke, Gilsenkirchen, and Wattenscheid-Bochum. An electric tramway is to be built at Lupree by the Allgemeine Elektricitäts-Gesellschaft.

Institution of Civil Engineers.—The seventy-seventh session of the institution was opened on Tuesday evening, when a short address by the president (Sir Robert Rawlinson, K.C.B.) was delivered to the members. Alluding to the works in progress for the construction of the new building, Sir Robert Rawlinson recapitulated briefly the several stages of development as regards accommodation through which the institution had passed since its foundation in the year 1818. Referring to the library, he reminded the members that they were the possessors of a most valuable collection of books treating of or bearing upon every branch of civil engineering. Upwards of 50,000 volumes were now upon the shelves, and it was a matter for congratulation that such arrangements had been made as would permit the members to have access to these works during the building operations. Nor would the transition from the old to the new premises be suffered to interfere with the work of publication carried on by the institution. Already the series of *Minutes of Proceedings* had reached to 118 volumes. Of each one of the four volumes annually issued 7,000 copies were printed and distributed, and those important records of fact and experience might be consulted in every civilised country in the world. The president then sketched in outline the rise and development of civil engineering in Great Britain. On the motion of Mr. James Abernethy, past president, seconded by Sir Frederick Bramwell, Bart., past president, a hearty vote of thanks was accorded to the president for his address, which he was requested to allow to appear in the *Minutes of Proceedings*. The president then presented the medals and premiums awarded to the authors of original communications dealt with during the preceding session. A students' meeting will be held this evening, when a paper will be read on "The Economics of Direct-Current Central Stations" by Mr. John F. Snell. Prof. A. B. W. Kennedy will occupy the chair.

Rapid Transit in Europe.—An investigation of the European systems of rapid transit has been made by Mr. Wm. Barclay Parsons, A.Mm.S.C.E., on behalf of the Rapid Transit Commission of New York City. Mr. Parsons, pursuant to a resolution of the commission, inspected the several railways in operation and under construction in London, Glasgow, Liverpool, and Paris. Pending the writing of such a report as the importance of the subject demands, he makes a preliminary statement giving the leading constructive features of the several foreign lines. After describing the lines in those cities, the writer says: "This report is, of course, but a description of the several railways which were inspected during the past summer, and it is not intended in any way to suggest or recommend any particular form of tunnel for use in New York. As the local conditions of no two cities are the same, it is impossible to select any one type, however successful it may be under its particular conditions, as the type to be produced elsewhere. In the study of the foreign systems, however, much information has been gathered, and many fruitful suggestions gained, which will hereafter be of value to your Board in the carrying out of your future work, although that work may differ from, and it is hoped be an improvement on, any of the above-described railways. The conclusions arrived at from such an investigation, both from the study of the actual works and from personal interviews with their designers, are: (1) that an underground railway operated by steam, even with the most approved system of mechanical ventilation, would be intolerable to the people of the city of New York; (2) that a railway with a steady, frequent service can be operated successfully and economically by electricity; (3) that an underground railway operated by

Digitized by Google

electricity has a comfortable atmosphere, and that it can be arranged so as to avoid great changes in temperature; (4) the advice and experience of foreign engineers lean toward keeping the rail level as close to the surface as possible, and that excavating from the surface is cheaper and safer than tunnelling; but (5) if conditions demand, a deep tunnel can be constructed, for which the circular form is best; (6) that an underground road can be so designed as to be attractive in appearance; (7) that the work can be carried on through a busy street without endangering the houses, and without seriously impeding travel."

The Perfect Incandescent Lamp.—A series of articles by M. A. Bainville dealing with the manufacture of incandescent lamps, is being published in *L'Electricien*. The author having passed through the various operations in the production of these lamps, commences in the pages of our contemporary of the 10th inst. to consider the perfect incandescent electric lamp. It is very evident, he observes, that the present types of lamps are far from reaching the ideal. In what way shall we go to attain better results, and what are the most imperfect points which it is most desirous to remedy? Some of the imperfections possessed by the incandescent lamp are inherent, belonging to the principle upon which its construction lies; others depend upon the manner in which this principle is applied. Dealing first with the latter, the author states that the filament is a bad transformer of electrical energy into luminous energy since existing lamps have barely an efficiency of 5 per cent., and by increasing their working temperature we cannot expect to obtain in luminous energy more than 10 per cent. of the electrical energy consumed. We may from now consider that the most progress realisable lies in increasing the efficiency of this transformation. The principal other defects of the filament are caused by the wear of the filament; they are due to the variation of the electrical resistance, and also to the variation of the nature of the surface of the filament, which has equally a considerable influence upon the value of the lighting power. The more or less transparency of the bulb, and especially the modifications it undergoes during the life of the lamp, are also comprised in the imperfections of manufacture. This transparency is, moreover, intimately connected with the quality of the filament, since the layer of carbon which produces this diminution in transparency of the bulb arises solely from the filament. M. Bainville contends that the perfect incandescent lamp can be defined as that in which the physical properties of the filament remain constant during the whole of its life; this duration is tolerably long, such, for instance, as that of existing lamps; the filament would be enclosed in a bulb of perfect transparency and constant during the life of the lamp; the vacuum in the bulb should be accomplished in such a manner as to be as near as possible an absolute vacuum, and it should be maintained in such a condition all the time the lamp is in operation. A lamp of this kind should, moreover, automatically terminate its life as soon as one of the conditions enumerated becomes unfulfilled. The question naturally arises, how can these requirements be met? Passing on to a consideration of this matter, with special reference to the composition of the filament, the author concludes that investigations into the improvements to be introduced in incandescent lamps should be devoted to a realisation of filaments formed of a single substance, and not of a mixture. This substance should possess the properties of infusibility at least equal to that of carbon, a higher specific resistance, large emissive power, and be very elastic. Apart from this solution, the author observes it might perhaps be possible to effect the transformation of electrical energy into luminous radiations in a more perfect way than by the method of incandescence. The luminous phenomena which accompany discharges in vacuum, and the illumination presented by rarefied air-tubes placed in the magnetic fields of high frequency, as, for instance, those of the Tesla kind, may be the point of departure of new and fruitful investigation.

Contiguous Gas and Electric Mains.—Before a general meeting, held last week in London, of the Southern District Association of Gas Engineers and Managers, a paper by Mr. S. W. Durkin, of Southampton, having the peculiar title of "How an Electric Current introduced Gas into an Electric Culvert," was read. The author first referred to the commencement of the operations of the Southampton Electric Light and Power Company, and to the protection afforded by the latter to the gas-mains laid in the same streets as the electric light conductors. Proceeding, he said: "The electric company have now been supplying current for several years from a low-tension plant, and it appears to be a very good example of central-station lighting. Up till October 16 last the two underground systems for supplying each kind of artificial light had gone on without molesting each other, or disturbing person or property. On the evening of October 15, however, there was, it seems, a leakage on one section of the electric mains. On the following morning the electric light inspector went into the High-street to localise it. After opening up one or two covers, the man detected gas, and soon after telephoned to the gasworks for our inspector to come to his assistance. The latter, on arriving on the scene of action, had the whole of the traps over the section opened up, and as they went down the street gas was scented more and more strongly, until they came very near to what proved to be the source of the mischief. I was sent for, and the question was what to do in the emergency to prevent any mishap and to stop the gas leakage. The gas-main was under the kerb, so that the service pipes were short in length. These latter I determined to strip and examine. Another precaution was to isolate the main; but, fortunately, this became unnecessary, as the second service we opened, and which passed under the floor of the culvert, revealed the cause of the mischief. The electric mains, as previously stated, are laid for the low-tension system, and are strained up to bridges placed at intervals across the culvert. These mains are formed of copper bars about 1in. by ¼in. in section. The gas service was supposed to be insulated by a stoneware tile, semi-circular in section, embedded in Portland cement rendering on each side, but the centre was above the culvert floor. This insulation might have continued had the copper main kept its original position, but from some cause it sagged (perhaps from a holdfast breaking) and rested on the insulating tile. Then the electric current, anxious to leave its copper-bound lodging, made a crater-shaped hole through the tile. The fused portion of the tile and the perforated service pipe are now before you. The opening is about 0·75in. in area, and of irregular form. The copper main was fused and fell asunder, dropping far enough away to prevent further short-circuiting. There was evidence of the gas having been lighted, there being a deposit of carbon found on the stone cover of the culvert. But for some reason the flame went out; the presumption is that it was for want of air to support combustion. It was very satisfactory that no explosion had occurred. At the same time this incident shows the culvert system to be one likely to lead to disaster when in close proximity to gas-mains in public thoroughfares. In this instance there were 360 yards of culvert charged with gas. The damage was soon made good by those concerned, and a new form of insulator inserted, which, I trust, will prove more reliable than its predecessor."

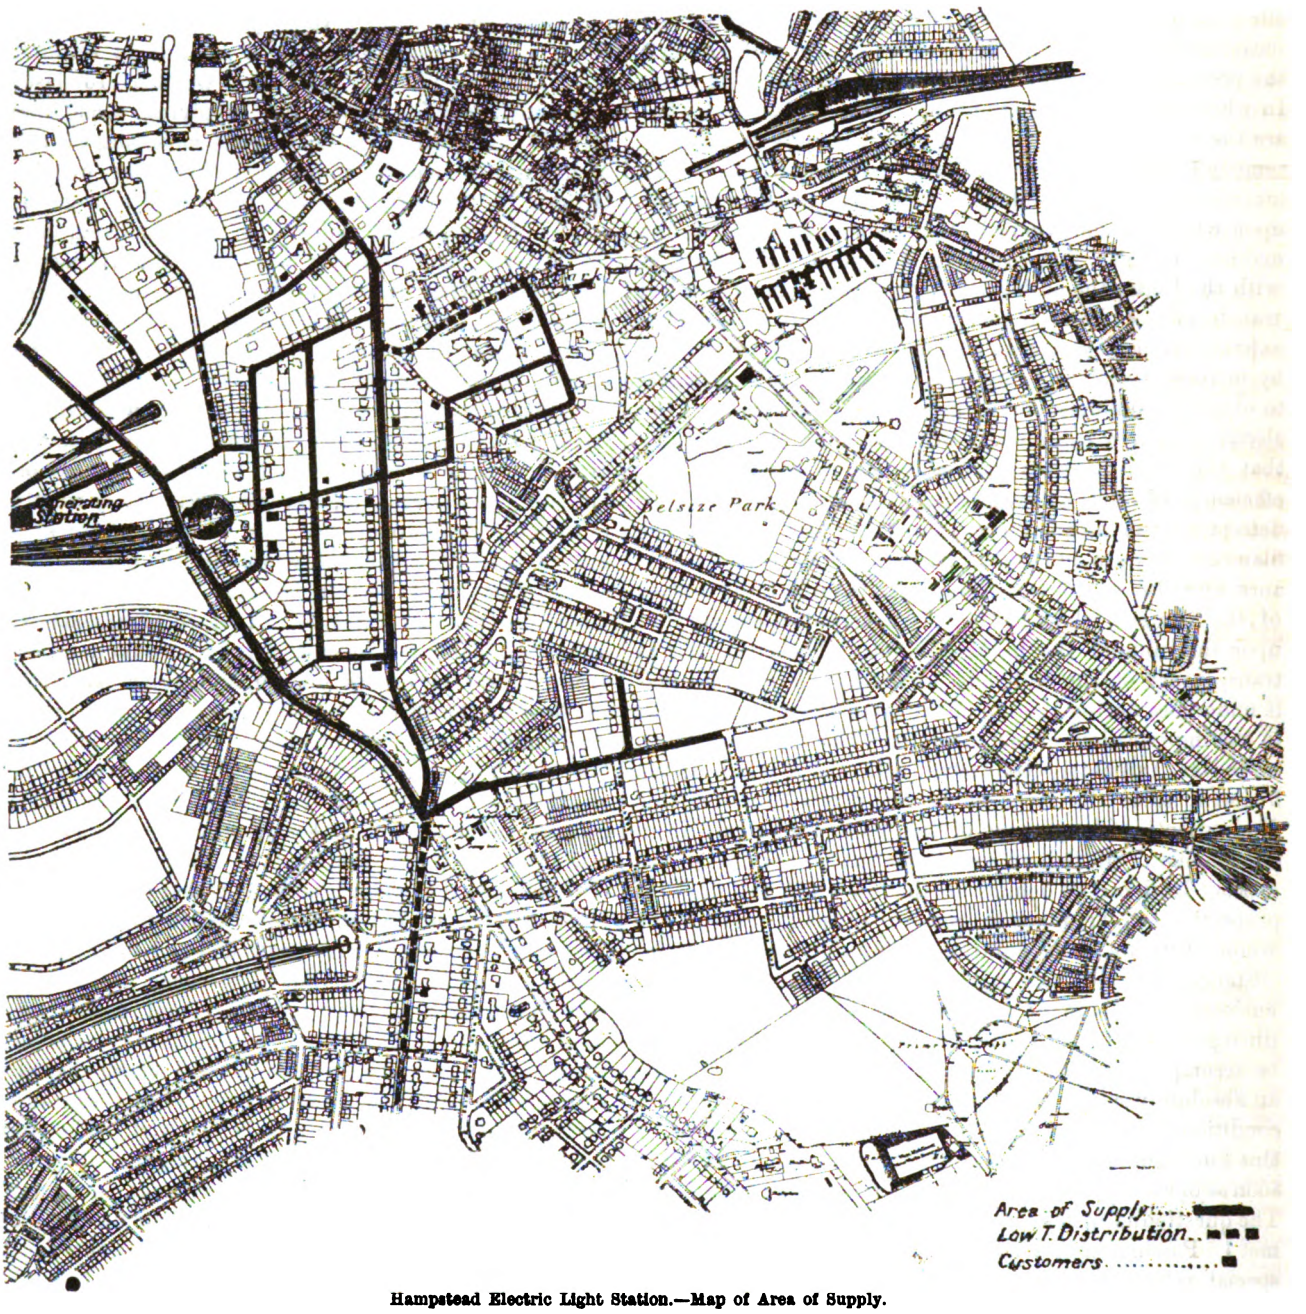
MUNICIPAL AND COUNTY ENGINEERS.

On Saturday, November 3, among other visits, the Association of Municipal and County Engineers went to the Hampstead central station to inspect the works and hear a paper on the station by Mr. W. H. Preece, C.B., F.R.S. The paper was descriptive of the station. Our readers must be pretty familiar with the arrangements of this station from our description of October 5 last. We are, however, now able to supplement that description with a few more illustrations and details.

Hampstead Central Station.

SUPPLEMENTAL DESCRIPTION.

The accompanying plan of the district will give an idea of the position of station and area wherein current is now being distributed or arranged for.



Hampstead Electric Light Station.—Map of Area of Supply.

The dynamos are direct driven by Willans engines, and, speaking of these engines, Mr. Preece said they had had with them considerable experience. They had upwards of 30 in different post offices, which were found to work with absolute perfection, and he had never known of any trouble with them. They gave immense satisfaction, were direct driving, and for compactness were far preferable to any system of rope or belt driving. These engines were coupled direct to Siemens alternators. The combination is illustrated in Figs. 1 and 2.

The switchboard, Fig. 3, was well werth attention. They would observe from the elevation of the switchboard (the connections on which are shown diagrammatically) that three arc light panels were arranged on the extreme left. The middle one was for ammeter and voltmeter, voltmeter switch, and series regulating resistance. The side ones had fuses and double-pole switches to put either dynamo on to the arc circuit, an exciting circuit switch so as to prevent extra current in the magnet coils, and field regulating resistance switch. For the private lighting there were five alternator panels, as shown on the right-hand board. The first four each had an ammeter, fuse, double-pole switch to connect any alternator to the omnibus bars, fuse, field-magnet switch, and field-magnet regulator. The latter could be clutched to a horizontal shaft, so that all four fields could be regulated together after preliminary independent adjustment. The fifth panel carried a main ammeter and a voltmeter in the omnibus bar, machine voltmeter and switch for connecting it to any machine, and synchronising switches. There were seven feeder panels, carrying an ammeter, fuse, double-pole switch, and fuse. There were two exciter panels to the right of the smaller boards; each carried two ammeters, a voltmeter and its switch, two double-pole switches to put either dynamo on to exciting circuit, shunt breaking circuit,

Digitized by Google

regulating switch, and fuses. The instruments, with the exception of two Swinburne electrostatic voltmeters on the high-pressure alternate-current circuits, were of the Siemens type.

The feeder mains were carried to seven sub-stations in different parts of the parish. The feeders were of Siemens's concentric type, insulated with specially-treated fibrous material, cased in cold-drawn continuous lead pipe, served, sheathed with iron bands, served and compounded, and laid direct in the ground. The iron armour was so strong that a pick could not go through it. The cable was as cheap and as good as any in the market. There were six sizes of feeders, cross-sections of each of which are shown in Figs. 4 and 5, the conductors varying, according to length, from ·075 square inch to ·02 square inch. The

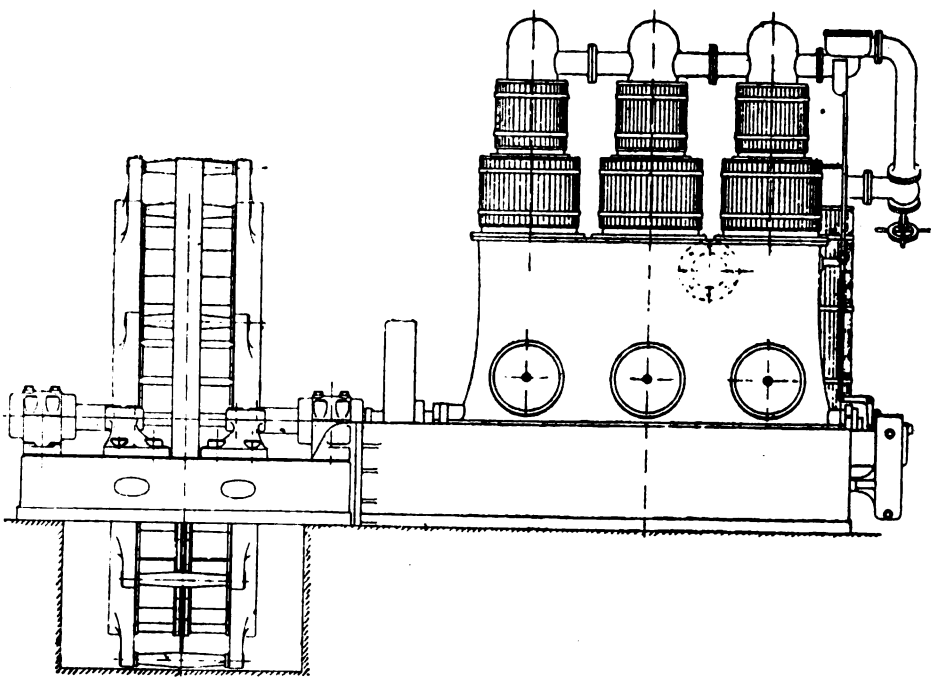


FIG. 1.—Front Elevation of Siemens Alternator and Willans Engine.

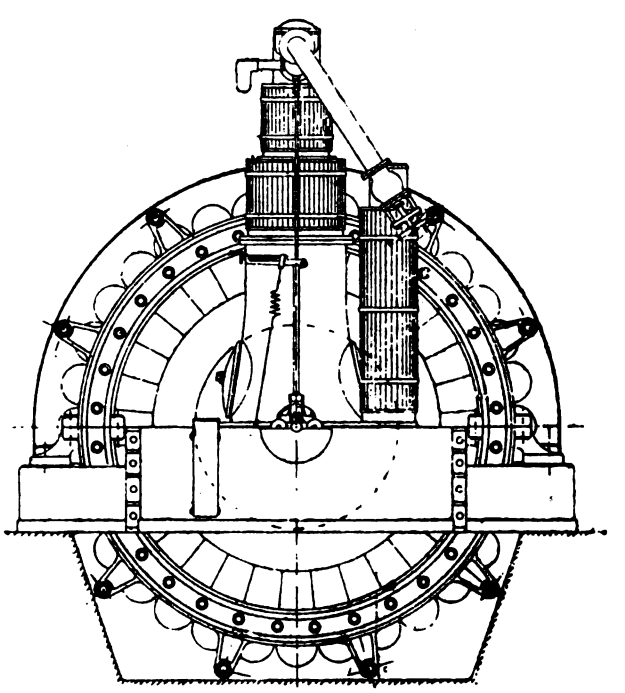

FIG. 2.—End Elevation of Willans Engine and Siemens Alternator.

feeders were connected in the sub-station to Siemens transformers, which converted the current from 2,000 to 105 volts, at which pressure customers were supplied from low-tension mains, similar to the high-tension mains, but not so highly insulated. Sections of these mains are shown in Fig. 6. The insulation resistance of these mains was 1,000 megohms per mile at 60deg. F. The arc lamps were of Siemens band type, double carbon for 10 amperes. They were arranged in globular lanterns with drooping bracket on the top of ornamental iron posts, the centre of the lantern being 22ft. from the ground. A double-pole switch was provided in the base of the post for disconnecting the lamp.

The sub-stations, one of which is shown in cross-section in Fig. 7, consist of small brick chambers, 6ft. by 5ft., built under the pavement, access being obtained through a small manhole in the top. Each sub-station contained two 25-kilowatt transformers, a high-tension fuseboard, and a low-tension switchboard. The two primaries of the transformers were in parallel on the feeder, the current passing through the switch and fuses shown on the right of the cross-section. The two secondaries were in series across the extreme conductors of the network, the middle point being joined to the neutral wire. The number of distributing mains passing out of the sub-station varied from three to five, according to the situation of the sub-station, the current passing through double-pole switches and fuses. The reduction of the current is from 2,000 volts to 105 volts between the outer and neutral wires. The distributing mains from the low-pressure switchboard were so arranged that the supply to any length of distributing-main between two sub-stations could be cut off for the purpose of connecting customers without interfering with any other part of the system. Each sub-station would supply 1,430 8-c.p. lamps. The total length of feeder main was a little more than 3½ miles, and would carry current for the supply of 17,000 8-c.p. lamps. The total length of low-tension main was 3½ miles, and this was sufficient to energise 10,000 8-c.p. lamps.

"Turning now to the question of public lighting," Mr. Preece said, "I may mention that we have erected 26 arc lamps in the main thoroughfare—Finchley-road. I have always been an advocate of street-lighting, but only on a limited scale, and then as well as you can. The great advantage of the use of the electric light for street illumination is that it is an excellent advertisement; it attracts people. In Bristol it is remarkable. The whole of the main thoroughfare from the road leading to the railway station from the town to Victoria Hotel, Clifton, has been lighted by 100 lamps. Now there are 33 per cent. of the shops on that route lighted by electricity; in other parts it is scarcely 5 per cent. That is due very largely to the introduction of the electric light on a brilliant scale. We intend to do the same here.

"I am perfectly certain that this industry in Hampstead is going to be financially a very great success, and I am quite satisfied there will not be any demand upon the rates for any assistance. I think we shall pay our way for further expenses on the borrowed money the first year. We have only been open four weeks. We commenced with 2,176 lamps fixed, we have since added 1,218, and we have orders and authority, and have given instructions, to carry out mains and arrangements for a further 4,475 lamps. Thus, in one month we have got a load of 7,869 lamps, and we only started with the idea of getting 10,000 lamps in two years. I am, however, now impressed that we shall have 20,000 lamps in 12 months.

"The curve, Fig. 8, which indicates the load on October 29, shows the way in which the current is distributed. This is the greatest difficulty. You have between the hours of 4 p.m. and 12 p.m. a very good load—a paying load—but during the rest of the 24 hours you have practically nothing. Now, at Worcester we are trying very important experiments. We have some water power, and we are going to use this water power during the day in work-

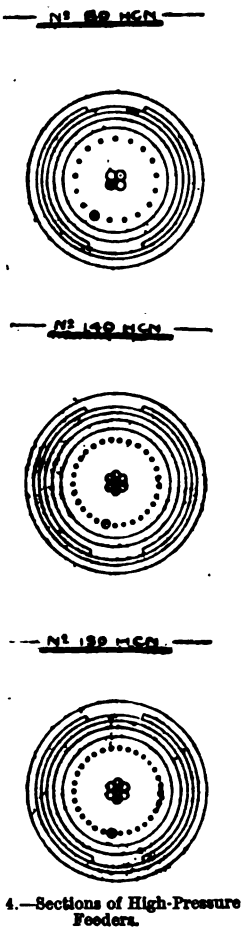

FIG. 4.—Sections of High-Pressure Feeders.

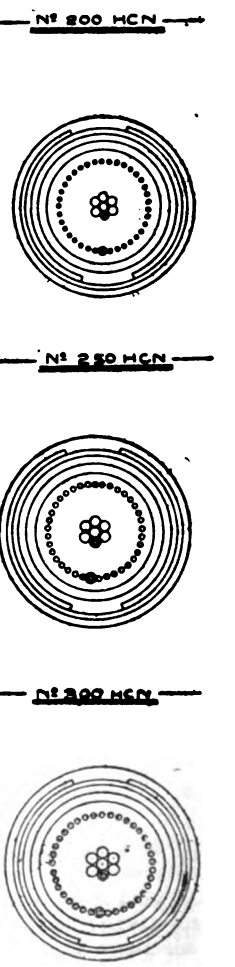

FIG. 5.—Sections of High-Pressure Feeders.

ing pumps at the waterworks and also in pumping sewage to a higher level. The result will be this—that we shall have during the day a load that will compare very favourable with a night load, and we shall have a long continuous curve

Digitized by Google

that will enable us to pay our working expenses night and day. The point is this—whether it is not possible to utilise the current for power purposes during the day and reduce the cost of the light; because if you reduce your expenses during the day you relieve the night load of the cost of this heavy expense. We are quite as successful in

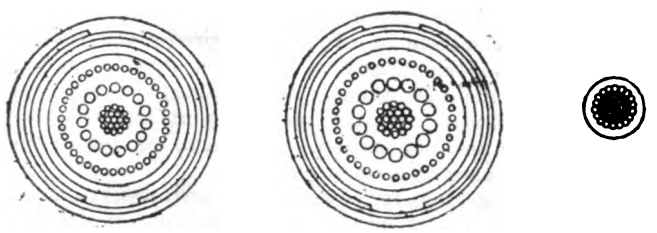

FIG. 6.—Sections of Triple Concentric Distributing Mains, and Section of Arc Light Cable

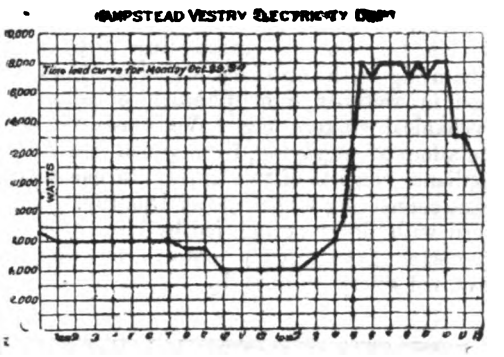

FIG. 8.—Time Load Curve for Monday, Oct. 29, 1894.

Worcester as here. They started Worcester with an exhibition, and with that and the street-lighting and the local exhibits, the station was thoroughly well advertised, and the people are rapidly making applications for the light. You will be glad to hear we have been within our estimates at Hampstead; more than that, we are under our

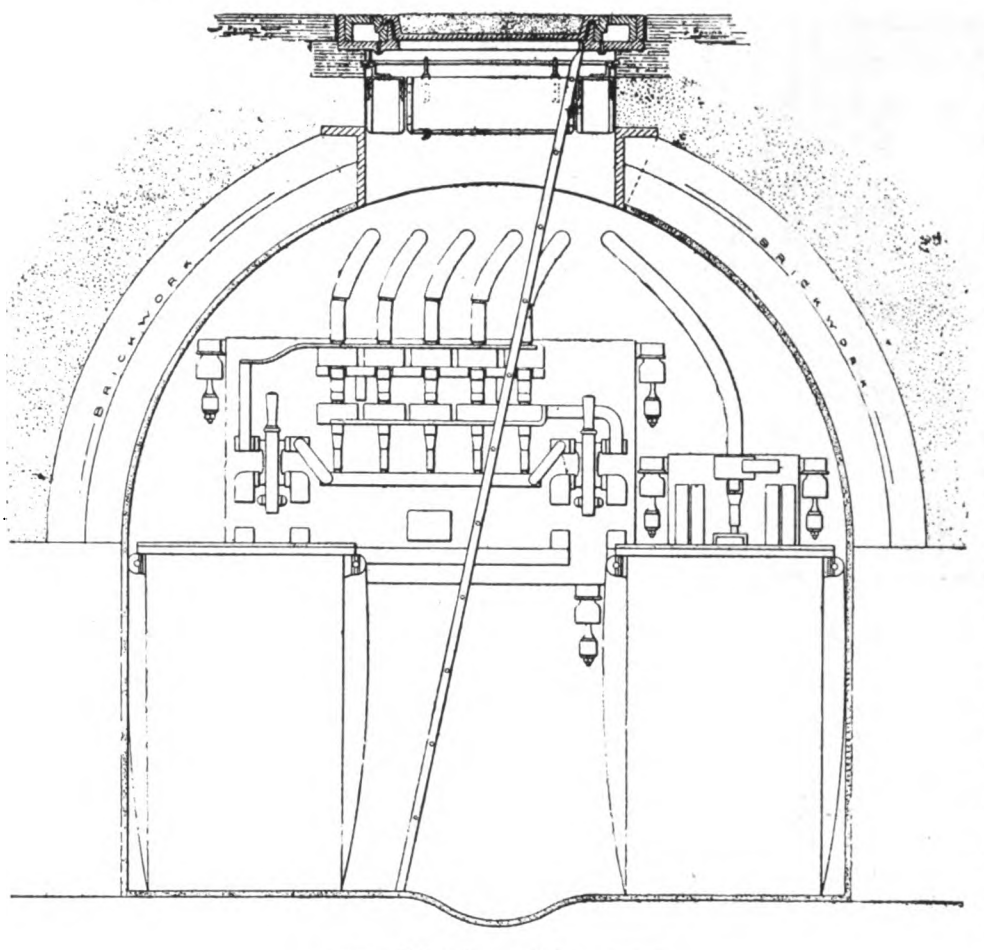

FIG. 7.—Elevation of Sub-Transformer Station.

estimates. The cost of the station has approximately been £30,000, and the charge for current is on a sliding scale, ranging from 6d. to 4d. per unit."

The PRESIDENT (Mr. A. M. Fowler, C.E.) proposed a vote of thanks to Mr. Preece for his interesting paper, which was given unanimously.

The members then inspected the station, and subsequently adjourned to the next meeting at Middlesbrough.

Birmingham.—The new meat market and slaughter-houses are to be lighted by electricity.

ELECTRICITY FROM GAS.

At more than one electric supply station or electricity works the total cost of developing energy has already been brought down to a point but little in excess of Mr. Crompton's ideal figures, allowing a fair but not extortionate amount for management and other standing charges: the item of fuel consumption, however, has yet maintained an excessive degree, and appears likely to do so for ever, if the present system of steam generating be employed. The prospects and capabilities of gas motors are therefore well deserving of examination with a view of ascertaining the development which they might attain under careful use when properly designed and worked.

Our readers are, of course, familiar with the ingenious and far-sighted project planned out by Mr. B. H. Thwaite some time ago with the idea of developing electric energy at the coalfields of South Yorkshire or Derbyshire, and transmitting to the Metropolis at high pressures for service in the thousand and one directions capable of employing electric light and power in London. The gigantic nature of this project—gigantic at least to our somewhat stunted ideas of to-day—is alone sufficient to cause hesitation on the part of the various interests concerned with regard to its adoption, though at no distant date the matter will without doubt come up for serious consideration and discussion of detail.

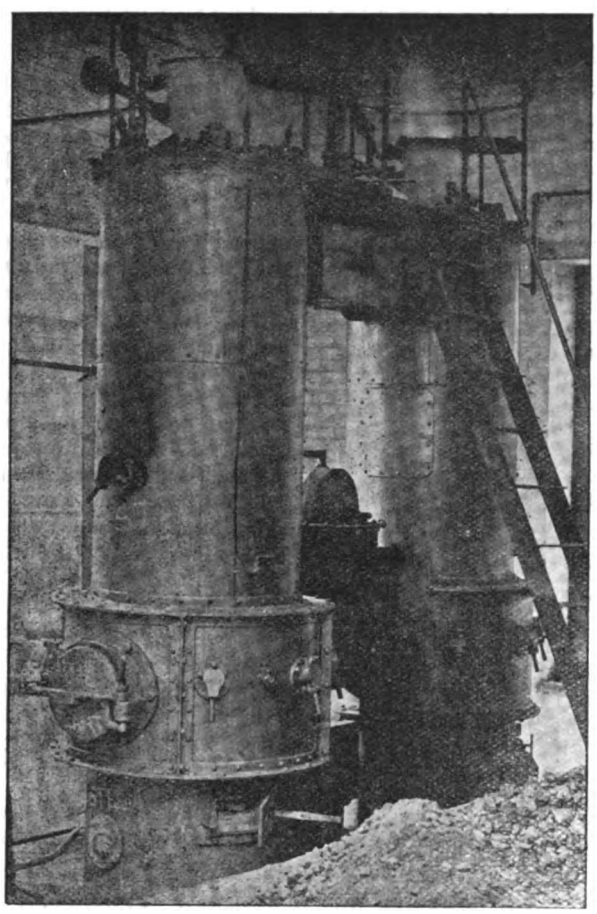
At present, however, the field of gas generation and use appears to offer more opportunities for development on a reasonably large scale. There is, unfortunately, perhaps, no immediate prospect of turning our coalfields into vast gasworks, where gas-engines and dynamos supply the leading centres of population with electric energy for all purposes, and Mr. Thwaite has therefore concentrated his attention upon proving to the satisfaction of electrical engineers that they may effect a considerable saving in their coal bill by turning it into gas for use in gas-engines rather than burn it under steam-boilers, which even at their best are excessively inefficient.

We have just lately had an opportunity of inspecting the system and apparatus devised by Mr. Thwaite for this purpose, and now publish a brief notice of the same, with the intention later on of giving our readers full details in

Digitized by Google

an illustrated account of a typical plant in actual work. At present the matter must be deal with more or less theoretically.

It is, of course, tolerably easy to make good gas from anthracite fuel, and Mr. Thwaite some time ago developed an experimental plant for showing this, and proving the great economy in fuel to be obtained from using gas motors rather than steam-engines: he has now added to this by similarly completing plant suitable for gas generating with ordinary steam coal, such as would be used in water-tube or Lancashire boilers, equipped with mechanical stokers, etc. We illustrate the generator in the annexed engraving, from which it will be seen that the appliance consists of two upright furnaces with a horizontal cross connecting chamber at the top. The furnaces are lined with firebrick and fed by blast from a fan operated by means of an electric motor. The direction of blast is reversed every minute by means of an automatic valve



The Thwaite Steam Coal Gas Generator, for driving Gas-engines.

arrangement, based on the principle of balanced water-tanks. There are no bottoms or grates to the furnaces, but the inner fireclay lining is widened out near the base so as to constrict the interior space. Underneath each furnace is a water seal, through which the gas passes, and into which fall the cinders or pieces of unburnt fuel. The latter are raked out from the front, and used again. The furnaces are fed through hoppers at the top.

We append an analysis of the gas produced in this apparatus, as determined by Prof. Vivian B. Lewes a few weeks ago, from ordinary steam coal.

	From generator.		From main after purifiers.
Sulphuretted hydrogen ..... Carbon dioxide	11·16	.....	11·83
Oxygen	0·00	.....	0·00
Unsaturated hydrocarbons	0·16	.....	0·00
Saturated hydrocarbons	4·20	.....	4·10
Carbon monoxide	18·00	.....	17·16
Hydrogen	7·25	.....	7·33
Nitrogen	59·23	.....	59·58
	100·00	.....	100·00

Other analyses have given a proportion of 21 per cent. for the carbon monoxide, whilst the average of the carbon dioxide has been 4½ per cent., one determination by Mr. H. Allen showing only 1·5 per cent. In the experimental plant the gas is taken through the usual series of purifying and scrubbing devices, and stored in a holder, whence it is drawn for use in a gas-engine of 20 b.h.p. operating one of Clarke, Chapman, and Co.'s dynamos. The producer illustrated, however, would serve for three or four such plants, and Mr. Thwaite claims actual results twice or three times those obtainable from a given weight of coal burnt in a good boiler supplying a compound condensing engine.

Certainly the arrangements for testing the plant at every possible stage—both chemically, mechanically, and electrically—are as complete as could be desired; the results from this arrangement may be depended upon as being reliable, and such as should be obtained under good management under ordinary conditions at any time or place. They are not merely theoretical, or based on laboratory working on a small scale.

Two other ingenious improvements at least deserve mention as being employed in this plant. One consists of a flat sawdust scrubber, placed vertically on edge to catch the tar which would otherwise foul the pipes leading the gas from the producer to the holder. This appliance somewhat resembles a sandwich, where two strainer-plates represent the bread and a layer of sawdust the meat; it is very easily taken down for renewal of the sawdust at regular intervals, and seems to fulfil its purpose admirably. The amount of tar actually passing into circulation is not very great, however, as the reversal of blast through the producer furnaces carries the gas through incandescent fuel, and practically burns out all the tar and other heavy compounds.

The second item worth notice is a little arrangement attached to the gas-engine, by means of which a tiny piston, acting in a small cylinder connected with the main engine cylinder, actuates a needle so as to punctuate a paper strip at every cylinder explosion. A record is kept of all the explosions, showing at once when the engine misses—an important matter for carrying out complete and satisfactory tests.

As stated, we hope later on to give more particulars of the plant with the results of tests undertaken by independent and responsible authorities.

CITY AND GUILDS OF LONDON INSTITUTE.

LECTURE X.—THE CONSTRUCTION AND ACTION OF ELECTRIC BELLS—THE ARRANGEMENTS OF BATTERY CELLS, AND OF CIRCUITS FOR BELLS.

(Specially contributed.)

Bell Circuits.—The different requirements in practice makes electric bell circuits a somewhat interesting study. It will be impossible for me here to describe many of the problems which arise, but a careful study of the simpler cases should enable you to solve questions relating to more complex cases.

Simple Bell Circuit.—The simplest case of all is when one push is used with one bell in circuit, Fig. 1. Here

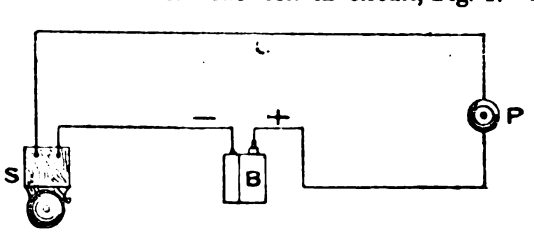


FIG. 1.

battery, bell, and push are in series in the circuit. As soon as the circuit is completed the bells rings.

It is often convenient to be able to ring a particular bell from any one of two or three or more pushes. Suppose, for example, you have to provide for a large dining-room. The object being to save trouble, you may put two or three or more pushes in parallel with each other, as in Fig. 2, and the bell will ring by making contact with either push.

Digitized by Google

It is quite common to arrange a push on the dining-table. So long as such a push is in parallel with the ordinary wall push it will ring the same bell. You can see from the diagram how the circuit is completed by pressing any one of the parallel pushes.

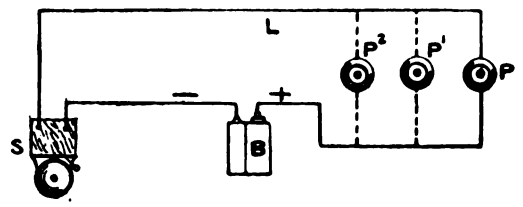

FIG. 2.

Here, then, we have several pushes to ring one bell, but the ringing of several bells from one push is as convenient as what we have just mentioned. Suppose a number of workmen's rooms, or, better, suppose a fire station with men in several rooms, it requires a bell in each room to rouse the men, and to rouse them as quickly as possible the bells should all ring together. There are two ways of arranging such bells—in parallel and in series—whereby each bell is rung by pressing one push. Let us arrange them in

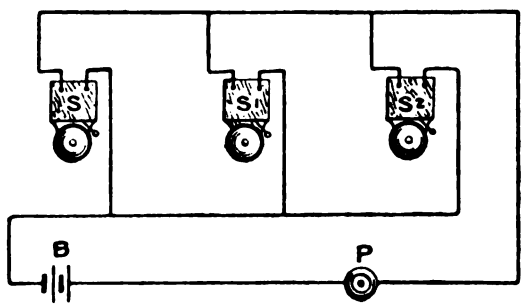

FIG. 3.

parallel first, as in Fig. 3. On pressing the push, P, you see the circuit is completed and the bells, S, S_1, and S_2, ring.

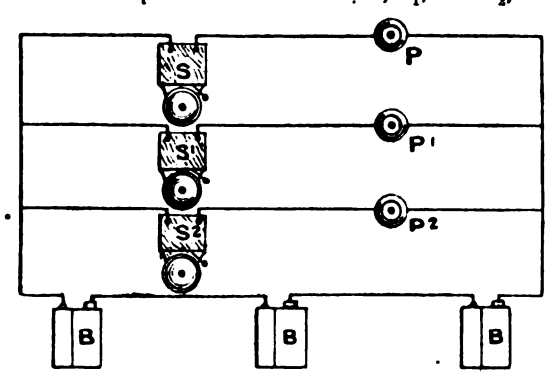

FIG. 4.

If we arrange a bell and its push in parallel with another bell and its push, and so on, as in Fig. 4, then the bell S answers to its own push, P, but not to P_1 or P_2, and bell S_1 answers to its push, P_1, and not to any other, although the whole of the bells may be worked from one battery. The number of cells in the battery indicated on the diagram is of no import. The number will always depend upon the particular circuit you are dealing with.

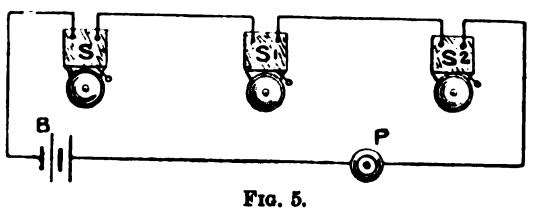

FIG. 5.

I have just said several bells can be placed in series and worked from one push, Fig. 5. This arrangement necessitates more battery power, and ofttimes a different type of bell. A single-stroke bell, however, does very well for series work. You at once see that if we add these in series the resistance of the circuit is increased, hence the necessity for greater battery power. If we try to use trembling bells in series we may by a lucky accident get a result, but a good result will not be obtained by design. The cause of a variable result is that the bells are not usually exactly similar, and do not break circuit at the same time. To meet this difficulty, special bells are made, and when these are used in series the circuit is never broken, but a shunt circuit of much lower resistance than the magnet circuit is obtained, as will be seen by an examination of Fig. 6. Here the line wire W may come from another bell, as line wire W_1 may go to another bell. When the current comes to terminal T it has no road by C, A, G, E to T_1, because of the air-space between C and the screw E, but the

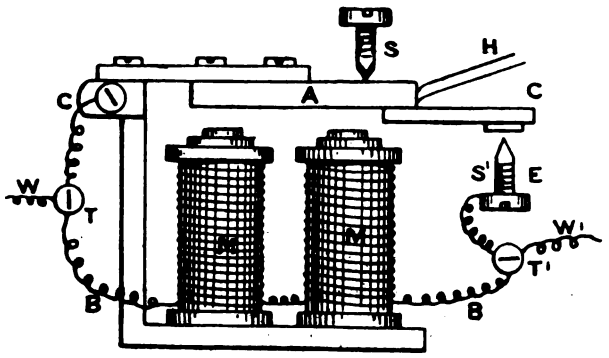

FIG. 6.

magnet cores becoming magnetised by the current pull the armature, A, and cause C to come into contact with E, thus providing a path of low resistance from T through the armature and screw S_1 to T_1. The larger part of the current goes through this path, and so on to the next bell. On the armature going back to its original position to the stop-screw, S, the branch circuit is broken, so that no current can go in that direction. The armature is again pulled by the magnet, and the cycle of operations goes round once more, and so on till the push is freed altogether.

Earth.—Sometimes, instead of having the whole apparatus connected by wires, a part of the circuit is completed by means of the earth. It has long been known that earth, and especially damp earth, is a conductor, and because of its saving metal it is, as I say, often used in place of part of the metallic circuit. One difficulty in using earth is to get a good contact, and to ensure this the metallic portion of the circuit is connected to the gas or water pipes whenever this can be done conveniently. These pipes come into contact with the surrounding earth over large surfaces, and so make good contact. When pipes are not available the wires are fastened to metal plates, which are buried in the most suitable ground that can be found. Fig. 7 shows a circuit thus completed. On the diagram, E E represent the earth connections, whether to pipes or plates. It is very seldom that a circuit partly completed by earth is as good as one wholly metallic.

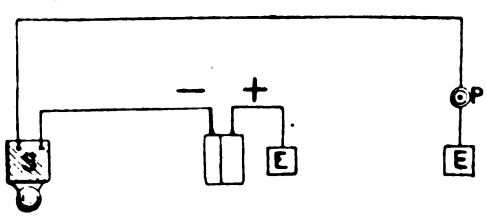

FIG. 7.

Relay.—You will readily understand that the motion of the armature of an electromagnet may be utilised for many purposes besides actuating the hammer of a bell. In the bell just mentioned, its motion is used to form a second path for the current. Similarly, the motion of an armature may be utilised to complete the circuit of a perfectly independent battery, and is so in the apparatus, Fig. 8. Here we may suppose the original circuit to have too great resistance, and too great leakage (for, as we shall see later on, the current leaks whenever it has a chance), for one battery, and so we arrange a local battery having the bell to be rung in its circuit. The push of the local circuit, or what answers to it, is worked by the armature of an electro-

Digitized by Google

magnet. In the diagram, Fig. 8, we can trace the two circuits. We have first the circuit of battery B, which goes through push, P, along the line to the magnet, M, and back from the magnet to the battery. Suppose the circuit completed by pressing P, then a current goes round the magnet coils, and the armature is pulled from the upper stop terminal, which is insulated from the pillar on which it is fastened, to the lower terminal, which is not so insulated. Consider now the circuit of the second battery. When the armature is against the upper terminal, the circuit is incomplete. Trace the course of the circuit: it goes from the carbon terminal by the line through the bell to the post carrying the two terminals, upper and lower.

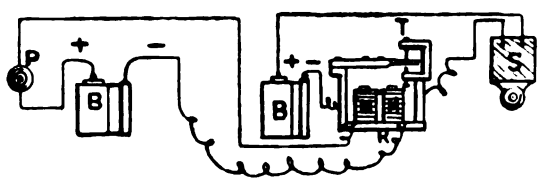

FIG. 8.

The post is also insulated from the framework of the relay, so that the circuit is incomplete either way of the post when the armature is up, for above it is insulated from the armature, and below from the frame. With the armature down the case is different, and the circuit is closed through post and armature to the other pole of the battery. In this arrangement the original battery, whose circuit is completed by the push, P, merely acts to complete the local circuit, and the local battery is the one that causes the bell to ring.

Signalling in Two Directions.—Fig. 9 shows one method of connecting two bells so as to be able to ring in

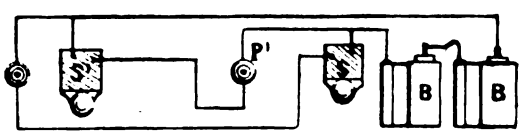

FIG. 9.

either direction with one battery only. In this case we employ three wires, but a careful study of the drawing will show that this is merely a modification of the arrangement in Fig. 4. The length or the position of the wires makes no difference to the system of arrangement, though it may make a difference as to the battery power required. Thus to signal in two directions with one battery, all we have to do is to be careful to arrange one push and its bell in parallel with the second push and its bell. One push may be at Charing Cross and its bell at Oxford, while the second push may be at Oxford and its bell at Charing Cross. Fig. 10 shows another way of

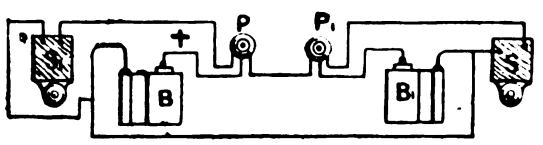

FIG. 10.

signalling in two directions, but here we have two batteries, and must also have special double-contact pushes. I think, however, a careful study of the various bell circuits mentioned will now give you a fair idea of how this kind of work is done.

MECHANICAL TRACTION FOR TRAMWAYS.

(Concluded from page 502.)

From the question of capital outlay, M. de Marchena proceeds to consider the working expenses of tramways operated on the overhead wire system; the chief examples upon which he bases conclusions are drawn from the United States, where, of course, the greatest experience of these lines has been obtained. He finds, however, enormous differences in financial results, owing without doubt to the varied circumstances under which the lines are operated, involving fundamental differences in extent of network, amount of traffic, price of coal and labour, etc. He ventures to give several tables showing the apportionment of working cost—the first of these is based upon official reports from the Cincinnati Tramway Company and the New York Edison Company, and it is as follows:

	Pence per car mile. Cincinnati Tramways.	Edison Company.
Maintenance of line and station	·064	·240
Maintenance of rolling-stock	·704	·976
Motive power	1·632	1·056
Staff	1·152	1·072
Totals	3·552	3·344

These figures refer to the smaller type of cars weighing four tons empty, from 15 to 20 being on the line simultaneously, making from 100 to 115 miles each per day.

In a second table the author quotes some figures from the well-known trolley system of Boston, though his information is no more recent than the year 1891. At that time there were 125 miles of track operated, with 500 cars in service, of a larger and more powerful type than those already dealt with, since they weigh from six to eight tons empty, and attain a daily average journey of about 100 miles each.

	Cost in pence per car mile— April.	May.	June.	July.
Motive power	3·840	4·256	3·648	3·488
Maintenance	·688	·656	·592	·576
Staff	3·648	3·664	3·616	3·456
Repairs	·368	·448	·080	·064
Miscellaneous	2·304	2·272	2·224	2·624
Totals	10·848	11·296	10·160	10·208

The third and last table which the author quotes from American sources is based upon the figures presented to the Street Railway Convention at Pittsburg in 1891, and gives the results shown on 22 overhead trolley-wire systems, having a total length of nearly 200 miles. The various lines were said to range from 3½ to 50 miles in length, having from five to forty cars in operation at a time, and attaining a daily car mileage of from 70 to 150 miles.

	Cost in pence per car mile. Maximum.	Minimum.
Total expenses	11·4032	3·8640
Maintenance of line and way	·9232	·0496
,, overhead system	·4720	·0048
,, station	·4272	·0256
,, rolling-stock	2·5984	·2928
Motive power: labour and fuel	2·4560	·2384
Staff and supervision	4·6976	1·3584
General expenses	1·4640	·3920

According to these figures, the average amount of traction expenses properly so called would be as follows:

	Pence per car mile.
Maintenance of line and station	·24
Motive power: wages and fuel	·976
Maintenance of rolling-stock	1·056
Staff	1·056
Total	3·328

The cost of coal varies in these examples from 4s. 2d. to 15s. 10d. per ton, and labour is taken at 5d. to 10d. per hour. No sinking fund is allowed for in the figures, either to cover the outlay upon fixed plant or rolling-stock. In practice an amount of 10 per cent. on the boilers, engines, overhead conductors, and motors would prove sufficient for this purpose, whilst an allowance of 5 per cent. only need be made for the dynamo generators. This would bring up the cost per car mile to about 4·4d.

Turning to the chief European lines, the author considers rightly that they have as yet been established for too short a period to draw adequate conclusions of their real possibilities from a financial standpoint, but still the figures derived from three conductor wire systems are, he thinks, worth noting. These relate to the lines at Vevey-Montreux, Clermont-Ferrand, and Budapest. The first of these is operated by water power, the others by steam, and the Budapest line, as will be remembered, has an *underground* instead of *overhead* conductor.

	Cost per car mile in pence. Vevey.	Clermont.	Buda.
Maintenance, etc., of way and station	·144	·192	·114
Motive power	1·216	1·648	1·136
Maintenance, etc., of rolling-stock	·912	·704	1·152
Staff	·992	1·296	·736
	3·264	3·840	3·168

Digitized by Google

As a final instance of the financial results obtained from electric traction, the author gives some figures of working costs, etc., on the Halle tramways, where horses were replaced by electric motors in the year 1891. The length of line involved only amounts to about 4¾ miles, but numerous grades of 2·5 up to 4·8 per cent. require to be traversed. Comparing the costs of animal *versus* mechanical traction, the author obtains the following results :

	Horses.	Electric motors.
Number of car miles	472,200	499,652
	Working expenses in pence per car mile.	
Staff	1·4288	1·3424
General charges	·3088	·3632
Maintenance, etc., of line and fixed plant	·0512	·0656
Maintenance of rolling-stock	·1232	·2144
Horses and harness	1·5552	—
Motive power	—	·4704
Total	3·4672	2·4560

In the first case, the receipts per car mile were only 3·3d., leaving a debit balance to show that the lines were worked at a loss by horse traction, but since the introduction of electric motor cars the receipts have gone up to considerably over 4d. per car mile, thus proving the change to be extremely profitable. The cars used at Halle weigh about six tons empty, and have a seating capacity for 34 passengers.

At Marseilles the total cost of working ranges from 4d. to 4½d. per car mile. The rolling-stock consists of cars weighing about 6½ tons empty, with seats for 50 persons each. The Milan tramway is worked at about 4½d. per car mile; whilst at Dresden, where the line is tolerably level throughout, and where current is obtained from the central electricity works, the cost is only about 3·12d. per per car mile for small cars containing 28 or 30 individuals. On the Liverpool Overhead Railway it is stated to vary from 3·36d. to 3·84d. per car mile, each car holding 56 persons.

None of these rates, it will be understood, include an allowance for amortisation or sinking fund. The usual cost of working ranges between 4d. and 5d. per car mile, including maintenance, etc., of the generating station, the line, motors and cars, drivers' and conductors' wages, etc. Provision for a sinking fund would add at least 1·3d. per car mile to this total, allowing 10 per cent. for the fixed plant and car equipments on a total outlay of £1,200 to £1,400 per car on line with an annual service of, say, 30,000 car miles, and 5 per cent. on the overhead line equipment with an annual mileage of 100,000 per mile of line. The entire question of amortisation, however, can hardly be settled as yet, the experience of electric tramway authorities in Europe being still too limited to enable a satisfactory conclusion to be drawn.

The author then follows with a similar treatment of electric accumulator traction, but in view of the admittedly imperfect condition of secondary batteries for tramway use it seems hardly necessary to deal with the matter at serious length. We may, however, do so when occasion allows, in order to bring the matter up to date and arrive at some useful results.

SOUTHPORT ELECTRICITY WORKS.

The opening of the municipal electricity works, which we described in our last issue, was celebrated by a luncheon given at the Town Hall. Subsequently a visit was paid to the works at Crowlands for the purpose of putting the machinery in motion. The Mayor and Mayoress were accompanied in carriages by a number of ladies and gentlemen present at the luncheon. There were also present, among others, at the works, Mr. A. Siemens (Messrs. Siemens and Co., London), Dr. Hopkinson (Messrs. Mather and Platt, Manchester), Mr. J. B. Atherton (British Insulated Wire Company, Prescot), Mr. Hesketh (electrical engineer, Blackpool), and others. The works were designed by Mr. G. Wilkinson, M.I.E.E., electrical engineer to the Corporation, who, however, had to resign through failing health, and his place was taken by Mr. Arthur Ellis, M.I.E.E., by whom the work has now been brought to a successful issue. Both these gentlemen were present at the ceremony.

The **Mayor**, standing in front of the switchboard, said they were met to start the machinery in the Southport electrical works. Electricity was becoming more and more sought after, and was becoming more and more useful. It was used for house-lighting, street-lighting, and illuminations; it was used for cooking by the Queen at Osborne, and in other places; it was used for motive purposes, and for medical and dental purposes.

Alderman Hacking said that two years had been spent over that work, and although it might seem a long time, if they looked they would find other towns in pretty much the same position as Southport. When an electric installation was decided upon two years ago very few of the members of the committee knew anything at all about the matter; they had to grope their way, but now the work to be done by the committee would be very much easier. They appointed an electrical engineer, Mr. Wilkinson, and the plan they had carried out was his plan, except that the committee decided on one high-tension cable, where Mr. Wilkinson recommended two, so that one might be ready for use if any accident happened to the other. They had started with an expenditure of £13,000; that was not a large sum when they considered the miles of cable laid, the size of the buildings boilers, engines, and dynamos, and he wished to say that in every particular the contractors had given the utmost satisfaction, while the work of their own men had been most praiseworthy. The installation plant gave an equivalent of 4,200 8-c.p. lamps, though the cables and boilers were sufficient for a production of twice the present quantity. They had applications from private customers for 3,586 lights, and 1,445 for the Municipal Buildings, making 5,031 in all, so that it would be necessary for them to get more engines and more power very soon. As for street-lighting, the committee would be quite ready to take up that question if the ratepayers, after reckoning the cost, desired it.

Councillor Hesford supported Alderman Hacking's remarks as to the excellence of the work which had been done by the contractors and the Corporation electrical engineer.

The **Mayor** said it was greatly to be regretted that Mr. Wilkinson had to retire from ill-health, and their thanks were due to Mr. Ellis for his exertions to get the installation ready that day.

Dr. Hopkinson said it was very satisfactory to know that many of the Lancashire towns, although they had been rather slow in taking up the electric light, now possessed their own installations. There was an enormous scope for electricity in the future.

Mr. A. Siemens (London), speaking of the comparative cost of gas and electricity, said he had kept his accounts very carefully for five years, three with gas and two with electricity, and the total bill each year did not vary more than 10s. per light with gas at 3s. per 1,000ft., and electrical energy at 8d. per Board of Trade unit. The great point was to have the switch near the entrance to a room, and for the current to be turned on only when actually required.

Alderman Hacking then started the engines, after which the current was switched on to the mains, and the lamps lighted amid cheers. This over, the party returned to the Town Hall for tea.

A large concourse of people assembled to witness the turning on of the electric light in front of the Municipal Buildings. Punctual to the hour—six o'clock—the Mayor, wearing his robes of office, escorted the Mayoress from the mayor's parlour to the Town Hall steps, the members of the Council and others following. They were cordially greeted by the crowd.

Alderman Hacking (the chairman of the Gas Committee) briefly introduced

His Worship, who, pointing to the switchboard before him, said that there were six handles there with which to turn on the electric light. He would first turn on the two arc lights in front of the Town Hall. Having done so, he then turned on the lights on the front of the Town Hall.

The illumination of the front of the Municipal Buildings was on a scale commensurate with the importance of the occasion. As to the number of lights in use, there were 350 16-c.p. lamps on the front of the Cambridge Hall, 250 on the front of the Town Hall, and 450 scattered over the fountains and grounds. On the Town Hall there was a line of lights on the level of the first storey, with a double line on the balcony over the entrance, while on the top of the building were two lines. On the Town Hall steps were two 500-c.p. lamps. Seeing that only nine days had been allowed for this work, it was carried out with dispatch. The contract was in the hands of Messrs. Calvert and Co., of 24, Exchange-buildings, Manchester, and the execution of the work was supervised by Mr. Chas. Alcock.

In the Town Hall the work was practically completed in the Council-chamber, the mayor's parlour, the town clerk's offices, the main staircase, the committee-rooms, and the large hall. In the Council-chamber there are 48 16-c.p. lamps fitted in the gas pendants; in the mayor's parlour are 12 ornamental cord pendants; in the town clerk's office there are five lights on one pendant; and in the deputy town clerk's office one three-light electrolier and two cord pendants. The offices throughout will be fitted with the electric light, mostly by means of cord pendants. In the large hall of the Cambridge Hall, suspended from the centre line of the ceiling, there are seven electroliers, each furnished with 12 16-c.p. lights. In addition, there are five cord pendants of 16-c.p. under the gallery, and eight of similar capacity under the balcony—four on each side. The work in the Town Hall and in the Cambridge Hall has been carried out by Mr. Albert Maund, electrical engineer, of 9, St. James's-street, Southport.

The Explosion in Cannon-street.—Referring to the recen explosion in Cannon-street, Alderman Bell, chairman of the City Sewers Committee, at a meeting of the City Corporation yesterday, stated that the accident was caused by the confusion of two high-pressure cables at Bankside, in consequence of which a current was unintentionally put on to a cable which was touching the ground.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIII. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

HALF TRUTHS.

The *Evening Standard* of Tuesday last had the following leaderette:

"It has been predicted that the development of electricity must in the end transfer manufactures from the plains where they have always flourished hitherto to mountain districts which at present are occupied by sheep and game. The demonstration appeared to be sound. Machinery driven by steam—that is, by coal—never can compete with machinery driven by electricity, if the latter be generated by water power. The cheapest water power is mountain streams. Therefore in the coming time a bold and enterprising manufacturer will set up works on Snowdon or Ben Nevis, or some such lonely eminence, and undersell his comrades at Manchester or Birmingham. They will be compelled to do likewise, and the great seats of industry at present must become a heap of ruins singularly unpicturesque. It was pointed out that the revolution has already began in Switzerland. This uncomfortable forecast seems to be disconcerted by the announcement that they are using artesian wells in Dakota to generate electricity with great success. Artesian wells can be sunk anywhere almost in the lowlands of this country. The expense may be considerable, but compared with the sum needed for transferring a large business to any mountain district it is a trifle. But then, again, if you sink a number of wells in a narrow space they are apt to drain one another. Let us hope all will come right somehow."

There is in this leaderette about as much misinformation as could well be compressed into the space, and yet there is underlying the whole a substratum of truth which makes the publication the more dangerous. Never has the political Press done more damage to an industry than it has to electricity Not because of the desire to do damage; far from it, the desire is just the opposite: but those who write are absolutely ignorant of the subject upon which they write. Anxious to please, the writers in these papers make famous, men who have few or no pretensions to originality, but are possessed of much push and cheek, while the real workers are left without a word of encouragement. What a pity it is that papers of the standing and the circulation of the *Standard* do not promote a specialist to advise on these matters.

Unless memory is wrong, the *Standard* has more than once or twice, or twenty times, called attention to the handicapping of various English industries because of "cost of carriage." Did it not strike the writer of the above leaderette that something besides the generation of power cheaply had an influence upon the question of profitable manufacture. There is a well-known axiom that threatened men live long, and applying this to the threats towards Manchester and Birmingham, it is just possible that the time of the heap of ruins is further off than the *Standard* writer imagines. Just fancy the cost of getting raw cotton to the top of Snowdon, and the cost of distribution of the manufactured article subsequently, and then ask the question whether it conduces to economy to put a

Digitized by Google

factory on Snowdon because of a natural waterfall to supply power. Balance gains against losses, and you will find Manchester and coal winning easily. No, wise writer, the substratum of truth underlying your incorrect statement is the question whether it would pay to generate energy at the natural waterfall and transmit it to such distances as it could be economically used in factories. Norway, Sweden, and Switzerland are not going to become very keen competitors of Manchester unless other factors besides natural waterfalls are favourable.

Similar reasoning may be applied to artesian wells. It may in some cases, generally depending upon geological questions, be possible to utilise the flow of water in artesian wells, but because the geological formation conduces to this in Dakota it does not follow that similar conditions exist in "the lowlands of this country."

The difference between Mark Twain's jumping frog and the *Standard* writer is that the former has too much ballast while the latter is without any. Again we observe what a pity that influential papers should promulgate such utter nonsense.

CONSISTENCY.

Here are samples of the bantam's crow:

Lightning on Folkestone Electric Lighting in the Past:

August 10, 1893.—"A Mr. Mark Parker has been called in to give a report on the electric lighting of Folkestone, and he reckons that £70,000 or £80,000 will have to be expended. I should fancy that Folkestone could make a very good start with £15,000 or £20,000."

August 17, 1893.—"Since I wrote last week I have had the advantage of the perusal of Mr. Mark Parker's report—a very voluminous document. I am glad to see that he freely quotes from these pages, though I feel he would be treating his employers with greater courtesy if he had acknowledged the source of his information. In some parts of the report whole pages are copied from *Lightning* without a single word of acknowledgment. . . . Altogether, I pity the poor unfortunate member of the Electric Lighting Committee who is forced to wade through this Folkestone document. As might be expected from such an inexperienced hand, the latest system of alternating-current distribution is not mentioned."

August 24, 1893.—"The Electric Lighting Committee met on Tuesday to consider Mr. Parker's report; but it is really such a ponderous tome that no one cared to tackle it, and the meeting was adjourned in order that the committee might go into a month's training. . . . I do not know who this Mr. Mark Parker may be that has come out of the *ewigkeit* to compile a treatise on electric lighting for the Town Council, but if the names of Mr. W. H. Preece, Prof. Kennedy, Dr. John Hopkinson, and Mr. Robert Hammond are known to that gentleman, he will be interested to hear that in not one of the schemes recommended by them during this year has the initial cost exceeded £25,000. (*Vide* Kingston, York, Stafford, and Newport.) I should advise the Electric Lighting Committee to make an independent tour of inspection."

Lightning on Folkestone Electric Lighting last week (Nov. 9, 1894):

"Mr. Medhurst is evidently unaware of the fact that when he was at school Mr. Mark Parker was a hard-working electrical engineer, and though when business did not look bright he took up photography as a business, he was simply following in the footsteps of that eminent electrical engineer Mr. J. W. Swan."

THEORY OF TWO AND THREE PHASE MOTORS.

This subject was discussed by Lieut. Samuel Reber at a recent meeting of the American Institute of Electrical Engineers. The author, without attempting a complete mathematical solution, gives an approximate solution in which the change of magnetic properties of the iron and magnetic leakage are neglected, the coefficients of self-induction considered constant, while the mutual induction between the armature and field circuits follows a sine law, and the field is supposed to be without projecting pole-pieces.

The conclusions reached by the author are that the two and three phase motors have in general the same properties, and that the most important relation is that of R to f L; where R is the resistance of the armature; $f = 2\pi$ times the complete periods of armature circuit; and L equals the coefficient of self-induction of one armature circuit. The lower the field armature resistance is, the higher the efficiency of the armature, and the nearer to synchronism is the point of maximum torque. Hence high efficiency motors require a starting resistance, and in such motors the torque can be readily regulated by adjustment of the armature resistance, and we are enabled to throw the point of maximum torque at any speed we desire. It is likewise apparent that the smaller the magnetic leakage the more efficient the motor.

If the frequency is supposed to vary, the speed and output are greatly changed. Increasing the frequency n times in a motor without a condenser, the velocity will be increased n times, the maximum torque is not affected, while the hysteresis is increased n times nearly, the output of the motor will be increased nearly n times if the motor is run at a given percentage of the maximum torque. Hence it is an advantage to increase the frequency till the hysteresis heating becomes too great, or the motor runs too fast. If the efficiency is to be kept constant, the work will then vary as n^2 and the field and armature currents will be increased $\sqrt{n}$ times. Hence, increase in speed gives an advantage in output till the machine begins to overheat. With a condenser the same facts hold, but with this advantage—that an increase in the frequency greatly reduces the size of condenser necessary. A high-frequency motor will weigh less than a low-frequency one. When the clearance is large, the advantage of high-frequency motors is not so decided, and if very large the low-frequency motors are better if weight is no consideration. The higher-frequency motor will contain less iron and more copper. If we vary the size of the motor, keeping the magnetisation constant, output and hysteresis vary directly as the weight, and the heating of the field and armature circuits, directly as the increase of size.

(*j*) *The Action of an Influence Machine, Battery, Direct Current Dynamo, and Alternator.*—It should be remembered that all so-called generators of electricity do not generate electricity at all, their function being to displace it, thus causing a difference of electrical pressure or potential. They are therefore more correctly described as generators of E.M.F.—*i.e.*, a force disturbing, or tending to disturb the even distribution of electricity. In Fig. 9 is represented an influence machine, T+ and T− being its terminals, and C C′ condensers or Leyden jars connected therewith. The inner coatings of C and C′ may be looked upon as part and parcel of the conductors forming the terminals or poles of the machine, brought specially near an earth-connected conductor—*i.e.*, the outer

Digitized by Google

coating of either condenser—thereby greatly increasing the capacity of the terminals. When the machine is worked it may be looked upon as a kind of electric pump, pumping the electricity from the negative terminal, T−, through the machine, and heaping it up on the positive terminal, T+. A difference of potential is consequently gradually created between T+ and T−, and when this becomes sufficiently great, a spark will pass, the surplus on T+ jumping across to fill up the deficit on T−, and equilibrium will be restored. If the condensers be disconnected from the machine, the capacity of the terminals will be greatly decreased, and on working the machine a constant stream of thin sparks will pass from T+ to T−, the fact that there is a very short interval of time between each spark, and the thinness of the same, indicating that very little electricity is required to be displaced in order to give the required potential difference to cause a discharge across the air-gap—*i.e.*, that the capacity of the terminals is very small. When, however, the condensers are connected with the machine, sparks will only pass at intervals, and they will be much thicker

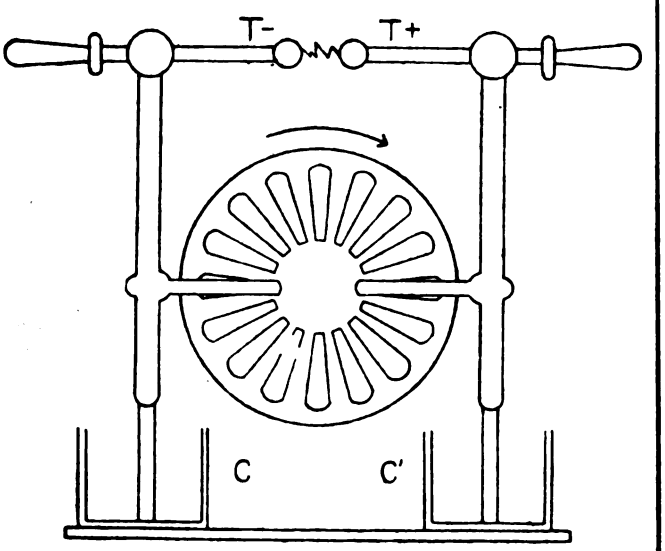

FIG. 9.

sparks, thus indicating that (provided the distance between the terminal knobs be not altered) the potential difference is the same, but the quantity of electricity displaced is much greater, owing to the increased capacity of T+ and T−. The turning of the machine generates an electromotive or "electro-pumping" force, which brings about the displacement of electricity. This electromotive force depends, roughly, on the number and size of the metal sectors, on the quality, thinness, and nearness of the glass discs, and on the rapidity with which they are rotated; and is quite independent of the capacity of the terminals. If the terminal knobs are too far apart, the heaped-up electricity on the + side will overflow, so to speak, and leak back across the plates of the machine, or over the edges of the condensers. The working of the old-fashioned "frictional machines" may be looked upon in the same light, except that their "electro-pumping" action was brought about by the passage of two dissimilar surfaces over each other, and not by influence. In most of these the terminals, or rather terminal (for one, the rubber, was generally connected with earth), was of absurdly small capacity, but this was in some cases slightly increased by adding to the surface of metal connected with the "prime conductor," as it was generally called, thus rendering the machine very cumbersome. In Winter's machine this increase of capacity was effected by placing on the "prime conductor" a metal ring nearly as large in diameter as the glass plate of the machine. This, in virtue of its shape, was supposed to possess superior capacity, whereas any metal body of equal area, such as a sphere, would have answered just as well, and occupied much less room. The capacity of such machines could be greatly increased by attaching the inner coating of a Leyden jar or condenser to the "prime conductor" or terminal, the outer coating, as well as the rubber of the machine, being connected with earth. A primary or secondary cell (or battery) may be looked upon as an electric pump, in which the electromotive or "electro-pumping" force is set up by the chemical action going on within the cell. A dynamo is also an electric pump, whose E.M.F. is due to the movement of conductors and magnetic lines of force across each other. A direct-current dynamo, like a battery, is a pump which works continuously in one direction. An alternator may be likened to a pump exerting its force first in one direction and then in the other, producing a rapid oscillation of electricity in the circuit, instead of a continuous flow in one direction. When a battery or direct-current dynamo is joined up in an incomplete circuit, it may be likened to an air-pump, P−, Fig. 2,* whose inlet and outlet are connected round by a pipe in which is a stopcock, S C; the whole being airtight, and filled with air at the normal pressure. If the stopcock be closed, working the pump will produce a difference of pressure on the two sides of the stopcock, the pressure being greater than the normal on the right-hand side, and less than the normal on the left-hand side; the difference of pressure (indicated in the figure by + and − signs) depending upon the "aeromotive force" of the pump. If the stopcock be opened, there will be a continuous flow of air round the circuit, the rate of flow depending on the "aeromotive force" of the pump, and on the internal diameter and shortness of the pipe circuit. When the battery (or dynamo) is on open circuit, Fig. 10—*i.e.*, when the switch, S (which corresponds with S C in the right-hand figure), is "off" and before the E.M.F. is allowed to act—we may consider that the wires and battery (or dynamo conductors) are imbued with electricity evenly distributed (section *a*). When the E.M.F. acts, the circuits still being open, there is a momentary passage of electricity through the battery (or dynamo), creating a potential difference between the two ends of the circuit; but as the E.M.F. of a battery or ordinary dynamo is only some hundred-thousandths that of an influence machine, there will be practically no spark or other discharge across the air-gap at the switch. When, however, the latter is closed, there will be a continuous flow of electricity round the circuit—the rate of which (in amperes) will be directly proportional to the E.M.F. of the battery or dynamo (in volts), and inversely proportional to the resistance of the circuit (in ohms). Ohm's law, or the law of direct-

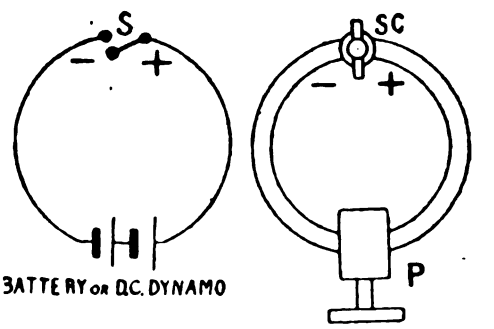

FIG. 10.

current flow in the electric circuit, is comparable with the law of flow of air in the pipe circuit.

(*k*) *The Condenser.*—A condenser may be defined as *a device for increasing the capacity of a conductor by placing it near another conductor connected with earth, or with the other terminal of the circuit containing the source of E.M.F.*

In Fig. 11 I., B is a battery of several cells, G a galvanometer suitable for indicating the passage of transient currents, and K a charge and discharge key. As was explained in the preceding paragraph, when K is depressed, we may suppose that the battery pumps a certain quantity of electricity from left to right until the P.D. between the ends of the circuit + and − is equal to the E.M.F. of the battery. The quantity of electricity that will pass under a given E.M.F. will be proportional to the capacity of the two ends of the circuit, and as this obviously is very small in the present case, the transient flow from left to right, and the return flow (when the key is released) from right to left, will be far too small to affect the galvanometer. The explanation of this return flow is as follows: the E.M.F. of the battery piles up electricity, so to speak, at the right-hand end of the circuit, leaving a deficit at the left-hand end. When the pumping force of the battery is cut out by releasing the key, a transient flow takes place from right to left until equilibrium is restored.

In Fig. 11 II., the two ends of the circuit are bent round so as almost to meet; this will have the effect of slightly increasing their capacity, and with the same E.M.F. there will be a greater transference of electricity before the P.D. between the ends of the circuit becomes equal to the battery E.M.F. The reason of this increased capacity is as follows: let us suppose a slight transference has taken place, there will then be a surplus at + and a deficit at −; the surplus will act influentially across the air-gap, and tend to increase the deficit, and conversely, the − end of the circuit will tend to draw more electricity into the + end. Although the flow to and fro, on depressing and releasing the key, will be greater than in the first case, it will still be far too small to affect the galvanometer.

In Fig. 11 III., the ends of the circuit are laid for some distance side by side. Their capacity will thus be considerably increased, and the transference of electricity greater than in the preceding case; yet even now, unless the galvanometer is

* See remarks on analogies in section (*b*).

Digitized by Google

an extremely delicate one, and a great number of cells are used, the former may not be visibly affected. If, however, the two circuit ends be formed of a considerable length of silk-covered wire wound side by side on a bobbin,* a deflection of the galvanometer will possibly be obtained.

In the fourth case (Fig. 11 IV.) we connect the two ends of the circuit to two flat metal plates (shown edgewise in the figure), say, 2ft. square, brought close together with a sheet of paraffin waxed paper interposed to prevent actual contact. On depressing and releasing the key, equal but opposite deflections of the galvanometer will be obtained, showing that the quantity of electricity displaced by the battery is equal to that which returns when the key is released. The return flow may be accounted for thus: when the pumping force of the battery is removed, the piled up electricity at the + end will flow back until equilibrium is restored. The reason for the great increase of capacity is easy to understand: the greater the extent of surface forming the two ends of the circuit, and the nearer together these surfaces are brought, the greater will be the influential action which brings about the increase of capacity. The effect obtained with two opposing plates of ordinary dimensions is not nearly so great, of course, as would be the case were a telegraph condenser used, owing to the much larger extent of the opposed surfaces in the latter.

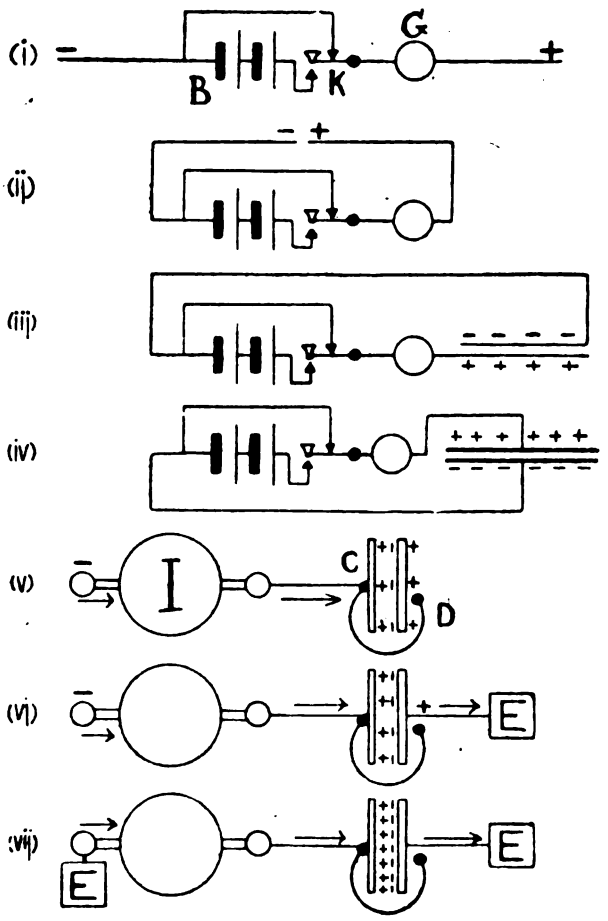

FIG. 11.

Referring to the definition of a condenser at the head of this article, we will now proceed to show that a condenser does not act as such if one coating (or set of coatings) be insulated; also that if the opposite coating be earth connected, and the other end of the circuit containing the source of E.M.F. be insulated, there is only a slight "condensing action." If, however, the other end of the E.M.F. circuit is connected with the opposite coating, either directly or through the earth, the action of the condenser will then be at its best. As a battery and galvanometer would not give any noticeable discharge to illustrate the first two of these cases, we shall employ (Figs. 11 V., 11 VI., and 11 VII.) an influence machine, I, a simple condenser, C, formed of tinfoil sheets on opposite sides of a thin sheet of glass, and discharging tongs, D.

In Fig. 11 V., I is the influence machine "pumping" from left to right: a deficit will consequently be created on the left-hand terminal, and a surplus on the left-hand coating of the condenser. This charge, acting across the dielectric, will influence a deficit on the inner side, and a surplus on the outer side of the right-hand coating. Now, to begin with, the two ends of the E.M.F. circuit are clearly the left-hand terminal of the machine, and the left-hand coating of the condenser: between these, therefore, will be the greatest P.D.

(To be continued.)

* The principle of Langdon-Davies's *phonopore*.

LIGHTING INSTALLATIONS *

BY H A. HENDERSON.

For the purpose of this paper installations may be divided into two classes, good and bad, but I shall divide the latter into two sub-classes—namely: (*a*) installations, which, although they may not be of the best, are still good enough to pass the usual examination nd test of the supply company's inspector; and (*b*) those which do not fulfil this condition. I have not much to say about Class I., except that this quality of installation depends upon three essentials—namely, good supervision, good labour, and good material.

To my mind, the most interesting objects for discussion are included in Class II., so I will at once pass on to these. As we saw that good installations depend upon three essentials, so we may say that any one of these being absent produces a result contained in either sub-class *a* or *b*. First, then, let us briefly touch upon supervision. This is a point upon which I cannot lay too much stress, and I fear it is only too often neglected by just the very class of contractors amongst whom one would expect to find it. The reason of this is not difficult to surmise. It is that the busy contractor cannot spare the time to devote to it that he ought, as he has many enquiries, and special technical work to attend to, which he is unable to trust to his juniors. The immediate effect is that the work being left perhaps under the control of incompetent men—and most of us know what the average wireman does under these circumstances—the installation falls into Class II., and this notwithstanding the fact that the best material may have been supplied. It is, perhaps, unnecessary for me to mention that under these conditions the weak point is, as a rule, bad joints. Bad joints in an installation are, perhaps, the most difficult faults to find out, as one cannot possibly in the course of an inspection pretend to critically examine every one. Generally, the outside appearance is good, and unless the joint be absolutely cut open its weak points are not discovered. There is an example before you of a joint which upon a superficial examination is very good, but it is in reality about as dangerous a combination of unskilled workmanship as one would wish to meet with.

First, we find only one point of contact between the conductors, and this probably rendered bad by the presence of rubber; thus we should be certain to get a heating effect owing to the high resistance. Then instead of stripping the braiding, or outer covering of the wire, back, and leaving the vulcanised rubber to form an insulator, the braiding is carefully bound in on to the conductor, and in case of general dampness would make a fairly easy path for the passage of the current to earth. I may mention that the examples of joints on the table are reproductions of actual ones that I have myself taken out of installations. I am bound, however, to state that these sort of specimens are not often met with now. Out of over 500 installations which I have inspected and tested within the last 18 months, only a small percentage were absolutely bad. I have found that the two most dangerous types of contractor to deal with are the plumbing-electric bell-fitter and the "freshman" at the technical school. Two instances of installations carried out respectively by a plumber and a student will suffice to show what I mean. In the first, one of some 18 or 20 lights, a superficial examination seemed satisfactory. That is, the mains and all easily accessible wires were apparently of good quality. The insulation resistance, however, was below 10 ohms, and a further investigation revealed the fact that ordinary bell-wire of a quality similar to the sample on the table had been used and bedded in new plaster without any casing, tubes, or protection whatever. It was necessary for me to actually dig out the wires before I could discover this. Needless to say, being a very low tender, the contractor lost his money and the confidence of his client.

The second example was a case where the best material had been used and everything done upon the most approved scientific lines, but upon turning on the current the lamps only came up dull red. The reason of this was that the number of lamps being even and on two-light electroliers, they were wired in pairs of two in series, "because," as the contractor informed me, "he could not get four wires down the tube of the fitting"!

Such cases as these are, however, I am happy to state, growing fewer day by day. Before I dismiss this portion of my subject I must just add a word or two upon the various systems of wiring premises. In Manchester we are perhaps more favourably situated than in any other town in England, as we have the alternative of wiring either on the three or five wire systems. The latter plan has been adopted with great success

* Paper read before the Northern Society of Electrical Engineers, November 12, 1894.

Digitized by Google

in several installations here, notably the Town Hall, Royal Exchange, Free Trade Hall, and Reference Library, and the advantage both to the contractor and the consumer is considerable. In the case of the contractor it saves labour, and in the case of the consumer current. There are also many installations wired either on the three-wire system or on a modification of it, which are very satisfactory and show a considerable saving in copper. I am inclined to think, however, that in the majority of provincial towns the most improved system of wiring is not recognised. As an instance, I may state from statistics that over 50 per cent. of the installations in Manchester are wired upon the now almost obsolete "Tree system." That is, a pair of mains are run throughout the building and lights tapped on indiscriminately as they are required, without regard either to the carrying capacity of the leads or the proper protection of the branches by cut-outs. I have come across cases, for instance, where a branch of 18-gauge wire, to carry three lights, was tapped directly on to a pair of 20's. No doubt the second wireman who was instructed to put on the extra lights was conscientious to a certain extent, but not sufficiently so to pull out the existing tapping and run his 18's direct to the main.

Such proceedings as this do not conduce to the satisfactory adoption of the electric light by the general public, who—and this is a fact we should never lose sight of—are to a great extent ignorant of technical details, and are in the majority of cases entirely in the hands of their contractors. In my opinion the most satisfactory way of wiring is that which now commonly obtains in London, and has also been adopted by a few provincial contractors—namely, the distribution system—confining oneself as far as possible to five-ampere sub-circuits, each controlled by a double-pole fuse. The advantage of this to the consumer is considerable, as it allows extra lights to be attached without much extra cost, providing, of course, that the contractor has allowed for this in his mains. Unfortunately, however, it is hard to explain to the prospective consumer that the small additional cost at the outset will probably be of advantage to him later, for a large proportion of the British public are inclined to accept the lowest tender, their object being to put in the light for the present without regard to the future. As to prices at which work is obtained, it would, of course, be invidious on my part to mention any figures, but when one sees, as I have done, variations of as much as 300 per cent. in tenders to specification, one cannot help feeling that there is something wrong somewhere. Of course it may be argued that certain contractors can buy material in a cheaper market than others, but I fear that this is not altogether a satisfactory explanation. One is rather led to the opinion that perhaps low quotations are a bait to catch work by contractors who are not already sufficiently established. There is at present going on in our papers a discussion as to whether certain manufacturers should be contractors. I think with regard to cable manufacturers, that perhaps it is somewhat unfair for them to compete with their clients, as friction is sure to be caused by such a proceeding. The manufacturers of fittings perhaps come under a different aspect, as a contractor is frequently asked for a special design or form of fitting, which, if he is himself a manufacturer, he can supply at short notice and comparatively moderate cost, whereas if he has to go to an outside firm, unless he is in a position to order a quantity, such firm will naturally charge him a high price, and the delay in delivery may be considerable. As far as regards cables and wire, the quality is fixed, and one is obliged to employ the particular form and size which is required.

The employment of efficient labour is of very great importance, and this brings me to the second essential. I may say that I have had a large and varied experience of the so-called wireman, and a very interesting and curious study I have found him. I suppose there are black sheep in every fold, but I am sure that the wireman's fold is particularly well supplied with the article. One finds among them individuals who seem to be given up to almost every form of vice from which they should be free. It is evident that the employment of these specimens of humanity is sure to result in trouble, yet sometimes the unfortunate contractor has no alternative. In the busy season one is often only too glad to get hold of a man who knows the difference between a double pole cut-out and a main switch, and your average wireman lets you know that he recognises this by demanding high wages or assuming an independent attitude. Perhaps I may be pardoned for suggesting that a paper on the subject of improving the condition of the electrical labour market would be of great interest, at any rate to a majority of our members.

I will now pass on to the third essential, the use of good material, and I fear that in these days of cheap continental rubbish this important point is often neglected. There are at the present time continental firms who may be said to run English contractors—that is to say, they get hold of a contractor who is short of capital and finance him by supplying him with inferior material, mainly fittings, at a low price. It is a matter for regret that such practices obtain, but I suppose they cannot be improved except by strict supervision on the part of the supply companies' installation inspector, and even then only to a limited extent, as there are loopholes in clients who instal their own plant, and who are thus independent of this source of criticism. Fittings are a very important factor in keeping up the quality of an installation and one which I fear many supply inspectors neglect. Often the inspector places too much confidence in his insulation test, or in the quality of the insulating material of wires and cables without stopping to see if lamp-holders or switches are defective, or proper cut-outs put in where they should be. Either of these points if neglected is a source of great annoyance, or may be danger, to the consumer, and allow inferior contractors to obtain jobs at low prices.

Then again, as I have before mentioned, prospective consumers often make a great mistake in accepting a very low tender on the supposition that it is economical to save a few pounds at first. The remedy for this lies in the employment of a consulting engineer. But I fear that even consulting engineers are not altogether free from partiality. When one sees in a specification, for instance, a certain make of switch mentioned one cannot get away from the feeling that perhaps there is more in it than the mere fact that the particular make of switch is efficient. However, consulting engineers have a great power in controlling the abuses of the trade, and one which I am sure we should all be glad to see more universally used. I fear that perhaps I have dwelt at too great length on some points which may seem trivial, while only briefly touching upon others which have an important significance, but if it should be thought that any portion of my paper is worthy of discussion I feel sure that many of our members would take a lively interest in it, and probably do more justice to this very interesting subject than I have done.

NOTES ON ELECTRIC TRAMWAYS IN THE UNITED STATES AND CANADA.*

BY H. D. WILKINSON, MEMBER.

In the paper communicated to this Institution, I have endeavoured to lay before you some notes on the working of electric tramways on the continent of America. I have not gone so much into descriptions of material and plant as into those questions which I heard constantly being discussed with reference to the return circuit of electric tramway systems, and the marked electrolytic action in some cities on underground pipes and cables. While the single-trolley system is almost entirely universal, I took pains to find out such details of the double-trolley system in Cincinnati, and the underground conduit in Chicago and Washington, as I judged would interest the members of this Institution, not only on account of their using an insulated return, but also on account of possible practical utility in their mode of working. For the details of these systems I must refer you to the original paper; but in order that the points put forward on the various systems may be made clear, I have had some diagrams prepared which show the general scheme of each. Considering first the predominating single-trolley overhead system—the mileage of which to-day in the United States and Canada exceeds that of all the steam, cable, and horse traction systems put together by 50 per cent., and to which, owing to its exceedingly adaptable and flexible character, the enormous development of electric traction in those countries has been due—we have the current supplied to the cars through the medium of a bare copper wire stretched centrally over the rails of the track at a height of about 19ft. from the ground. The current is collected from this wire by means of a thin steel tube and trolley wheel mounted on the roof of the car, the wheel running on the under side of the wire, and being kept up to the same by springs on the tube. The current is conveyed by an insulated wire to the controlling and reversing switches and fuse to the motors, a lightning arrester also being in circuit. The overhead trolley wire is divided into sections of one-quarter or half a mile in length, insulated from each other, and supplied with current from the power station by separate insulated feeders. As each section is independently supplied, it follows that the size of the trolley wire does not depend on the length of line, but simply on the length and average load per section, and is therefore uniform in size throughout, and generally about ⅓in. in diameter. On this system the current passes from the electric motors to the iron frame of the car, and thence by the wheels to the rails and earth. As the earth presents an almost infinite mass compared with the rails, it was assumed in the first instance that a return of least resistance would be secured by well earthing the negative poles of the dynamos. The coal bill, however, stimulated enquiry into the losses in transmission of electric energy. On many lines of five to ten miles the voltage at the most distant section between trolley wire and rails was only 50 per cent. of that generated at the station.

* Supplementary paper read before the Institution of Electrical Engineers, November 8, 1894.

Digitized by Google

Some improvement was made by sinking deeper earths into moist soil and connecting the same to more points on the rails. But at the best this was unreliable and variable, and it was noticed that improvement was more marked when attention was turned to the rails themselves as the best return conductor. High-resistance fishplate joints were bridged over by iron and then by copper wires, and the rails at their nearest point of approach to the power station were connected by overhead return cables to the dynamos, thus affording a reliable metallic return, while at the same time the earth formed part of the circuit. The first stage—namely, that described—is bonded rails and return cables.

In the second stage we have the rails connected at intervals to water and gas pipes; this step creating, from the traction companies' point of view, a most satisfactory rise of potential on the line, and improvement in speed of cars at the distant points on their system, but also raising the potential of the pipes above that of the earth, and bringing into existence electrolytic pitting and corrosion, followed by leakage and danger, and producing, as the secretary of the gas company in Washington described to me, a feeling akin to sitting on the top of a volcano. The electrolytic consequences ensuing on this method of "helping out" the return circuit led to a reconsideration of the matter. It was found impracticable to root out all such connections, or to provide such inspection as should prevent its recurrence, but the action was mitigated by clamping copper bands round the pipes at affected points, the same being connected to cables leading directly to the negative collecting bars in the power station. All this pointed to the advantage of a metallic return, and led to the use of a supplementary wire. This consisted of a bare copper rod, wire, or cable laid on the sleepers between the rails throughout their entire length, connected by twisted and soldered wires to the rails on each side of the fishplates, and cross-connected to a similar wire in the adjoining track every 30 yards. But on all lines which I have seen being laid in this manner the wires have been uniform in section throughout (about $\frac{3}{8}$in. diameter for the central wire, with smaller wires to bridge the rail joints), instead of increasing in section as they approach the power station in proportion to the increased volume of current. Unless proportioned to admit of constant density of current, I fail to see that this attains the desired end. The appreciation of this fact led to the adoption in Cleveland by Mr. Charles W. Wason of return feeders connected to the rails every 500ft. The feeders were increased in section and number as the lines neared the generating station, and added to from time to time to meet increased traffic. Other engineers whom I met were considering the adoption of such return feeders on their lines as a means of improving their efficiency of transmission.

Through all the stages thus far the idea has been retained that the negative poles of the dynamos must be connected directly to earth at the power station. Doubtless, if there are no return feeders and poor rail bonds, or if the return feeders are of insufficient section to carry the current ousted from rails so bonded, a portion of the current will take to the earth and metallic bodies within it on its way back to the generators; but, although it will cost a little more, I think we can afford to dispense entirely with the alternative earth path, and should do without it. The safety of buried pipes and cables would thus be assured, and the efficiency of transmission increased. It may be urged that the rails are perforce in contact with earth, and therefore the alternative earth path is always present. The answer to that is, let the negative poles of the dynamos be connected to the rails direct by insulated cables, but not to earth at the station, and the current will then be kept within the rails and return feeders. The only chance for current to pass to earth would be as a shunt round bond joints of high resistance or insufficient conductivity; and should this occur, it will only cause electrolytic corrosion at such joints, and not on underground pipes and cables.

Having arrived at this point, I now divide the exclusively metallic return so obtained under two heads—viz., feeders and rails. If we put return feeders to every half mile of rails, as we put them to every half-mile section of trolley wire, the bonds become of lesser importance—that is, firstly, they need only be of section sufficient to take the maximum current per section; and, secondly, they will be of uniform sectional area throughout. All the return current is then collected by the feeders and returned to the generators direct. Each feeder collects or drains off the return current for a certain distance on each side of its point of attachment to the rails, and when current is collected in this manner at several centres along the route, it cannot all rush to one spot, near the power station, where the density is not only seriously increased, but voltage and power are wasted. But if we do without return feeders altogether, then the current is returned entirely by the rails, and the bonds are of great importance. Since the original paper was communicated, rail bonding has been much improved, and I believe we can thoroughly rely upon these joints as permanent connections. Adequate area of contact with the rail, and that of a permanent character, are the main points. I have taken exception to the supplementary wire; but if increased in section, say, every quarter of a mile, as it approaches the power station, it would do nearly as well as insulated feeders, provided the connections from the rails to the generators were made at the nearest point to the power station by insulated cables. On lines where the route rounded curves or loops it would not do as well, because the current might find a short cut across corners if the earth favoured. By this method, also, current would be "bunched" at one point, instead of being collected and returned at intervals by feeders.

I now come to the double-trolley overhead system. In the original paper I have given an account of my visit to Cincinnati, Ohio, where this system is in operation. I went there to look into the system with an open mind and ascertain whether there were any adequate advantages to be gained for the use on one track of two overhead wires and two trolleys instead of one. The idea and the principle were, of course, complete insulation from earth. I need not repeat here what I have already reported as having seen in Cincinnati, but I may summarise by saying that I found one of the trolley wires in connection with earth, although not in direct connection. I could light the lamps in a single-trolley car by changing the trolley wheel on to one of the double-trolley wires which ran over the same track. However, no direct path for the return current through the earth would be offered by one wire being earthed, because there was (as there must be with this system) a complete return circuit of insulated feeders from the sections of negative trolley wire to the generators in a similar manner to that on the positive side. In other words, the return circuit was a complete duplication of the outgoing circuit, and the dynamos delivered their current outwards by insulated feeders, and received it back by insulated feeders of equal capacity. Any connection of either trolley wire to earth, therefore, could not cause a flow of current directly from the rails to the generators, since the latter were not in connection with earth at the power station. That this fact was an advantage, in view of electrolytic troubles resulting from return currents through earth, I could not doubt; but, notwithstanding the mechanical and commercial success of the double trolley in this city, I could not but reflect that, if we are to have overhead wires at all, one is better than two, and there might be other ways of effecting the same object. This led me to look at the single-trolley system again, and to ask myself the question, "Would not the same immunity from return earth currents be secured if, instead of earthing the generators and favouring an earth path, the return current should be collected direct from the rails by insulated feeders in communication with the negative side of the generators?" I am convinced that it would, and that the gaining of such immunity by insulated return feeders, connected at half-mile intervals to the rails on a single-trolley system, quite compensates for the extra cost. Thus I am led back to the same conditions as in the fifth stage, and this conclusion strengthens the position of the single trolley, while, so far as any superior advantage is to be gained, it disposes of the double trolley. At the same time, I am bound to admit that notwithstanding the increased amount of overhead work, and the extra insulation required at points and crossings, no serious mechanical difficulty presents itself in the double trolley, and the Board of Affairs of that city have acknowledged its practicability and success in authorising considerable extensions. To the gentlemen connected with both systems in Cincinnati, who courteously gave me opportunities of making observations on any part of their systems, and whose names I have mentioned in the original paper, I expressed at the time, after visiting the power stations and travelling over 10 miles in double and single trolley cars in the city and suburbs, my gratification in finding the double trolley work so well; but a somewhat over-zealous though well-meaning reporter put as one of the head lines of an article on my enquiry into that system, that "London will copy." I should be very sorry to disappoint that gentleman or his readers in their good wishes for our metropolis, but I have advanced points whick I think show that simpler systems can be made equally advantageous.

In the three-wire system two 500-volt generators are connected in series, the middle wire being to earth and the free positive and negative terminals connected to the feeders radiating from the station. The single overhead trolley wire is used, divided, as usual, into sections insulated from one another, so that the outside line work is precisely the same as in the two-wire system. Instead, however, of these sections being all of positive potential, they are connected alternately to the positive and negative feeders. Thus only a small part of the total current used in propelling the cars returns by the rails or earth to the station, and that only when the load is not balanced on the different sections of opposite potential. For this reason, I heard that the system was to be tried in districts affected by pipe corrosion on some of the great lines in Massachusetts, but with what result I have not heard. There is, however, a line in successful operation at Portland, Oregon, which I have not seen; but am pleased to say that the authors of the next paper, Mr. R. W. Blackwell and Mr. Philip Dawson, can give us details of the practical working of this system, gathered on the spot. I have also laid before

Digitized by Google

you some notes on the conduit or slotted-rail system, which has been working successfully for some time in Chicago and Washington, D.C., as I judged that the members of this Institution should be put in possession of such information as could be obtained on the spot. To avoid repetition, I must refer you to the original paper for details of this system. In the conduit there are two rigid copper rods supported from above at intervals on insulating blocks and gunmetal clips. The rods were in the first instance stretched continuously, but were afterwards divided into sections, with sleeves and springs to take up for expansion. I went up and down the line on the cars, which worked smoothly and perfectly; and by entering a manhole got my head in the conduit, so that I could watch the running of the trolley wheels as the cars went by. The sparking was inappreciable, and the system worked perfectly. The mechanical details at points and curves were well worked out. I have seen other conduit systems on paper, and there are probably several that would work equally well if given so fair a trial as that in Washington; but I have not thought it worth while to bring any system before a body of practical men, capable of designing as good systems as any others at present on paper, without having seen it myself in actual successful work; and the system described has certainly gained public and administrative confidence, and I believe has sound commercial prospects of further expansion. I was very pleased to see Messrs. Siemens's defence of the Budapest conduit line, which is both exhaustive and timely. Somehow or other, an impression has prevailed that a 1¼in. slot is inseparable from an electric system; whereas the case at Budapest was that advantage was taken of the wheel flange slot already existing, and this was necessarily somewhat wide. There is no difficulty in making the slot ⅝in., and bedding the insulated wires of the collector in an ½in. steel carrier. The conduit and slot in the centre of the track, however, is the most satisfactory, as it is not subjected to any continuous wear from the travel of the cars. Of the two systems of electric street tramways, the single trolley is most suitable for outlying districts and the conduit for towns. Although necessarily moving slower in town streets on account of the traffic, and therefore not showing all their good points, it must not be overlooked that electric cars have tractive power to tackle ascents of 1 in 10; and the running expenses per car mile are cheaper than by horses. The approximate total cost of buildings, machinery, and rolling-stock is the same in both the trolley and conduit systems, and amounts to from £1,200 to £1,500 per motor car. The overhead work and poles with single trolley costs about £2,300 per mile of double track, including permanent way, and the conduit system about £4,000 per mile of single track. Cost of rolling-stock and permanent way would, of course, be materially reduced for smaller gauges than 4ft. 8½in. The feeders, both main and return, should be underground, at any rate within town limits, after which there is not much objection to their being carried on the same poles as the trolley wire.

With the extensive experience gained in this country in underground conductors, a good drawing-in system, with spare ducts for adding to the feeders as traffic increased, could be laid in a thoroughly reliable manner, and not cost very much more than special overhead poles. We should then have the overhead trolley system without the great mass of heavy insulated feeder cables on tall poles so disfiguring in American cities. Let us bury our feeder cables and put up no span wires, and then all that is left is a set of light ornamental poles spaced 100ft. apart, with brackets supporting one single-trolley wire per track. Make them of lattice or ornamental scroll work, or make them of more massive ornamental cast iron, to receive, in addition, arc lamps for the lighting of the streets. But let us be assured that the overhead trolley is not so unsightly as many would have us imagine, and that it can be put up in an ornamental and unobtrusive manner. In Philadelphia the insulated feeders are in underground conduits, together with bare copper strips as returns, but I am not aware whether the dynamos are insulated at the power station, or insulated return cables led to the nearest point on the line in the manner I have described. The third-rail system is not generally applicable to any lines, except where built in an exclusive route of its own. The use of storage batteries I have not touched upon. There have been trials in America, but less experience gained than in England and the Continent. If the cost of depreciation and renewal, which is out of all proportion to that of the transmission systems, could be materially reduced, the self-contained battery system would claim attention for town and city traffic. Data on recently worked lines on this system would be welcomed from members who have had experience of such lines. American cars have no top seats, although the double-decked cars, as they are termed, are coming into use in a few places. We are lovers of fresh air, and except in the coldest weather in America, I have taken, in common with others of similar mind, the standing room on the driver's or conductor's platforms on American cars in preference to the inside. But we in England have somehow a strong inclination to get up higher, and we like to see around us from a position of vantage and freedom; and we cannot give up our top seats, no matter what other advantages are offered. Protection must therefore be afforded such passengers against any breakage of the trolley wire. Mr. Alfred Dickinson has met this in a very neat way, together with more important structural advantages, by putting his trolley wire on one side of the road. The matter could also be met by putting an awning over the top seats, as on the steam tramcars in Birmingham and elsewhere. With the conduit system, of course, top seats would need no such provision.

With regard to electric traction in the centre and outskirts of our own metropolis, while impossible in our already too crowded main thoroughfares, I am still of opinion that lines could be laid advantageously in our wider and less frequented thoroughfares, which would relieve the congestion of the narrower streets, and at the same time afford wide and attractive views, which would draw people by such a route by preference. For instance, let us say that one of our Westminster lights has been seeing a client in the City and is returning to Westminster—or perhaps it would be more dignified to say that a City client has an appointment with a Westminster luminary. He is, of course, pressed for time, and sooner than go by 'bus up crowded Fleet-street and the Strand, with an exasperating wait or change at Charing Cross, he will take a ticket at the Mansion House or Blackfriars and get himself put down at Westminster Bridge by the District Railway. But if someone informed him that electric cars ran every two minutes from Blackfriars to Westminster Bridge *vid* the Victoria Embankment, and would land him there in 10 minutes, I am very much mistaken if he would not take that route. At any rate, if nothing short of a cab would suit our City man on such a visit, I suspect that the route named would be much sought after and appreciated by the ordinary travelling public, and this noble thoroughfare would be made a scene of life and energy, and be an attraction to many who cannot spare the time to walk along it. I respectfully commend this to the notice of the London County Council as a scheme that might well be combined with that of the river frontage electric lighting, and be a work of great public utility. I only mention this in passing as an instance, but we have only to look around our outlying districts and see plenty of paying routes to our breathing spaces, open commons, parks, etc., where neither horses nor the railroad are practicable, where the ascents with heavy loads cannot be tackled by horseflesh, and railroads would mean cuttings and tunnels on the level; but the electric car can easily climb hills and take heavy loads of people to where they can get Nature's best tonics—long stretches of view and pure air. The termini of such lines could be situated with the greatest advantage at or near the suburban railway stations.

The points I have hitherto brought forward have been almost entirely confined to experience in the States, where, in fact, most experience has been gained; but in so far, at least, as administrative, industrial, and public opinion in this country may be influenced by what has been done on the New Continent, there is much to be said on the progress made by our compatriots in the Dominion of Canada. As in the States, the life is vigorous and expansive, but none the less in true accord with British instincts. The cities of Montreal and Toronto are well provided with electric tramways, and the citizens avail themselves of this means of transport in living out some distance in the suburbs. The streets of the city of Toronto are as well laid out and kept as those in our own metropolis, the roadways being asphalted, and the footways well flagged. The overhead trolley is everywhere in use and æsthetically does not intrude upon the general appearance of the city. In Montreal, I went over the new power station of the Montreal Street Railway Company, then being fitted up with engines and boilers of 3,600 h.p. The engines and dynamos were of Canadian manufacture, and the boilers were from England. This station was designed to meet the needs of the entire tramway system of the city after converting all the remaining horse cars into electric. The change meant an electric supply to something like 150 motor cars, with nearly as many trailers. The rails in these two cities are of the grooved girder type, imported from Great Britain, 72lb. to the yard, and laid, as in this country, directly on the concrete foundation of the roadway with tie-rods, but not sleepers. While scarcely coming under the head of ordinary road tramways, the electric line from Queenstown to Chippewa, Ontario, is of special interest. The line follows the western side of the Niagara Strait, near enough to the edge of the cliff to obtain magnificent views of the Falls and rapids, and was built by the Niagara Falls Park and River Railway Company on Government ground, rented at £2,000 per annum, with the object of developing tourist and excursion traffic. It was only opened in May, 1893, and in that summer 10,000 to 15,000 people travelled on the line per day, at fares ranging from 2½d. to 3s. The latter is the return fare covering 23 miles. The takings during July and August were £500 per day. Land in the vicinity fetched £40 an acre when the line was first constructed. After six months' working it fetched £100 per acre, and no doubt will continue to rise, as the company intend laying out a few good hotels, and the facility of locomotion promises the starting of good residential property on the heights, which have hitherto been unapproachable, except at rates particularly

Digitized by Google

gratifying to cabmen. The line is of the most substantial character, laid as a steam railroad, with 56lb. rails, on sleepers, and ballasted. There were last year 24 motor cars, 10 of which were "observation cars," and 18 trailers. The observation cars weigh 20 tons loaded, and carry over 100 people easily. They are specially constructed with two rows of seats, fitted lengthways in the car, one above the other, and facing one way, so that everyone can get the view. The usual thing is to run one motor car and one trailer with over 150 people aboard. It was anticipated that there would be a fair amount of traffic in winter as soon as the ice bridge was formed below the Falls, as this is a great attraction. There was a foot of snow on the ground when I went over the line, but the travelling was most agreeable, as the cars were kept up to a comfortable temperature by electric heaters under the seats, supplied with current tapped off the circuit. Six of these heaters in a car, three on each side in multiple series, consumed two amperes at 500 volts, and would therefore cost less than 3d. an hour. The cars were well lighted by incandescent lamps, and the route was lighted by clusters of these lamps placed at the top of every alternate pole. I am much indebted to Mr. W. T. Jennings, C.E., of Toronto, who designed the line and power plant, for his courtesy in showing me over the line and affording me information for this paper. The power is derived mainly from the Falls, a head of 57ft. clear fall being utilised, which now supplies three wheels of 1,000 h.p. each, one being in reserve. To meet the heavy loads when climbing the Queenstown heights, up a grade of 1 in 20, it was found more economical to put a small additional power-house down at that terminus, with dynamos driven by steam power, than run two 37/15 or one 37/12 insulated feeders from the water-power station, a distance of nine miles, which would have cost at least £2,600. This fact is significant of economies to be effected in transmission, and seems, as far as long lines and heavy traffic are concerned, to point to a practical conclusion as regards the maximum power per station in street tramway power plant similar to that enunciated by Mr. Crompton with reference to electric lighting stations—namely, that there is a limit to the amount of power it is economical to supply from one point only. The cost of insulated feeders comes in as a considerable item in first cost on lengths above five miles, and the loss of voltage and energy in transmission of the current is a continuous one. I think it worth while to consider high-tension transmission by underground feeders and the use of motor transformers, or the direct use on ordinary lines of what the Americans call "boosters," or motor generators; or, again, the three-wire system, or the establishment of power stations situated, not as they are now—namely, in the centre, from which lines radiate outwards—but at the most distant points, and feeding towards a centre. The stations are situated in this manner in the city of Cleveland, Ohio, and through the courtesy of Mr. Wason I am pleased to be able to show you a day-load curve. The largest curve, which reaches 3,400 amperes at seven o'clock in the morning, is from the original station, and the curves below are of two new stations feeding into the same network, and which together add another 2,400 amperes at the same hour. The curve was that for the day previous to my visit, when the ground was covered with frozen snow and the temperature was 9deg. of frost. Of the total current, about 600 amperes is used to drive motors in shops and factories.

I have specially made mention of the Canadian line at the Falls on account of four points which are deserving of notice and reflection. The first I have already touched upon—namely, the cultivation of tourist and excursion traffic along a route where attractive views and fresh air can be obtained. The second point is that the termini are in close proximity to two main lines of railway—namely, the Michigan Central and the Grand Trunk—which not only increases the tourist traffic, but creates a traffic of its own independent of scenery, but with the scenery thrown in. The third point is that the line passes near an agricultural and fruit-growing district, and special freight cars have been added for conveyance of these crops to the railways at rates lower than could formerly be obtained, and at the same time profitable to the tramway company. And, fourthly, the line forms part of a through connection between the two large cities of Toronto, on the north, and Buffalo, on the south, by steamboat connection at the termini of the line. The line has already been described to you by Mr. W. H. Preece, C.B., in his paper at the beginning of last session, in a more fascinating way than I can hope to bring it before you. When Mr. Preece first enlivened us by his presence at the Chicago Exposition, everyone who was bound to admit to him that he had not seen that line at the Falls felt somehow at once to have lost half his stature. Mr. Preece, like all Englishmen, when he takes his seat in a tramcar or railway carriage, likes to go ahead, and I do not think anyone could have put a more worrying enquiry to Mr. Preece than to ask him if he was going back to his hotel in Twenty-second-street by the elevated, or so-called rapid-transit, line. I suppose our suburban railways in the Metropolis, which I hold are second to none in the world for speed and safety, somewhat spoil an Englishman for any more tardy lines. While it is evident that the combination of fortuitous conditions in the Canadian Falls line is very exceptional, yet I am of opinion that, by keeping these and other favourable conditions in view, there are many districts in our own country where electric tram lines could be put down at once with advantage. I have drawn attention in my paper to some points in power-station plant, more particularly with reference to flywheel strains under the exceptionally sudden changes of load in street tramway work, which are sometimes the cause of serious mishaps. The ordinary fluctuations in load are caused by the starting or stopping by chance of a number of cars at the same instant, the variations being at times from over full load to quarter load; and the more excessive fluctuations are due to short-circuits, or the sudden release of load by automatic circuit-breakers. In one large station of 4,000 h.p., I was informed that the average was 20 short-circuits per day. Most of these were temporary, and caused either by high winds shifting some of the overhead gear, or falling telegraph or telephone wires, but in exceptional cases caused by the trolley wire itself breaking and falling on to the rails or ground. An overload or short-circuit, when driving by belt, puts a sudden brake on the periphery of the flywheel and a shearing strain on the spokes. The belt, of course, slips, but at times it parts or is thrown off, and in the course of its career sometimes damages the governor and leaves the engine uncontrolled, under which circumstances it is rare if there is time to shut down before something goes; and, as they tersely put it on the other side, it is best to get behind a pillar and await developments. The bending strains set up in the rim by centrifugal force in a racing engine appear to have been the cause of more fractures of the wheel than the shearing strains. The reason for wheels with one to two thousand foot-tons of stored energy is, presumably, to secure regulation of speed in engines having a small number of steam admissions per unit of time; but I think it will be admitted that the governor has more chance of producing an immediate effect upon the speed when there are a large number of admissions per unit of time, and there is the additional advantage in the use of much smaller and solid flywheels of approximately one-tenth the stored energy, and therefore well able to "stand the racket" with safety.

Regarding the use of belts, I think engineers in the States are coming to see that it is worth while to put a little more material in the generators, and do without these weak links in the chain of transmission. At any rate, I noticed many of the newer plants were direct driven, with marine-type engines. I admit that there is something very stately and imposing in a long row of trip-gear engines with large flywheels and belts. I enter very keenly into the enjoyment of such a sight, and am also much impressed by the number of yards super in stone and brick outside the building, and feet super of floor inside; but when we have to consider capital cost of works, and adaptability of plant to get down in good shape to its work under trying conditions with safety, we may wisely let such considerations take a secondary place.

Our corporations would do well to study the needs of the people in and around their townships; and I am confident that the good sense and judgment they, as business men, always display in schemes for the benefit of their townspeople, would lead them to select paying routes for light railways not paralleling the ordinary railways, and which would not only meet the needs of the daily transference of the population, but take in and out light market freights, and, by affording healthy travel, tend to foster the energies of their townspeople. The success of the Isle of Man electric tramway is an indication that such needs of the population do exist, and when catered for and fostered result in benefit to themselves, the promoters, and indirectly to the country at large. As I have before pointed out, such lines create traffic of themselves, and raise the value of land and property in the vicinity. I venture to predict that if facilities for reasonably quick and cheap travel between the suburban districts of our large towns and outlying villages were afforded the masses, they would gladly avail themselves of them. Such facilities would afford them enjoyment of open space, pure air, and opportunities of observing life in different grooves to their own, on the one hand, and cheap carriage for market produce, on the other, which could only have a beneficial effect, and would most probably bring about an alleviation of agricultural discontent, and a mitigation of the crises resulting from the labour problems of the day. Speeds can be accelerated somewhat in the open country.

The recent proposal made by the Board of Trade to the Chambers of Commerce and other bodies interested to discuss the question of light railways, is an action of much importance to the country at large, apart from the consideration of systems of travel, and one that I am sure is fully appreciated by this Institution. The questions of land, permanent way, signals, staff, level crossings, and fencing in where it is not practicable for such lines to take the high road are to be brought forward. The Board of Trade has ever shown the most ready spirit to favour electrical enterprises in the best interests of the public, with due regard to the protection of property, as exemplified in

Digitized by Google

electric lighting orders and in the drawing up of the present practical code of regulations for electric railways; and I have no doubt that the question of operating light railways in suburban, interurban, and country districts by electricity will be thoroughly brought forward by the Engineering and Electrical Trades Section of the London Chamber of Commerce, in response to the esteemed invitation issued by Sir Courtenay Boyle. We can count on our fingers the number of electrically-worked roads in the United Kingdom, and they can only claim a short mileage; but I beg to assure our American cousins that this is not because we are afraid of running into the sea. There are more people to the square mile in our large towns and cities than in more roomy America, and our streets are not mapped out on squared paper before a town is built. Hence the special character that must necessarily pervade our designs in electric roads. After all, mileage is not the only gauge of advancement. What will do for one American city, generally speaking, does for a second, a third, and a thousand. It is refreshing to notice the individual character in institutions, public works, and speech that obtains in the different townships of our country in contrast to the sameness of cities in the States. At the same time, this means more investigation into the needs of the people and design of road, calling for greater achievements, although not on so large a scale. Taking the cities of Liverpool and London, for instance, we have our elevated electric road, our subterranean electric road, and a second now building, which are engineering works of the highest order, and exceedingly well adapted to the necessities of our traffic. I call these achievements to be proud of.

In conclusion, I may be permitted to say that, while judging such information as I could bring to bear upon the question as it affects us in this country to be of interest to our engineers, as it certainly has been given me with infinite open-handedness and cordiality by my American friends, I do not cease to recognise the great labours and genius of our great engineers and electricians who have frequently addressed you in this room, and from the presidential chair in both this Institution and the Institution of Civil Engineers, and whose indomitable perseverance and energy have led the van in laying the earliest electric rails in the United Kingdom.

WORTHING AND THE ELECTRIC LIGHT.

A report has been submitted by Prof. A. B. W. Kennedy to the Worthing Town Council with respect to the proposed electric lighting of the town. He points out that it is necessary to give four schedules: the first setting forth the area within which the order is to apply; the second giving the list of streets through which the Council undertake to lay distributing mains within a period of two years after date of the order; the third giving a list of streets not repairable by the local authority, etc.; and the fourth dealing with the maximum price to be charged for electric energy under the order. The report proceeds: "As to the first schedule, you will no doubt take the whole area of the borough as the area over which you are to have the power of supply. As to the second schedule, I should advise, after full discussion with your Electric Lighting Committee, and after careful personal examination of your town, that it consist of the following streets and places: Marine-parade (from Warwick-buildings to Heene-road), South-street, Warwick-street, Chapel-road (up to the railway station), Shelley-road, Montague-street, Steyne." Explaining the schedules, the professor says the Corporation will undertake to lay distributing mains in the second schedule within two years. He thinks the Schedule II. area will increase rapidly. The professor advises the following maximum charges per quarter: for any amount up to 20 units, 15s.; for each unit over 20, 9d. The total length of roadwork in the compulsory area is 4·8 miles, to which has to be added about half a mile more in order to carry the mains into the station. In addition to this work about one mile of special pipes would have to be laid on the south side of the Marine-parade, to carry current for the arc lamps there, as these lamps ought no doubt to be rather placed beside the sea-walk than on the pavement nearer the houses. The 2,700 yards of frontage for shops included in the compulsory area covers all the principal shops in Worthing. Outside the compulsory area, therefore, nearly the whole of the extensions will be in residential streets. Altogether, the professor thinks that there are about 14 miles of frontage in which it may reasonably be expected that within a few years it would be advisable for the Council to lay down electric mains. All the shops in the compulsory area, if lighted by electricity in only a very modest manner, without allowing for arc or any other lights specially used in shops for advertising purposes, would probably take the equivalent of 7,500 lamps of 8 c.p. Of these he thinks it would be advisable to provide, in the first instance, for, say, two-fifths, or 3,000 lights. This is an estimate which does not make any allowance for the Pier Company as a possible consumer. The private houses in the compulsory area, again, on the assumption of each taking only a modest amount of electric light, would require the equivalent of 9,600 lamps of 8 c.p. In the first instance, the Council ought to provide for one-fourth of these, or 2,400 lamps. Altogether, they should not provide for less than the equivalent of 5,400 lamps installed, of which, in this particular case, about 3,000 might be alight at once as a maximum. For supplying the 3,000 lamps at one time—as well as the arc lamps with which he had to deal further on—Prof. Kennedy states that about 225 h.p. would be required, and in order that there may be proper reserve at the station, about 100 h.p. more than this must actually be put down. The report proceeds: "On the Marine-parade, where you of course wish to make a special show of light, it is advisable that arc lamps should not be placed further than 60 yards apart. This would require about 24 arc lamps. If lamps were placed at the same distance apart up South-street, and as far as the railway station, an additional 24 would be required, making 48 lamps in all. Very probably, however, from the sea-front to the station the lamps might be placed further apart, and so a smaller number might serve, but in the estimates which follow I have allowed for a total of 48 lamps. I have been informed that you are able to spare a part of the ground now occupied by the old waterworks as a site for an electric lighting station. I have carefully examined this site, and am glad to be able to say that it appears to be in every respect a most suitable one. It has ample area, it is fairly centrally situated, and it has the very great advantage that the steam-engines could be made to work with condensation, with a very small additional cost in plant, and with practically no additional cost for water. There is also a chimney stack about 70ft. high upon the ground, and this could be utilised quite well, at least for some time to come, for the purposes of the electric lighting station. I have no doubt also, from the appearance of the chimney and from what your borough surveyor has informed me, that it is strong enough to carry a considerable addition to its height when required. The old engines which are in the waterworks are, of course, of a type quite unsuitable for electric lighting. The boilers also are made for far too low a pressure to be economical. The highest pressure at which any of them can work is 60lb. per square inch, and it would not be economical for you to use a less pressure than 120lb. per square inch. In general, indeed, I find it advantageous to use a pressure considerably higher than this. I think, therefore, that you must consider that the waterworks site gives you simply the land, the chimney, and the possibility of condensation, but nothing in the way of plant. As to buildings, it would be very difficult to make the existing buildings—which have been specially schemed to suit the machinery which is in them—suitable for the purposes of an electric lighting station, and there would be no economy in attempting to do this. It would, no doubt, be advisable that special buildings should be erected on a part of the site at present unoccupied, where there is very ample area for this purpose."

Prof. Kennedy estimates the cost of the plant (for 3,000 8-c.p. lamps) at about £27,500. This includes the roadwork, plant, lamps, and meters. The sum of £3,500 is included for buildings. Should the scheme he recommends be carried out, an additional expenditure of £7,500 would increase the maximum output by more than 150 per cent. He proceeds: "With a view to estimating your probable income from the scheme, I have examined the figures for Bournemouth, Eastbourne, Brighton, and Hastings, as to the current sold per lamp wired. I find this varies from 13·5 units per lamp per annum in Bournemouth to 22 units per annum in Brighton. Taking the lowest figure—namely, that of Bournemouth—5,400 lamps would give you a consumption of 72,900 units per annum, or a total of £2,430 at 8d. per Board of Trade unit. I have already advised that you should ask permission from the Board of Trade to charge a maximum of 9d. per unit if necessary, but I have not thought it wise, in this estimate, to assume that you are actually charging more than 8d. . . . If you adopt the plan of having half the arc lights extinguished at 11 p.m, leaving the others to burn through the night, and charge for the lamps at the rate of £25 per annum for each lamp burning the whole of the night, and £12 for each lamp burning till 11 p.m., the total sum received for the lamps will very closely balance the total extra expenditure at the station on account of supplying them with current, including the cost of carbons, and including also the additional charges on the capital outlay. At the rates which I have just quoted the total expenditure in lighting the 48 arc lamps would be £888 per annum. I understand from the town clerk that the expenditure on gas and lamp cleaning along the same lines is at present about £340. The total cost will therefore be about two and a half times as great as at present, while the amount of light will be something like 40 times as great as at present. Adding the income from arc lighting at this rate to the income from incandescent lighting already estimated, it will be seen that the total amounts to £3,318 per annum, to which is to be further added, say, £150, for the rental of meters and transformers, making in all £3,468. I have given very careful attention to the question of the best system of supply to be used in your case. I find that Worthing differs from ordinary English commercial towns of about the same size, or larger, in that it has a very much smaller proportion of its streets taken up by shops, and a much larger proportion as private houses. In fact, out of the 14 miles of roadwork which you may very probably have to carry out within the next few years, practically only about 1½ miles—namely, the shop district comprised in your compulsory arer—is occupied by shops; all the rest is residential. Moreover, the larger number of the private houses are separate houses standing in their own gardens, and at a very considerable distance apart. These circumstances combine to make the length of mains which have to be laid unusually great in proportion to the number of lamps supplied. This makes the capital cost of a low-tension system of distribution, whether with low-tenson or high-tension feeders, proportionately great. For the sake, therefore, of the reduction of capital costs, I think that your system ought to be a high-tension one, with current supplied at

Digitized by Google

an electric pressure of 2,000 volts, transformed down to a pressure of 100 volts, as usual, before use in the premises of consumers. This system, as commonly carried out, has the very great drawback, especially for a town such as yours, that steam machinery has to be kept continuously running all night and throughout the daylight hours, although the actual paying load between each midnight and the following sunset is practically nil, and, as a consequence, the cost of coal per unit in such cases has been frequently most unreasonably large. The disadvantage can, however, be very greatly reduced by the use of a battery, and I consider that a battery of accumulators ought to be put down in your station with a motor alternator. In this way the battery would be charged in the evening, when the station was running at any rate, and would then discharge during the hours of light load through the motor, and thus drive a small alternator sufficiently large to supply current for all demands. In this way boilers and engines would be actually used only for seven or eight hours a day, as in a continuous-current (low-tension) station, and the running expenses both in coal and wages would be very much reduced as compared with a station in which steam has to be kept up all the 24 hours, and engines have also to be continuously at work. I have allowed for this in my estimate of costs both as to capital and revenue. For the arc lights the current would be supplied by the alternators in the station which supply the incandescent lamps, but I think that the current for the arcs ought to be passed through 'rectifiers' in the station, as is being done in Portsmouth, and as I am also arranging in Edinburgh. Lamps burning in this way appear in every respect more satisfactory than ordinary alternating-current lamps; indeed, in some respects they even have advantages over continuous-current lamps. I have allowed for this plant also in my estimate of costs."

LEGAL INTELLIGENCE.

CASSEL GOLD EXTRACTING COMPANY, LIMITED, v. THE ELECTRO-CYANIDE GOLD RECOVERY SYNDICATE.

The plaintiffs were registered owners of letters patent granted to several persons for improvements in obtaining gold and silver from ores and other compounds. The action was brought to restrain the defendant syndicate and two other defendants from infringing the patents. The counsel engaged for the plaintiffs were Sir Richard Webster, Q.C., Mr. Moulton, Q.C., Mr. Bousfield, Q.C., and Mr. A. J. Walter; and for the defendants Sir Edward Clarke, Q.C., Mr. Neville, Q.C., and Mr. T. M. Goodeve. **Mr. Justice Romer**, in giving judgment, said he was of opinion that the patent could not be sustained. The invention claimed was a very simple one, and the claim was very comprehensive, but no special apparatus, machinery, or device, or scheme of any kind was required to carry the patent into effect. Having regard to what was published and known at the date of the plaintiffs' patent, he came to the conclusion there was no real invention in the plaintiffs' alleged discovery. There was also another ground on which the patent was bad, because even if the invention was one which could be a good subject for a patent he thought it had been anticipated. The action would be dismissed, the plaintiffs paying the general costs. Execution would, however, be stayed pending an appeal.

WISE v. THE METROPOLITAN ELECTRIC SUPPLY COMPANY.

In this case the plaintiffs had in April last obtained an injunction against the company restraining them from carrying on their works at Manchester-street, W., so as to cause a nuisance to the plaintiffs by vibration. The operation of that injunction was, however, suspended until September 5. It will be remembered, says the *Times*, that the defendant company have established a large electric lighting station in the neighbourhood of Manchester-street, and the plaintiffs, who are householders and lodging-house keepers in the vicinity, complain of a nuisance caused by the vibration of the machinery. At the hearing of the action for an injunction it was proved that such vibration did exist to a serious extent. Owing to the peculiar nature of the soil upon which the works are erected, the task of preventing the vibration of the machinery from being communicated to the surrounding houses presents an engineering problem of great difficulty. At the time of the granting of the injunction the company were, under the advice of eminent engineers, endeavouring to overcome the difficulty by works intended to increase the rigidity of the bed or platform upon which the engines are rested, and although their operations in that direction were partially successful, they do not seem to have been entirely so, for the company have, since the injunction, come to the determination to substitute for the reciprocating engines hitherto in use steam-turbines, which, it appears, can be used without causing any vibration. The company have accordingly removed some of their old engines to another of their stations, and have already erected one turbine and ordered two others, which, when in position, will, it is hoped, enable them to supply all the necessary electric energy without using any of the old class of engines. In the meanwhile, the plaintiffs alleged that, in spite of the injunction, the company have allowed the nuisance to continue, and they now moved for leave to issue a writ of sequestration against the company. A great mass of evidence was read on either side, that of the plaintiffs tending to show that there had been very little, if any, abatement of the nuisance, and that of the company being to the effect that, since the granting of the injunction, there had been no such vibration caused by the engines as amounted to a breach of the order, and that they had almost, if not altogether, succeeded in overcoming the engineering difficulties. At the conclusion of the evidence his **Lordship** asked if the company were willing to undertake not to use more than one reciprocating engine, besides the turbines, for a period of three weeks, and, upon counsel for the company consenting to that, his Lordship said that it appeared to him, upon the evidence now presented to the Court, that if the company worked three engines of the reciprocating class a nuisance would be caused, but if they only used one there would be no such vibration as to amount to a breach of the injunction. He was anxious to be satisfied by a further experiment that that was so, and under these circumstances he should direct the motion to stand over for three weeks upon the above undertaking by the company.

The counsel appearing in the case were Mr. Hastings, Q.C., and Mr. Beaumont for the plaintiffs; Mr. Vernon Smith and Mr. Waggett for the company.

COMPANIES' MEETINGS.

WESTMINSTER ELECTRIC SUPPLY CORPORATION, LIMITED.

Lord Sheffield presided on Wednesday at an extraordinary meeting of the above Company, held at the offices, Eccleston-square, which was held for the purpose of confirming a resolution passed at a meeting on October 24 authorising an increase in the capital from £300,000 to £400,000. In formally moving the resolution, he said the Board had not yet arrived at a conclusion as to the price of issue and the date.

Mr. J. B. Martin seconded the motion.

Mr. D. Hutton considered that it would have been better if the shares were issued at par, and not at a premium, as was suggested, though he would not have objected so much if the Company had paid better dividends.

The **Chairman** stated that the course which the directors advised had been taken with the approval of their largest shareholders and financial advisers. He did not agree that the Company had not been successful, considering the great difficulties with which they had to contend.

The resolution was then carried.

WEST INDIA AND PANAMA TELEGRAPH COMPANY, LIMITED.

The ordinary general meeting of the shareholders of the above Company was held at Winchester House on Wednesday, Mr. C. W. Earle (chairman of the Company) presiding.

The **Chairman**, in moving the adoption of the report, said that during the past half-year, if they eliminated the results of a piece of luck they had met with about this part of last year, owing to an interruption in the working of the French cable, the normal traffic of the Company showed a decrease of about £2,400. One of the causes of these recurring decreases was that experience had enabled merchants by codification of messages to reduce the average number of words per message one-half since the Company had been at work in the West Indies. The other cause was the decline which had taken place in the price of sugar. The Company's earnings in messages to and from Dominica were so small that they sometimes amounted to £7 in a fortnight, while on one occasion no message was sent from the island and only one received. Still, the Company was compelled to maintain an establishment on that island, the result being that, as far as it was concerned, the Company, instead of being a commercial body, carrying on commercial business for itself, was in reality a company carrying on Imperial work for the defence and protection of the colony, without subsidy or assistance from the Imperial Government. With regard to the accounts submitted by the directors, there was an apparent—but more apparent than real—decrease in the expenditure to the amount of £300. This had arisen from the advantage given by an interruption to the work of the French cable. There was an increase in the cost of repairs and renewals attributable to the difficulty experienced in repairing the duplicated cable between Jamaica and Cuba, which had failed—the directors could not say from what precise cause—at 2,000 fathoms. The Danish colonies of St. Thomas and St. Croix had renewed their subsidies for five years.

Mr. W. Andrews seconded the motion, which was agreed to.

COMPANIES' REPORTS.

COUNTY OF LONDON AND BRUSH PROVINCIAL ELECTRIC LIGHTING COMPANY, LIMITED.

Directors: Right Hon. D. R. Plunket, Q.C., M.P., chairman; J. B. Braithwaite, jun., deputy chairman; W. C. Braithwaite; Anthony N. Denny; Frederick W. Reynolds; Aymor H. Sanderson; Francis E. Savory; R. Percy Sellon; B. H. Van Tromp. Engineer and manager: A. J. Lawson, M.I.E.E.

Report of the directors and balance-sheet to be presented to the

Digitized by Google

shareholders at the general meeting to be held at the City Terminus Hotel, Cannon-street, E.C., on November 19, 1894, at 2 p.m.

County of London.—The work necessary for giving effect to the provisional orders held by the Company for the districts within the county of London, is in active progress under the contracts mentioned in the prospectus of March 28, 1894, and by which it is provided that generating plant capable of supplying 90,000 8-c.p. incandescent lamps shall be erected by September 30, 1895. Contracts for the laying of pipes for street mains have been entered into, and are now being executed. It is intended to at once lay sufficient conductors to meet immediate requirements, together with a number of spare pipes into which, without further disturbance of the roadway, additional cables may be drawn when required. The directors have acquired at a moderate rental, under a 99 years' lease, a suitable site at the Regent's Canal Basin, upon which the generating station for the St. Luke's and Clerkenwell districts will be erected, and they have made arrangements with the owners for obtaining additional land, should it become necessary at any time to enlarge the buildings. The freehold has also been secured of riverside premises in the Wandsworth district, upon which the generating station for that area will be built. At both these stations coal can be delivered out of barges alongside the buildings, and there is an abundant supply of water available for boiler feeding and condensing purposes.

Provinces.—The Company has purchased a controlling interest in the Bournemouth and District Electric Supply Company, the extension of whose business during the past year has been very encouraging, and it is expected that the accounts for 1894 will show a substantial profit. The connections to the mains of the Bournemouth Company are now equivalent to about 18,000 8-c.p. lamps. The Company is also largely interested in the Dover Electricity Supply Company. Work upon the station buildings and mains of that company is approaching completion, and it is expected that it will be in a position to supply current to consumers by the end of the present year. The prospects of the Dover company are very hopeful in view of the arrangements already entered into with the Corporation for street-lighting and with the military authorities. Other important lighting contracts at Dover are also in course of negotiation, with every probability of a satisfactory conclusion. At Windermere the water power of the River Leven, at the outlet of Lake Windermere, has been secured, and the Windermere and District Electricity Supply Company has been formed for the purpose of utilising this power in supplying current at a moderate price to such towns in the neighbourhood as may desire to avail themselves of it.

Future Annual Accounts and General Meetings.—It is intended to close the financial year in future on December 31, and to present the accounts to that date at the annual general meeting to be held in March or April following. Under this arrangement the next general meeting will be held early in 1895, when the provisions contained in the articles of association with regard to the retirement and election of directors and auditors will take effect.

Balance-sheet to June 30, 1894.	£	s.	d.

Maschinenfabrik Oerlikon.—This Company inform us that at the International Exhibitions of Lyons and Antwerp this year they have obtained the highest award, the *grand prix*, for electrical machinery.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

York.—Tenders are invited by the directors of the North-Eastern Railway Company for telegraph apparatus and for telegraph wire and line stores. Forms of tender may be obtained on application to Mr. Graves, Telegraph Department, York, and tenders must be sent in to the secretary at York by Tuesday, 27th inst.

St. Pancras.—The St. Pancras Vestry invite tenders for works under the following two contracts: (*a*) supplying and laying armoured cable mains; (*b*) extension of underground sub-station building. The drawings can be inspected, and specifications, schedules of quantities, and general conditions can be obtained, at the offices of Prof. Henry Robinson, C.E., 13, Victoria-street, Westminster, on payment of 5s. for each contract. Tenders to be sent to Mr. Albert E. Pycraft, chief clerk, Electricity and Public Lighting Department, Vestry Hall, Pancras-road, London, N.W., on or before 22nd inst.

Derby.—Among stores for which the Midland Railway Company ask for tenders by the 20th inst. are (10) telegraph instruments, stay-rods, bolts, etc.; and (10a) telegraph and signal wires. Contractors cannot be allowed to submit or tender to supply goods to their own patterns, nor can the company's patterns be sent away for inspection, all being sealed, and exhibited at Derby only. The patterns are ready for inspection at the General Stores Department, Derby, and forms of tender may be had on application to Mr. G. Morrall, Derby, care being taken to give reference to the particular contract (by the above numbers) for which it is proposed to tender. Tenders to be addressed to the secretary.

Hampstead.—The Vestry of St. John, Hampstead, invite tenders for wiring the buildings in the stoneyard, Lithos-road, Finchley-road, N.W., for the electric light, including the supply and fixing of all cables, casings, and electrical fittings; but not lamps. A form of tender, with copy of specification and a description of the general routes to be followed, may be obtained at the office of the vestry clerk, Vestry Hall, Haverstock Hill, N.W., upon the deposit of £1. 1s., which will be returned on receipt of a *bonâ fide* tender. The various buildings at the stoneyard may be inspected on presentation of an order to do so, signed by the vestry clerk. Tenders must be delivered by Thursday 29th inst.

RESULTS OF TENDERS.

London, N.—The Vestry of St. Mary, Islington, have received the following tenders for the erection of the structural part of the new electric lighting station at Eden-grove, Holloway, N. Mr. A. Hessell Tiltman, 6, John-street, Bedford-row, W.C., is the architect, and the quantities have been got out by Messrs. Young and Brown, 7, Southampton-street, Bloomsbury, W.C.:

		A.
Rider and Son	£24,996	£1,800

A. Extra for glazed-brick facings.

BUSINESS NOTES.

Chester.—In taking office as mayor, Mr. W. H. Churton stated that he hoped to see the electric light question settled during his term of office.

Staverton.—The mills and stores of Mr. E. J. Bowden's Staverton Bridge Roller Mills have been lighted throughout by electricity.

Blackburn.—Mr. E. M. Lacey, C.E., Westminster, has been chosen by the Gas Committee of the Town Council as consulting electrical engineer to the Corporation.

Burton.—The new Town Hall, which has been presented to the town by Lord Burton, is lighted electrically, the work having been carried out by Messrs. B. Verity and Sons.

Walthamstow.—The Local Board have made application for a provisional order to enable them to produce and supply electric light for public and private purposes within the district.

Southampton.—Mr. Button, the newly-elected mayor, in his opening address has pointed out the advisability of the Town Council acquiring the works of the electric light company.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 11th inst. amounted to £892, as compared with £577 in the corresponding week of last year.

Carlisle.—The Town Council have approved of the minutes of the Gas Committee describing the preliminary steps which have been taken with reference to getting a provisional order to supply electric light.

Blackpool.—The Electric Lighting and Tramways Committee of the Corporation is now constituted as follows: Aldermen Bicker-

Digitized by Google

staffe and Buckley, Councillors Blundell, Heap, Hampson, Pearson, Smith, and Sergenson.

Hove.—Mr. F. G. Clark, auditor of the Hove Electric Lighting Company's accounts, has presented his report to the Town Commissioners on the statement of accounts to December 31 last.

Bath.—The Surveying Committee of the Town Council have decided that the electric light company should be paid £10 a month from the present time till February for an additional half hour's lighting in the morning.

Fareham.—The Local Government Board have informed the Local Board that with reference to the borrowing of £7 000 for the purchase of the electric lighting plant a public enquiry would be held as soon as business permitted.

Whitechapel.—The Board of Guardians have decided to fill in the forms sent round by the District Board in respect to electric lighting, but it was understood that this did not bind the Board to take the electric light for the workhouse and infirmary.

Worcester.—The Town Council have decided to arrange with the Brush Company to work the electric light installation for three months from October 11. The city engineer has been instructed to report on the work which has yet to be completed.

Wolverhampton.—The Lighting Committee of the Town Council have received 37 applications for a supply of electrical energy. These applications, including the lighting of the municipal buildings, represent a total of nearly 5,000 8-c.p. lamps.

Newport.—The Newport Town Council have discussed the question as to the probable cost (£600) of fitting the electric light at the Town Hall. It was decided to go on with the fitting of the Town Hall. Applications for the electric light are coming in rapidly.

Canterbury.—The members of the Electric Lighting Committee are the Mayor (Mr. George Collard), Aldermen Cross and Mount, and Councillors Mills, Mourilyan, and Warren (re-elected), with Councillor Lukey in place of Councillor Wiltshire, and Councillor Dean added.

Motherwell.—The Motherwell Police Commissioners have unanimously agreed to procure a provisional order empowering the Commissioners to introduce electric light, the subsequent action of the Commissioners in the matter being subject to review after the order is obtained. It is estimated that the total cost would be £12,500.

City and South London Railway.—The receipts of the Company for the week ended November 11 were £969, against £911 for the corresponding week of 1893, or an increase of £58. The total receipts for the current period of the present half-year amount to £16,719, as against £15,591 in the corresponding period of 1893, an increase of £1,128.

Dover.—It has been reported to the Town Council that a new contract with the gas company for lighting the borough would shortly have to be entered into, and it was decided to obtain prices for lighting the usual lamps, and a price for keeping up and clearing columns which would not be used owing to the proximity to the electric lamps.

Bristol.—The following have been appointed members of the Electric Lighting Committee of the Town Council: The Mayor (Mr. R. H. Symes), Aldermen Pethick and Proctor Baker; Councillors Tryon, Hughes, Lloyd, Board, Bastow, Hill, Wills, Pearson, and Pembery. The Docks Committee will light the new Dean's Marsh shed electrically.

Michael Corbitt and Sons, Limited.—This Company has been registered with a capital of £50,000 to acquire the business and assets of T. W. Spencer and Co., Limited, of Hebburn and elsewhere, and to carry on the business of hemp and wire rope manufacturers, telegraph, telephone, and electric light cable manufacturers, lightning conductor and electrical appliance manufacturers, etc.

Brighton.—The Lighting Committee of the Town Council have in a report recorded their high appreciation of the unremitting attention and zeal which Alderman Moon has devoted to the business of the committee, and the opinion that the success which has attended the electric light undertaking of the Corporation is in a great measure to be attributed to his earnest advocacy and great administrative ability.

Bournemouth.—The Town Council have accepted the offer of the Electric Supply Company to light the Winter Gardens for three or 5½ years, charging on the basis of their current price for the time being, less a discount of 25 per cent. The town clerk was instructed to prepare an agreement for 5½ years, to be determinable at the expiration of three years, at the option of the Council, on giving six months' previous notice.

Ormskirk.—Preparations are being made on a site in Southport-road, near to the parish church, for electric lighting works in accordance with plans submitted by a private firm of electrical engineers, and recently passed by the Local Board. It is intended to commence fixing the engine and dynamo in a temporary erection on the site of the building, and to proceed with the permanent structure at the same time, which, when completed, will be 190ft. long and 60ft. wide.

Poole.—The Town Clerk stated that he had received a letter from the Board of Trade with reference to the application of the promoters of the Poole and Bournemouth tramways asking for a further extension of time for the commencement and completion of the tramways, and under the circumstances the Board of Trade gave their sanction to the proposed extension till August, 1895. The town clerk added that the promoters had given the guarantee which the Council had asked for.

Bradford.—The new Gas and Electricity Supply Committee of the Town Council consists of the following gentlemen: Aldermen Edhouse, Feather, Lobley, Morley, Moulson, Watmough, and Whitley; and Messrs. Armitage, W. E. Aykroyd, Barker, G. A. Booth, Crossland, Dixon, Dobby, Dobson, Freeman, C. Greenwood, J. Greenwood, Hayhurst, Jennings, Kay, Land, North, Pilling, Popplewell, Ratcliffe, Speight, Toothill, Townend, and Walker.

Lynton.—The Local Board have received a letter from the electric lighting company stating that they would be glad to know whether the Board wished to have the lighting extended to the outer district. The Clerk to the Board (Mr. Roberts) said, at a recent meeting, he had written in reply that before a fresh agreement was entered upon it would be necessary that a test should be applied to ascertain whether the light already provided was in accordance with the present arrangement.

Telegraph and Telephone Appliances.—Messrs. F. Butzke and Co., Limited, manufacturers of telegraph, telephone apparatus, and accessories, of Berlin, inform us that they have appointed Mr. G. Straus, of 130, Queen Victoria-street, London, E.C., as their representative for Great Britain. The showrooms of Mr. Straus contain a complete set of samples of Messrs. Butzke's telephones, bells, speaking-tubes, fire and burglar alarms, and accessories, and an English catalogue will shortly be ready.

Swindon.—The Swindon Local Board recently discussed the subject of lighting the town by electricity. The General Purposes Committee recommended that Mr. J. G. W. Aldridge, of Victoria-street, Westminster, should be the electrical engineer for the purposes of the provisional order. It was further resolved that the notice applying for a provisional order should include every street within the district and all the public buildings belonging to the Board. The committee's recommendations were adopted.

Eccles.—The following members of the new Town Council have been chosen to constitute the Town Hall, Tramway, and Electric Lighting Committee: Aldermen Kendall and Mellor, Councillors Farrar, Hamilton, M.D., Heath, Oldfield, W. Smith, M D., and Whitehead. Alderman J. F. Wilkinson, on his appointment as mayor, stated that by a provisional order the Council had power to adopt a system of electric lighting, but the ratepayers might have every confidence that, whether that order was carried out or not, it would be proceeded with on careful lines.

Extension of Premises.—Mr. Robt. W. Paul, of 44, Hatton-garden, E.C., informs us that he has again been obliged to obtain more factory accommodation, and that he has taken the lease of Nos. 114 and 115, Great Saffron-hill, E C., a few doors from Farringdon-street Station. These premises have been equipped with new machinery and engine, and Mr. Paul has increased his staff with a view to manufacturing his high-class electrical and physical instruments in an expeditious and economical manner. He has also retained his premises in Hatton-garden for office purposes.

Keswick.—The Street Committee of the Local Board have received a letter from the Keswick Electric Lighting Company, Limited, giving notice of the company's intention to apply for a provisional order under the Electric Lighting Act, and asking if the Board would have objection to the company being released from supplying current continuously during the 24 hours, as required by the Board of Trade. The committee recommended the Board to acknowledge receipt, but to give no pledge as to the course of action they may adopt upon the letter. The report has been adopted.

Bacup.—The Liberal Club has been lighted by electricity. The installation has been put in by Messrs. Matthew and Yates, of Manchester, under the supervision of Mr. Thomas G Slater, the electrical engineer to the firm. Power is supplied by a "National" gas-engine of 8 h.p. nominal, running at 180 revolutions per minute, and driving a Matthew and Yates compound dynamo which, running at 1,200 revolutions, has an output of 80 amperes at 100 volts. The incandescent lamps amount to a total of 1,510 c.p. Five electric air-propellers are used for ventilating the card, committee, billiard, and lecture rooms.

Swan United Electric Light Company, Limited.—Shareholders of this Company are requested by the liquidator to send in their certificates in exchange for the new securities. Each holder of five fully-paid shares will receive in exchange as follows: 3¼ fully-paid £5 shares in the Edison and Swan United Electric Light Company, Limited, £6. 0s. 7d. debenture stock, £1. 0s. 8d. cash, being dividend and interest to June 30, 1894. Each holder of five partly-paid shares will receive as follows: 3¼ partly-paid £3 shares in the Edison and Swan United Electric Light Company, Limited, £4. 16s. 6d. debenture stock, and 14s. 2d. cash, being dividend and interest to June 30, 1894.

Extension Ladders and Fire Appliances.—An illustrated price-list of their specialities has reached us from Messrs. J. H. Heathman and Co., of 2 and 37, Endell-street, London, W.C. Attention is first directed to the fire appliances made by the company, and then to their variety of extension ladders, of which a large number is already in use. Other manufactures include bank trolleys, cask trucks, luggage bogies, barrows, hand-carts, etc. We note from the list that the company's fire appliances have been supplied, among others, to the Royal stables at Buckingham Palace, to Earl Malmesbury, and the Duke of Norfolk, to various theatres and music halls, public buildings, local boards, schools, etc.

West Bromwich.—The Corporation have been agitating for the South Staffordshire Tramway Company to adopt a better system of traction upon their lines running from Darlaston to Handsworth and from Dudley to Handsworth. The license for the use of steam expired on the 1st inst., and the Corporation thought

Digitized by Google

it time that the company should make some definite arrangement as to when a better system would be introduced. They have, however, consented to the license being extended until January, 1895, the company in the meantime to make some definite arrangement. The Corporation is said to favour cable traction. The company, however, favour the electric system, and point to its successful working on their other lines.

Hampstead.—The Metropolitan Asylums Board met on Saturday last, when they approved of the action of the North-Western Hospital Committee in having engaged Prof. Ayrton to prepare a report on the question of lighting the North-Western Hospital by electricity at a fee of 30 guineas, to prepare a specification for wiring the hospital at a fee of 20 guineas, and to supervise the work for 75 guineas, with an additional charge of three guineas for each attendance on the committee, and to accept the offer of the Hampstead Vestry to supply electrical energy to the North-Western Hospital at 4d. per Board of Trade unit, the agreement in the matter to last for three years certain. The committee will shortly advertise for tenders for wiring the hospital.

Heising's "Acid-Proof" Enamel."—We have received from Messrs. E. Wallace and Co., Limited, 30, Newgate-street, E.C., who represent Messrs. Heising and Co., of Berlin, particulars of Heising's "acid-proof" enamel, specially prepared for the electrical trade. It is stated that this enamel has been tested, and is recommended by Messrs. Siemens and Halske and the Accumulator Works at Hagen among others, and that it is the only absolutely reliable protection for accumulators and accumulator-rooms against the destruction of walls, ceilings, and woodwork by acid sprays, fumes, or gases. It serves for the protection of battery jars and all other electrical apparatus which are used in connection with acid. We are informed that it is also an excellent insulator for dynamos, cables, and wires.

Chiswick.—The Works Committee of the Local Board have reported with regard to the progress of the works at the electric lighting stations, and recommended that a letter be written to Messrs. Bourne and Grant expressing the Board's dissatisfaction at the slow progress of the work. The surveyor said that the work had been stopped because Messrs. Bourne and Grant wanted to excavate a larger area of land for the work than was stated in the agreement. They intimated that they were not aware there was any limit fixed to the area of land to be utilised, and the works could not be proceeded with in the area mentioned in the agreement. Captain Alleyne said the best method to adopt was to ask Messrs. Bourne and Grant to submit plans of the work showing the area of land required. This was agreed to.

Hertford.—After a long and heated discussion the Town Council on Friday last agreed to the following resolutions proposed by Alderman Willson: "That the following resolutions, passed at the meeting of the Council held on September 7, 1894, be and are hereby rescinded: 'That the electric lighting scheme prepared by the engineer, extended so as to supply the Hertford General Infirmary, be carried out as speedily as possible.' 'That the engineer be instructed, with the assistance of the borough surveyor, to prepare detailed plans for carrying out the scheme, and the requisite forms of tender for the several sections of the same.' 'That application be made to the Local Government Board for their sanction to the loan of £6,000 for the purpose of carrying out the scheme'"; and "That all orders and instructions given to give effect to these resolutions be forthwith cancelled."

Halifax.—Alderman Michael Booth, who has been elected mayor, on the occasion of his opening speech, stated that the time was fast approaching when many of the shops in the town would be lighted with electricity supplied by the Corporation. He did not know whether the Gas Committee had considered the feasibility of producing this light by other means than coal and coke, but he understood that at Ealing the electric light had been produced by the burning of the town refuse, and at Worcester by the utilisation of compensation and other waters by means of turbines, in each case effecting a great saving by dispensing with the use of coal. In the face of the rapid development of electricity for producing light, heat, and power, as well as for cooking and other purposes, any extension of the gasworks beyond what was absolutely necessary for immediate purposes would, he believed, be wisely suspended.

Llandudno.—A public meeting was held on Wednesday for the purpose of considering a scheme for the lighting of the town by electricity. The meeting was promoted by the Llandudno Electric Supply Company, Limited, and the chair was taken by Mr. R. Conway, C.C., and a number of the Town Commissioners was present. Dr. Nicol, J.P., chairman of the company, who was unable to be present, sent a letter to the chairman, in which he said that the light was desirable on the ground of health and cleanliness. It was desirable that local authorities should have control over the lighting of their districts, but in Llandudno that was not expedient, as the town was already burdened with a heavy debt, and there were in the future large schemes to be carried out which involved heavy outlay. A resolution put to the meeting expressing the opinion that the work of supplying the electric light should be undertaken by the company was lost.

Kingston (Surrey).—By the erection of electric arc lamps in the streets, the Town Council have reduced the gas lamps by 99 compared with last year. Councillor Collings has given the Council a few figures as to the development of the electric lighting business. In the first quarter—up to December 31, 1893—there were 2,050 lamps installed, the current used was 5,596 units, and the revenue received was £139. 18s. The next quarter up to March 31 showed an increase of 450 lamps, by the end of June there was a further increase of 550 lamps, by the end of September another 250 lamps had been installed, and up to that day (less than half a quarter) 264 extra lamps had been fixed. The total number of lamps now installed was 3,564, and up to September 30 the current supplied had reached 25,219 units, for which the money received was £630. 19s. 6d., with an additional £29. 3s. 6d. for meters. They would see that the business was rapidly increasing, and he hoped and believed it would go on until it was made a financial success.

Milngavie.—On Friday last, the electric light was introduced here. On the site of the old calico print works ex-Provost Woodburn has erected several tenements. The shops and houses along Station-road have been fitted up for this light. The power is obtained from a turbine, which is driven by water from the River Allander 100 yards away, and led to the turbine by a "trow" 4ft. by 3ft., partly concreted and partly of wood. Provost Drew turned on the light in the new hall, where Mr. Woodburn was surrounded by his brother commissioners and the chief residents of the place. The turbine was provided by Mr. MacDonald, of Pollokshaws, along with the main shafting. The electrical plant was supplied by Messrs R. D. Smillie and Co., and erected by them. The dynamo is capable of supplying 150 incandescent lamps of 16 c.p. Mr. Smillie, the engineer, stated that this was the first occasion in Scotland in which water power had been used to produce electric light for shops and dwelling-houses, and that it would be copied by others.

Paisley.—The Town Council have received a letter from Mr. Thomas Henderson, secretary of the Caledonian Electric Supply Company, Limited, intimating the intention of that company to make application for a provisional order authorising them to supply electricity within the burgh, and proposing to make offer for a transfer of the provisional order obtained by the Council. The minutes showed that Mr. Bryson, electrical engineer, Glasgow, had made a statement as to the prospects of electric lighting. He gave it as his opinion that it was not desirable for the Corporation to undertake the work, and that it would be preferable for them to transfer their provisional order if suitable terms could be arranged. After consideration, it had been agreed that the clerk should write to Mr. Henderson asking that his directors should make an offer for a transfer of the order, and Mr. Bryson also undertook to obtain an offer from the Scottish House-to House Supply Company, Limited. The minutes were adopted.

"Snowflake" Composition for Coating Lamp Bulbs.—Being in the neighbourhood of Regent's Park, one of our representatives called upon Mr. V. Fabris, electric light contractor, of 171, Drummond-street, Hampstead-road, N.W. The attention of our representative was particularly called to the "Snowflake" composition, prepared by Mr. Fabris, for coating the bulbs of incandescent lamps. This composition, which is porous, allows some of the direct rays from the filament to pass, which, in combination with the reflected light, has a very pleasing effect, and produces, it is claimed, a light of more equal intensity over a larger area than can be obtained by using ordinary incandescent lamps. Among other advantages claimed for this composition may be mentioned (1) that it can be permanently fixed on any portion of the globe, throwing the reflected rays in any direction; (2) that the light is of a pure white quality, thus reducing the yellowish tint produced in ordinary incandescent lamps; (3) that lamps coated with this composition dispense with the use of all other kinds of shades shells, or additional reflectors; and (4) that by using this composition the fixing of the bulb to the brass rim of the lamp is strengthened.

Acton.—A communication has been received by the Local Board from Messrs. New and Mayne, who stated that they had gone into the question of taking up the electric lighting of the district, and the result of their enquiries and investigations was that they were fully satisfied that the district was one that could be economically lighted by electricity. They offered to take over the Board's provisional order in the matter, and to put down the necessary plant. They understood that the principal object of the Board was the lighting of the public streets by electricity, and they had no doubt that they would be able to carry out that work at a lower cost than was incurred by gas-lighting. In further letters the company suggested that in connection with the proposed electric lighting works they might arrange to erect and run a dust destructor, and they asked the Board to transfer to them the monopoly of electric lighting for 42 years, instead of 21, as was proposed by the Board. A letter has also been received from Mr. Smith, making a proposal for the purchase of the electric lighting order. Both these letters have been considered by the Works Committee, and the committee reported that they considered that Messrs. New and Mayne's stipulation for a lease of 42 years was reasonable, but that they could not recommend the Board to sell their order for less than £500. The committee decided to take no action for the present regarding Mr. Smith's letter. They had ordered the clerk to prepare a draft agreement for the transfer of the order to Messrs. New and Mayne.

Western and Brazilian Telegraph Company.—The total earnings for the half-year amount to £77,603. 3s. 6d., as against £79 373. 10s. 4d., a decrease of £1,770. 6s. 10d. compared with the half-year to June 30, 1893. The working expenses amount to £39 739. 11s. 5d., as against £43,424. 1s. 3d, a decrease of £3 684 9s. 10d. Including the amount brought forward from 1893 (£1,045. 6s. 6d.), the balance to the credit of the revenue account is £38 908 18s 7d., from which has to be deducted £11 672. 10s. for debenture interest, £5,000 for the debenture redemption fund, and £2.000 placed to reserve fund This leaves £20,236 8s. 7d. The directors recommend the payment of a dividend, free of income tax, for the half-year at the rate of 2 per cent per annum, carrying forward £5,630. 6s. 7d. This

Digitized by Google

dividend will be payable as follows—viz., 3s. per share to the ordinary shares and 3s. per share to the preferred ordinary shares The conversion of ordinary shares into preferred ordinary and deferred ordinary shares will be suspended on and after January 1, 1895, until further notice. The Company have received from its representative in Rio de Janeiro the following communication: "Urgent.—Bill presented yesterday in Congress, and published to-day, November 8, in *Diario Official*, authorising the Government to purchase at once the Western and Brazilian Telegraph Company under conditions of Clause 14 Decree 5,270 of April 26, 1873, of the Western Company's concession, and to emit special telegraph bonds, value £100 sterling, bearing interest at 5 per cent. per annum, for this purpose." For the past week the receipts were £3,132.

Glasgow.—The arrangements for lighting the Corporation cars by electricity are now completed, and a few weeks probably will see the old oil lamps displaced by the new illuminant. The Froggart Electric Lighting Company, Limited, whose system is at present used in London, are the contractors, and Mr. Thomas Froggart, the patentee, is already at Coplawhill depôt carrying through the preparations for the change. In each car there are to be four lamps—two inside and two outside—and each is to be of 8 c.p. On the outside the lights are to be elevated on iron standards from 3ft. to 4ft. above the level of the roof, and each, in an elliptic glass globe with copper frame, will be in the centre of a disc of about a foot in diameter. On the one side bullseyes of particular colours will unmistakably indicate the routes, and on the other a white light will illuminate the top of the car sufficiently to enable passengers to scan their evening newspapers on their way home. The lamps in the inside are to be placed in the roof. In order to avoid vibration, the accumulators on all the Glasgow cars will be suspended on powerful indiarubber straps. Each lamp is also fed from a separate accumulator on the platform, so that in the remote contingency of one failing the car will not be left without a light. At Coplawhill and Kinning Park buildings are being erected for dynamos, charging gear, and so forth, and here the accumulators, which are to contain sufficient current for 10 hours, will be recharged, being conveyed afterwards to the different depôts in specially-constructed vans. The intention is, it may be pointed out, to utilise part of the disc for advertising purposes, with the object probably of as far as possible reducing the cost of the light. With the exception of a circle in the centre of from 4in. to 5in. in diameter, the disc will be devoted to an artistically coloured advertisement.

Leeds Tramways.—The City Council on Wednesday met to consider the question of making application for a provisional order for the extension of the tramways, and an adjourned meeting was also held to dispose of the business left over from Friday last. Alderman Firth moved a resolution that application be made by the Council, as the local authority under the Tramways Act, 1870, for a provisional order authorising the construction of various lines of tramways. Mr. Graham, who had on the agenda an amendment, stated that it was that no extensions of the tramway lines be proceeded with until the system of haulage in the different districts was decided upon. Ultimately the resolution and amendment were withdrawn, and the special meeting was concluded. The adjourned meeting to dispose of the remainder of Friday's business was then held. The question of the tramways was then further considered, Alderman Firth, for that purpose, moving the suspension of the standing orders. Alderman Firth moved: "That the Council apply to Parliament in the ensuing session for a Bill empowering the Corporation to construct additional tramways in Leeds and at Roundhay Park, and that the requisite notice of such application be prepared and published in the manner required by the standing orders of Parliament." Alderman Boothroyd seconded the resolution. After some discussion, Mr. Battle moved the following addition to the resolution: "That in the application to the next session of Parliament for an extension of the city tramways, clauses be inserted giving power to the Corporation to place or run carriages upon the city tramways, including such extensions, and to demand and take tolls and charges in respect of the use of such carriages." Eventually the addition and resolution were adopted.

Richmond.—The Town Council have adopted the recommendation of the Finance Committee that the sum of £1,000, with accrued interest thereon, should be paid to the Richmond Electric Light Company in return of their deposit under a clause of their contract with the Corporation, the same having been duly performed as far as was material to this purpose. The following report was also agreed to: "The question of the recovery from the electric light company of three several sums outstanding for work done for them by the Corporation has also been before the committee. Under Clause 6 (*h*) the Corporation has power to deduct these sums from the amount of £400 deposited under the same clause, as security for certain work to be done by the Corporation on account of the company. This course has already been adopted on two previous occasions, and in view of the delay experienced in recovering these payments from the company, the committee recommend that the sum of £22. 12s. 1d., due to the Corporation from the Richmond Electric Light, etc., Company, for work done up to Michaelmas, 1894, be deducted from the balance of the £400 deposited by the predecessors in title of the company, under their contract with the Corporation. On deduction of the sum in the last preceding paragraph mentioned, the balance of the £400 deposit will be reduced to £62. 12s. 6d. By Clause 6 (*h*) of the contract, the Corporation are not bound to perform any work for the company when the deposit is reduced below £400, or payments due from the company to the Corporation have been outstanding for more than seven days. Under these circumstances the committee recommend that the Council call the attention of the Richmond Electric Light, etc., Company to Clause 6 (*h*) of their contract, and request them to make up the deposit therein required to the specified sum of £400."

Taunton.—Mr. Harold W. Couzens, the borough electrician, in his quarterly report to the Town Council stated: "I have the honour to report that the demand for light has been steadily increasing until, at the present time, we have no more small transformers in stock to supply new consumers until No. 2 sub-centre is in operation. At the present time we are using about 25 per cent. less coal than during the corresponding period of last year, whilst our output is much greater. We have now the equivalent of 2,000 16-c p. lamps connected to our mains, exclusive of arc lamps, of which 224 have been added during the past quarter." The Electric Light Committee presented the following report, which has been approved of by the Town Council: "Your committee recommend the Council to enter into an agreement for two years with the Syndicate of Electrical Engineers (?) for receiving from their institution students for the electric lighting works. The committee herewith present the form of agreement, and recommend that the common seal of the borough be affixed thereto. Your committee report that Mr. R. W. Phillips, assistant electrician, has left the works, having obtained another appointment. The committee recommend that Mr. E. B. Thornhill be promoted to Mr. Phillips's place, at a salary of £67 a year, and that Mr. E. R. Shand (a former pupil) take Mr. Thornhill's place, at a salary of £55 a year. The committee also recommend that Mr. A. E. P. Witham be raised from £20 to £30. The foregoing arrangement will make an increase of £2 a year An application has been received from Mr. Bessemer to have the electric light installed at his house at Highlands. The committee recommend that the necessary wire be laid in order to give such supply." Notices have been received from the Local Government Board that Colonel John Ord Hasted, R.E, one of the Board's inspectors, was to hold an enquiry on Tuesday last, the 13th inst., as to the application from the Council for sanction to borrow £5,000 for purposes of electric lighting.

Cheltenham.—The minutes of the Electric Lighting Committee of the Town Council stated that the Mayoress wrote expressing her thanks for the handsome silver trowel presented to her on the occasion of her laying the memorial stone of the electric lighting station. The electrician, Mr Kilgour, reported that the wiring orders had been placed in tradesmen's hands for 450 16-c.p. lamps, and that orders for another 300 would be given in the course of a few days. Mr. T. Whittard, hon. sec. to the officers of Salem Baptist Church, wrote stating that it was intended to introduce the electric light into the chapel, lecture-room, etc., and making certain suggestions on public and economic grounds for churches, chapels, and other large public buildings. It was decided to refer Mr. Whittard's letter to the borough surveyor to report thereon. It was resolved to request the Public Library Committee to consider the question of introducing the electric light into the library. The surveyor reported that the transformers having been ordered, and the sub-stations commenced, it was necessary that the order for switchboards should be placed. The quotations were: the Brush Company, £210. 4s. 6d.; Messrs. Siemens Bros., £376; and he advised the acceptance of the Brush Company's offer, their apparatus being simple and effective. For testing the alternators, transformers, and meters, an artificial load consisting of 100 incandescent lamps would be required, costing between £90 and £100. They should also require from Messrs. Callender, who were supplying the cables, 20 sub-station joint-boxes at a cost of £76. As there were already 14 certain customers, he recommended that an order for 20 meters be placed at once. Three hundred and fifty pounds was due to the Corruganza Manufacturing Company on account of contract for paper tubes. It was resolved to accept the tender of the Brush Company for switchboards, and to purchase the other apparatus mentioned in the surveyor's report. The following members of the new Town Council have been appointed as the Electric Lighting Committee: the Mayor, Aldermen Thoyts and Norman, Councillors Dimmer, Lawrence, Parsonage, H. Waghorne, and Wheeler.

Derby.—The Electric Lighting Committee report that the whole of the arc lamps for street-lighting (76) are now in position. The total candle-power of street gas lamps displaced by these is 9,072. The effective light produced by the arc lamps amounts to at least eight times that of the gas lamps displaced. The price of electric current for purposes other than lighting has been reduced to 3d. per Board of Trade unit. Mr. F. L. Lister has been appointed assistant engineer, and Mr. Reginald S. Downe second assistant. Messrs. Siemens Bros. and Co., Limited, handed over the working of the station to the committee's staff on August 25 last, since which time it has been entirely worked by such staff. The mains and public lamps are still in the hands of the contractors. The engineer (Mr. Stewart) has been allowed to take two pupils instead of one. Contracts for coal have been let to Messrs. Eckersley Bros., Messrs. Steer and Smith, and Mr. Pepper. Thirty additional meters have been ordered. It has been found necessary that the staff sanctioned by the Council on February 7, 1894, should be rearranged and added to, and there are now employed in addition to the staff authorised by the Council the following officers: a second assistant engineer, a driver, and a greaser. Continuous running is now carried out in accordance with the provisions of the lighting order, and the work is done in three shifts. The private lighting, the committee consider, promises to be a good business success. It is, of course, premature to positively make any statement, but when it is remembered that the present installation, so far as private lighting is concerned, is designed for 7,500

Digitized by Google

lights, and that 7,450 lights are already attached, and there are signed applications for 3,000 lights more, the conclusion that the public show a distinct inclination to take the light is inevitable. The committee regret that they cannot at present settle their accounts with the contractors, so that the exact amount of capital and annual expenditure can be ascertained, but they need hardly tell the Council that this will be done at as early a moment as possible. The expenditure of the committee is still within the amount granted by the Council (£35,000), but further expenditure will undoubtedly be necessary. The 250-h.p. engine and dynamo combined is now nearly completed, but the demand for current for domestic and business lighting purposes is already sufficient to absorb all that it will produce in addition to the plant already at work. The machinery cannot well be increased to be of much service during the present winter, but early in spring the matter must have attention.

PROVISIONAL PATENTS, 1894.

NOVEMBER 5.

21185. **Improvements in oil, gas, electric, and other light pendants.** Charles Thomas Powell, 12, Cherry-street, Birmingham.

21202. **An electrical typewriter.** George Cockroft Walker and Thomas Smith Paynter, 73, Wroughton-road, Balham, London.

21218. **Improvements in electrical switches.** Charles Philipp Ehmann, 106, Meadow-street, Moss Side, Manchester.

21244. **Apparatus for electrically signalling from the locomotive to the carriages of a railway train.** Max Zvee Levy, 89, Chancery-lane, London.

21250. **Improvements in or relating to multiple telegraphic apparatus.** Alfred Piedfort, 323, High Holborn, London. (Complete specification.)

NOVEMBER 6.

21323. **Improvements in apparatus for welding electrically.** William Phillips Thompson, 6, Lord-street, Liverpool. (Charles Lewis Coffin, United States.) (Complete specification.)

21330. **Improvements in galvanic batteries.** Georg Hübner, 115, Cannon-street, London. (Complete specification.)

21347. **Improvements in systems of telegraphic or telephonic exchanges.** Wallace Childs, 70, Chancery-lane, London. (Complete specification.)

21353. **Improvements in electric motors for railway vehicles.** Harvey Slaughter Park, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

21366. **Improvements in connection with electrically-propelled vehicles for running on ordinary roads.** Frank King, 47, Lincoln's-inn-fields, London.

21367. **Improvements relating to the connections of battery receptacles employed in electrically-propelled vehicles.** Frank King, 47, Lincoln's-inn-fields, London.

NOVEMBER 7.

21410. **Improvements in and connected with electrical apparatus for signalling on railways.** William John Rawson, 78, Fleet-street, London.

21439. **Electrical sewer ventilator.** Ernest Matthew Lacey, 19, Old Queen-street, Westminster.

21446. **Improvements in electric meters.** Clement Johnson Barley, 45, Southampton-buildings, Chancery-lane, London.

21452. **Improvements in automatic electric fire alarms and signals.** Percy Richard Julius Willis, 55, Chancery-lane, London. (Louis Aloysius Werner and Clement Julius Werner, United States.)

21461. **Electric motors.** Charles Riordon, 4, South-street, Finsbury, London. (Complete specification.)

NOVEMBER 8.

21482. **Improvements in recording apparatus for ships' telegraphs.** Ellis Fletcher, 4, Clayton-square, Liverpool.

21489. **An electric track machine for railway system.** Edward Deming, 57, Barton-arcade, Manchester. (Complete specification.)

21531. **Improved electric sash-balance.** William Candler Hodgkins, 55, Chancery-lane, London.

21549. **Improvements in electrically-heated robes, towels, quilts, and other articles of flexible fabric.** Henry G. O'Neill and Edward Jewell, 65, Chancery-lane, London. (Complete specification.)

NOVEMBER 9.

21555. **Improvements in secondary batteries.** Illius Augustus Timmis, 2, Great George-street, Westminster.

21613. **Improvements in telephones.** Edgar Charles Parker, 55, Chancery-lane, London.

21629. **Improvements in and relating to electric railways.** Ludwig Hanisch and the Hoerder Bergwerks and Hütton-Verein, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

21630. **Improvements in electric meters.** Heinrich Leupold, 45, Southampton-buildings, Chancery-lane, London. (Harry Leupold, Italy.)

21640. **Improvements in or connected with electric switches.** George Jacob Gurl, 4, South-street, Finsbury, London.

NOVEMBER 10.

21684. **Automatic hydro-electric indicator and alarm.** Horace Dando, 9, Sanfoin-road, Upper Tooting, London. (Henry Augustus Dando, New Zealand.)

21707. **Improvements connected with the electric conductors of electric railways.** Alfred Slater, 6, Bream's-buildings, Chancery-lane, London. (John Platt, United States.) (Complete specification.)

21731. **Improvements in arc lamps.** Charles Aubrey Day, 321, High Holborn, London. (George Joseph Schoeffel, United States.) (Complete specification.)

21750. **Improvements in arc lamps.** James William Rogers, 24, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1893.

19427. **Electrical toys.** Myers.

20837. **Electrical measuring instruments.** Ayrton and Mather.

22876. **Electric switches.** Hopkinson.

23211. **Electro-mechanical governors.** Goolden and Lewis.

23605. **Attaching reflectors to electric lampholders.** Ebbutt and Verity.

24001. **Thermo-electric lubricating apparatus.** Coombes. (Coombes.)

24081. **Electrical carbons.** Niewerth.

24217. **Electrical measuring instruments, etc.** Ayrton and Mather.

24276. **Electrolytic apparatus.** Guthrie.

24353. **Electric accumulators.** Mills. (Barbier,)

24389. **Secondary battery plates.** Lehmann.

24442. **Electrical accumulator plate.** Mills. (Barbier.)

13066. **Incandescent gas or electric light mantles.** Boult. (Steur.) (Second edition.)

15669. **Electrolytic treatment of liquids.** Brown. (Vogelsang.) (Second edition.)

1894.

17296. **Dynamo-electric machines.** Lake. (Eickemeyer.)

NOTES.

Mill-Lighting.—It is stated that English weavers are taking great interest in the electric lighting of their mills.

Telephony in Germany.—It appears that telephonic connection between Berlin and the East will be extended to Memel *viâ* Tilsit.

Electric Lighting in Russia.—Proposals have been received by the Municipality of Jalta for the electric lighting of the town.

Electric Traction in Switzerland.—A project is being discussed in Switzerland for an electric mountain railway up the Jungfrau from Guyer-Zeller.

Electric Lighting in Switzerland.—A central electric light station is to be erected at Ruppoldingen. Messrs. Brown, Boveri, and Co. are interested in the scheme.

Northern Society of Electrical Engineers.—A smoking concert of this society will take place at the Palatine Hotel, Hunt's Bank, Manchester, this (Friday) evening, at 8 p.m.

Lord Armstrong.—The Christmas number of *The Tyneside*, published at 75, Pilgrim-street, Newcastle-on-Tyne, will contain as a presentation plate an ink photo of Lord Armstrong.

Electric Lighting in Spain.—The municipal authorities of Guadalajara, a town of 8,500 inhabitants, near Madrid, are open to receive offers for the introduction of the electric light into the town.

Telegraphy in the Straits Settlements.—The telegraph land line, which the Straits Government propose to erect between Singapur and Malacca, through the territory of Johore, will be put in hand at once.

Electric Traction in Austria-Hungary.—Good progress is being made in connection with the underground electric railway, which is being built by Messrs. Siemens and Halske at Budapest, from Stadtwäldchen to the Donauquai.

Presentation.—The representatives of the staff of the submarine cable companies over which Sir John Pender presides have presented him with a silver trophy to mark the twenty-fifth anniversary of cable communication with the Far East.

Hermann von Helmholtz.—A lengthy obituary notice, dealing with the life and work of Hermann von Helmholtz, whose death, as mentioned at the time, took place on the 8th of September last, is published in the *Elektrotechnische Zeitschrift* of November 8.

Civil and Mechanical Engineers' Society.—The members of this society on Friday last visited the works of Messrs. Bullivant and Co., in the Isle of Dogs, where the processes of making steel wire cables and ropes, torpedo-catching nets, and wire netting is carried on.

Obituary.—The death is announced, at the age of 95, of Mr. Robert Davidson, of Aberdeen. The deceased is credited with having constructed, among other electrical apparatus, a storage battery locomotive as long ago as 1839, which was tested on the Edinburgh and Glasgow Railway.

Sunderland Exhibition.—On Monday there was opened at Sunderland a marine, electrical, and engineering exhibition in the Artillery Drill Hall. There are about 300 exhibitors. The buildings are lighted electrical ly by Messrs. Ernest Scott and Mountain. The exhibition will remain open for two months.

Royal Institution.—The Christmas course of lectures, adapted to children, will be delivered by Prof. J. A. Fleming, F.R.S., professor of electrical engineering in University College, London. The subject will be "The Work of an Electric Current," and the first lecture will be delivered on Thursday, December 27, at three o'clock.

Shocks.—An arc lamp trimmer in Blackpool received a shock last week whilst attending to a lamp in the street. From the newspaper account it appears that he had not switched off the current in the base of the lamp before attempting to trim the lamp. At Keswick a broken wire is reported to have been the cause of several persons being slightly shocked.

Light Railways.—In response to the invitation from the Board of Trade, the London Chamber of Commerce have nominated Sir Edward H. Carbutt, Bart. (chairman of the Engineering and Allied Trades' Section), and Mr. Emil Garcke (chairman of the Electrical and Allied Trades' Section) as the delegates of the Chamber to the conference on light railways, which is to meet early next month.

Physical Society.—At the meeting of this society to be held to-morrow afternoon at the rooms of the Chemical Society, Burlington House, the following papers will be read: (1) "The Measurement of Electromagnetic Capacity,' by Mr. Fred. Womack; (2) "Mirrors of Magnetism," by Prof. Silvanus P. Thompson and Miles Walker; and (3) "Students' Simple Apparatus," by Prof. W. E. Ayrton and others.

Trans-African Telegraph.—According to Reuter's agency, Mr. Cecil Rhodes states that the Salisbury-Tete section of the trans-African telegraph has advanced 100 miles, leaving still 100 before the link is completed. He is of opinion that the wet season now coming may prevent its completion till after the rains. The material for the line is at Salisbury. It is officially announced at Cape Town that Blantyre and Tete are now connected by telegraph, thus bringing London within a week of Blantyre.

Utilisation of Water Power.—We have received a copy of a pamphlet by Mr. John Ritchie, hydraulic engineer, Edinburgh, on "The Utilisation of Water for Power and the Transmission of Same," and on "Improved Turbines for the Utilisation of Water for Power," these treatises being reprints of papers read last year before the Royal Scottish Society of Arts, and which were awarded the Keith medal and prize of £5. The author advocates a more extended application of water power in Scotland for electric lighting purposes.

Moving Sidewalks. — A sub commission of the universal exhibition to be held in Paris in 1900 met last week at the Ministry of Commerce to consider various proposals brought forward in connection with the exhibition. One of the schemes suggested is by M. Blot, of Paris, for a moving sidewalk, similar to that at the Chicago Exhibition, to be worked by electric power within the grounds. Another project—this by MM. Casalonga and Faure, of Paris—is for the construction of a metropolitan railway operated on the same principle.

Telephony in Germany.—Application has been made from Frankfort-on-the-Maine to the Imperial postal authorities that when telephonic communication is shortly established between Frankfort and Berlin, the two lines between Frankfort and Berlin, and between Frankfort, Cassel, Nordhausen, and Berlin should be reserved from 12 noon till 3 p.m. for the use of members of the exchanges. This has not been agreed to, the authorities considering that such a course would be unfair to telephone subscribers who are not members of the exchange. A new telephone exchange has been established at Moabit, Berlin.

Digitized by Google

Electric Motors on War Vessels.—Whilst the English Admiralty have almost, if not entirely, refrained from installing electric motors on British men-of-war for the operation of heavy guns, the French Naval Administration have recognised the important part which this type of motor may be expected to play in the ready manœuvring of such weapons. As an instance of this fact, it may be mentioned that four of the latest French armoured cruisers are not only equipped with electric motors for the working of the guns, but also for the operation of the turrets.

New Mains in London.—The London County Council have approved of the City of London Electric Lighting Company laying additional mains on the west side of Southwark Bridge-road; of the House-to-House Company laying high-tension mains across Warwick-road into Longridge-road; of the Westminster Company to lay mains in Carrington-mews and across and along Little Stanhope-street; and of the Woolwich District Company to lay mains across Powis-street and in Eleanor-road. The Council have declined to allow the City Company to lay mains and construct street boxes in a part of Tower-hill, on the ground that the works would be outside the company's area of supply.

Royal Meteorological Society.—The opening meeting of the session was held on Wednesday at the Institution of Civil Engineers, Westminster, Mr. R. Inwards, F.R.A.S., president, in the chair. Dr. H. B. Guppy read a paper on "Suggestions as to the Methods of Determining the Influence of Springs on the Temperature of a River as Illustrated by the Thames and its Tributaries." Mr. Eric S. Bruce, F.R.Met.Soc., exhibited and described some lantern slides showing the disastrous effects of the great gale of November 17 and 18, 1893, upon trees in Perthshire, Scotland. Mr. Alfred B. Wollaston gave an account of the formation of some waterspouts which he had observed in the Bay of Bengal.

The Electric Light in Ceylon.—It has been definitely decided to light the new post office at Colombo with the electric light. In the illumination of the building 28 arc lamps will be used, and about 100 incandescent lamps. Twelve arc lamps will be used outside the building. Round the pavement in front of the post office there will be eight fancy lamp-posts bearing lights, while four others will be placed at the corners of the building outside. Then there will be four arc lamps in the main hall and eight in the sorting department. There are two sets of residential apartments within the building, and these will also be lighted by incandescent lamps, while all the other parts of the building will be illuminated in the same way.

Electrocution in America.—We referred to this subject last week. Another Dalziel's message now says: "There is great public indignation at the decision of Governor Flower to allow the body of the murderer Wilson, who is shortly to be electrocuted at New York, to be experimented upon immediately after the execution with the idea that life may be restored. Governor Flower has promised Wilson's attorney that in the event of resuscitation the man's life shall be spared, and Wilson himself clings to the only hope left him, and has expressed his gratitude to the governor for the remote chance of life given to him. A petition, which is being extensively signed, will be presented to the governor praying him not to allow the experiment to be made. Public feeling in the matter runs high."

Electric Traction in Germany.—A new project for an electric tramway to open up the Grunewald, Berlin, has been prepared by Messrs. Havestadt and Contag. It is proposed to start from the Nollenplatz.—The Allgemeine Deutsche Kleinbahngesellschaft, of Berlin, who own the Spandau tramways, have come to an agreement with the local authorities whereby electric traction will be adopted on the line. The work will be carried out by the Allgemeine Electricitäts-Gesellschaft, and the overhead trolley system will be employed.—An extensive system of electric tramways is to be established at Aix-la-Chapelle, where not only are the existing horse tramways to be changed into electric lines, but several new lines are to be built for electric traction.

Another Competition of Self-Contained Vehicles. A French contemporary states that it is proposed to organise a new competition of self-contained carriages, and that the comfort of passengers will not be studied as in the case of the *Petit Journal* contest, but that awards will be made to those competitors whose vehicles attain the highest speed on a long route. The minimum distance to be traversed is 620 miles; the start will be made from Paris, to which city the carriages will return; and the vehicles admissible to the competition must be operated either by an electric motor, a steam-engine, or a petroleum or similar motor. An organising committee has already been formed, and it is intended to arrange for the competition taking place next year.

Curious Octroi Process.—The town of Roubaix, according to *L'Energie Electrique*, levies tolls, or octroi duty, on coal for the gasworks and on petroleum, but industrial coal for the spinning mills is exempt. As the majority of the works provide their own light by running dynamos, the town claimed the right to tax the coal used for this particular purpose. Three of the manufacturers, acting for all those whose premises are electrically lighted, thereupon commenced an action against the town for the return of the money paid as octroi duty. The case was decided in favour of the manufacturers, and this decision has been confirmed by the Tribunal Civil de Lille. The town, however, now intends to carry the case to the Court of Appeal.

Sliding Roofs for Theatres.—A new theatre and concert-hall have been erected on the site of the former concert-hall known as "La Cigale" in the Boulevard Rochchouart, Paris. The buildings are lighted by 500 incandescent lamps, the current being obtained from the Edison Company's station in the Avenue Trudaine. Not only this, but on the suggestion of Mr. E. Pacoret the proprietors have had two electric motors installed for the operation of the sliding roof. The roof is divided into two parts, which form travelling bridges, each of which is equipped with an electric motor of 1 h.p. running at 1,000 revolutions. By means of gearing the travel of each half of the roof is effected, and alarm bells are automatically caused to ring on each half reaching its proper position.

Electromotive Force of Alloys in a Voltaic Cell.—Before a recent meeting of the Chemical Society Mr. A. P. Laurie, M.A., read a paper on this subject. The paper contains the results of determinations of the E.M.F. of 16 of the 19 alloys alluded to in Matthiessen's paper on the conductivity of alloys (*Phil. Trans.*). The results obtained confirm Matthiessen's conclusions, that only one compound, the tin-gold alloy, exists among the 16, which are: bismuth-tin, bismuth-lead, bismuth-gold, bismuth-silver, gold-silver, antimony-lead, cadmium-zinc, antimony-tin, lead-gold, lead-silver, lead-tin, lead-zinc, lead-cadmium, and cadmium-tin. In some cases the addition of a metal to the alloy results in displacement. Thus mercury decomposes the gold-tin compound, and zinc, added to copper-tin alloy, appears to replace the tin.

Telephony between England and Holland.—An application has been made to the London Chamber of Commerce by the Netherland Chamber of Commerce in

Digitized by Google

London for information as to whether a trade requirement would be met by, and, commercial support given to, a telephone line between London and Holland, if such were established. The Netherland Chamber state that it would be possible to carry out the project by laying a line *vid* Dover to Sangatte, Dunkirk, Antwerp, Roosendaal, and Dordrecht to Rotterdam and Amsterdam. In order that the council of the London Chamber of Commerce may comply with the request of the Netherland Chamber, the secretary has sent out forms to members asking whether they think the establishment of telephonic communication with the Netherlands would be appreciated, and whether if such a means of communication were available, they would have occasion to use it.

Submarine Electric Boat.—Judging from the long interval that has elapsed since we last heard of the French and Italian submarine electric boats, the conclusion was naturally arrived at that they had gone to Davy Jones's locker. It appears, however, that this conclusion was too hasty, at least in regard to one of the French boats, which was tested again last week. This is, according to a *Times* correspondent, the "Gustave Zédé." She is a cigar-shaped vessel, 131ft. long, and displacing, when submerged, about 266 tons. On Wednesday of last week she moved about the roadstead at Toulon for three hours, never, however, as far as could be seen by those who were watching her from the shore, going beneath the surface. She attained a speed first of about five knots, and subsequently of about eight knots, with the 300 new accumulators with which she has been recently fitted. Her turning circle was found to be 700ft. or thereabouts. It appears that, although the boat was probably not submerged for a single moment, those on board experienced some discomfort from the acid vapours disengaged, and that submersion for more than a few minutes, the correspondent concludes, will be impossible unless measures can be devised for correcting this inconvenience.

Electric Lighting in Germany.—The central electric light station at Weissenfels is to be opened next month.—The Municipality of Plauen have under consideration the question of establishing an electric light station.—The local authorities of Kastel have arranged with Messrs. M. Schorch and Co., of Rheidt, to light the streets electrically.—It is expected that the central station at Goldberg, Silesia, will be ready about February.—The electric light mains at Munich are to be extended.—Application has been made by a local syndicate to the Municipality of Traunstein for a concession to use the water power of the Traun for electrical purposes. It is stated that from 200 h.p. to 250 h.p. could be obtained at small expense.—The local authorities of Königstein have determined to erect a central electric light station.—Messrs. Scheidt and Witzsche, who light their works at Grosblittersdorf electrically, have made an offer to the local authorities for the electric lighting of the streets.—It is proposed to light the streets of Alberschweiler, in Lorraine, electrically.—The Municipality of Strasburg, West Prussia, have adopted the proposal of the Helios Company for the erection of a central station.—The Lebus sugar factory at Frankfort-on Oder has been lighted electrically.

Paris Central Electrical Laboratory.—A few weeks ago we described the scope of the Laboratoire Central d'Electricité, which has been established for some time at 12 and 14, Rue de Stael, Paris. We now learn that to the laboratory has been added an Ecole d'Application, the object of which is to afford practical information to engineers in the extended employment of electricity in industrial operations. Students of any nationality and of any age will be admitted. Those candidates who are provided with diplomas which are not recognised as sufficient, will have to undergo an examination in electricity, and in a knowledge of mathematics, mechanics, and physics. The fees, which are payable in advance, amount to 200f. (£8), of which one half is to be paid on entrance and the other half on the 1st of March. The instruction will comprise (1) a course of from 30 to 35 lessons in industrial electricity; (2) a course of from 20 to 25 lessons on electrical instruments; (3) a series of lectures on special questions; (4) practical electrical work; (5) workshop work; (6) the establishment of industrial installations; and (7) visits to works. The lessons and lectures will take place between 9 a.m. and noon; laboratory and workshop work will either be in the morning or afternoon. An examination of the students by the professors will be held in the middle of the year, and a second examination will also take place. The session will open on December 3 next.

Society of Arts.—The one hundred and forty-first session of the Society of Arts was opened on Wednesday evening, when Major-General Sir John Donnelly, chairman of the council, delivered an address, in the course of which, having mentioned the society's efforts in establishing drawing and modelling schools for artisans, and in promoting in 1852 the union of institutions to aid and develop the work of the literary and scientific institutions and mechanics' institutes, he referred to the establishment in 1872 by the society of examinations in technology, which had since been developed by the City and Guilds of London Technical Institute. The examinations of the Society of Arts and those of the City and Guilds Institute did not now overlap, but were complementary one of the other. Their own examinations were literary and commercial, while those of the institute were in the technology of trade and manufactures. In conclusion, the chairman suggested that the Society of Arts should undertake the initiative in bringing together the various bodies concerning themselves with the question of technical education, so that they might form some kind of joint Board, or at least co-operate in the general interests of the movement. The chairman afterwards distributed the society's silver medals awarded for papers presented during the past session. The paper at next Wednesday's ordinary meeting will be on "Experiments in Aeronautics," by Mr. Hiram Maxim."

Electrical Apparatus.—A glance through the new illustrated catalogue just issued by Messrs. Dorman and Smith, of Ordsal Electrical Works, Salford, and of 11, Grocers' Hall-court, London, E.C., shows the large variety of electrical appliances made by the firm. Commencing with an assortmsnt of holders for different kinds of lamps, the list passes on to guarded and shaded iron reflectors, and to the "D. & S." (new series) porcelain switches. These switches are made entirely of porcelain and metal, no fibre or other semi-insulator, liable to be affected by damp, being used. In addition to these, carbon break switches, switches for house service, single and double pole main switches, and main switchboards occupy a prominent position. These are followed by porcelain cut-outs, distributing fuse-boxes, resistances and regulators, and wall sockets and socket connections for heavy currents. Dealing with fittings, some neat and handy balanced suspension pendants are shown, together with a variety of plain brackets, cast-iron mill fittings, universal fittings. A new series of strong brass fittings for ships is illustrated. In this case a flanged well glass is used, and being held up against an indiarubber ring a watertight joint is made. The guards of these fittings are made of wrought-brass tape, and are exceedingly strong and graceful in appearance. They are stocked finished in steel

Digitized by Google

bronze, but can be made of polished and lacquered brass when required. The Raworth and the "D. & S." bobbin detectors bring this catalogue to a close.

Length of Electric Tramways in Europe.—It has for many months past been extremely difficult to follow the complications attending the different schemes for the construction both in Berlin and Vienna of underground and surface electric railways. Nevertheless, the question has recently been taken up prominently by the Vienna Elektrotechnische Verein, who have made some excellent suggestions for improving the facilities of transport in that city by the introduction of electricity as the motive power. Not only this, but the Verein has now been supported by the Verein für die Förderung des Local und Strassenbahnwesens. One of the members of the latter, Mr. Ziffer, referred particularly a few days ago to the report presented by Mr. Paul van Vloten at the meeting in August last of the Permanent International Tramway Union. It appears that Mr. van Vloten investigated on behalf of that union all the important electric tramways in Germany, France, Italy, and Switzerland, subsequently drawing up an exhaustive report on the subject. The following table, extracted from that report, shows the position of electric traction in different European countries at the close of 1893:

	In operation.	In construction.	Total.
Belgium	3·2	18·5	21·7
Germany	102·0	66·1	168·1
England	71·4	21·4	92·8
France	41·4	29·0	70·4
Italy	13·0	—	13·0
Holland	4·9	—	4·9
Austria-Hungary	33·4	—	33·4
Roumania	—	5·5	5·5
Russia	3·0	7·0	10·0
Sweden and Norway	—	6·5	6·5
Switzerland	23·6	10·6	34·2
Servia	—	10·0	10·0
Spain	14·0	—	14·0
Total	309·9	174·6	484·5

Lamps Supplied v. Lamps Installed.—Some interesting statistics were recently brought under the notice of the German Gas and Water Union by Messrs. Bunte and Rasch in regard to the development of electric lighting in Germany. The authors calculated and grouped the number of incandescent lamps installed in the cases of private installations and central stations per 1,000 inhabitants, the towns concerned having populations exceeding 100,000 persons. Arc lamps are each reckoned as equivalent to 10 incandescent lamps. The following few instances will illustrate the number of lamps installed per thousand inhabitants: Aix-la-Chapelle, 77; Berlin, 80; Hamburg, 108; Hanover, 126; Magdeburg, 148; Munich, 192; and Frankfort-on-the-Maine, 193. Very interesting are the following figures, which show the percentage of lamps supplied as compared with the total number of lamps installed: Aix-la-Chapelle, 43 per cent.; Berlin, 60 per cent.; Dusseldorf, 62 per cent.; Elberfeld, 88 per cent.; Hamburg, 19 per cent.; Hanover, 39 per cent.; and Stettin, 71 per cent. An average of 12 towns gives a percentage of 52 per cent. In order to draw a proper conclusion from these statistics it is necessary to ascertain (1) how long the central station has been in operation; (2) if the mains extend throughout the town or only in a part of it; and (3) if there are many industrial establishments where private generating plant is in use. The authors state that out of the total number of lamps installed in Germany, only one quarter is supplied from central stations, and they conclude that with the extension of similar investigations it will be found that this proportion will prove to be less favourable to central stations because a number of works in the same locality will put down their own plant.

Railway Rates.—The council of the London Chamber of Commerce have decided to support, and to financially assist, the executive committee of the Mansion House Association on Railway and Canal Traffic, in bringing test cases for the purpose of determining, as far as may be practicable, the reasonableness of the general increase in railway rates, and with the object of clearing up several other points of great interest to traders arising out of the Railway and Canal Traffic Act passed last session. To prosecute this course of action successfully, it will be necessary to obtain the assistance of leading members of the legal profession. Neither the Chamber nor the association have at their disposal ordinary funds which can be diverted to this object. The council point out that there can be little doubt, however, that the "test cases" will be the means of saving, not only immediate but future heavy expenses to traders, and they therefore appeal to members to subscribe to a guarantee fund, in accordance with a form issued to members. At the same time these test cases cannot be held to obviate, as a matter of course, the necessity for the submission of complaints to the Board of Trade on the part of those who desire to establish their title to deductions which they have made from the railway companies' accounts, or to recover increases which they have paid. Members who desire to avail themselves of the Act of 1894 are therefore recommended to complain to the Board of Trade without delay as the best means of avoiding legal proceedings at the instance of the railway companies, and upon this point it must be borne in mind that, if it is desired to obtain from the railway companies damages in satisfaction of over-charges made prior to the passing of the Act, complaint must be made to the Board of Trade not later than February 25, 1895.

Double-Voltage Dynamo.—A new machine called the Fuller double-voltage, automatic, constant-potential dynamo, has been brought out by the Fontaine Crossing and Electrical Company, Detroit, Mich., for which a number of advantages is claimed. Among these, according to the *Electrical World*, are that the dynamo can be connected to any three-wire system without alteration in wiring throughout the building, and used equally as well with a two-wire system and for either of two voltages. For example, in a 100-h.p. generator the current can be taken at 110 volts or at 220, while any intermediate number of horse-power from zero to full load can be taken at either voltage or both at the same time. The dynamo is, in fact, practically two machines in one. The company guarantees all machines to regulate within two volts from zero to full load with brushes practically at a fixed point of commutation. Particular attention has been given to the mechanical construction of this machine, ensuring long life, as the bearings are long and large in diameter. The field windings are of high resistance, while the armature windings are of low resistance, ensuring long life, from the fact that heating is almost entirely avoided. The bearings are self-oiling and self-aligning, ensuring perfect lubrication. The advantage of this machine is particularly apparent where 220-volt motors are in use, and it is desired to put in a lighting plant, as in this case the motors can be supplied with a 220-volt current, and the lighting circuits yet run at 110 volts. In large cities, where floor space is valuable, it is obvious that where one machine is put in to do the work of two the expense is greatly decreased. There is one foundation dispensed with, one belt and one clutch pulley, as well as the actual floor space saved. In the ordinary system of lighting and power service,

Digitized by Google

where two voltages are desired, it has always been necessary to couple two machines in series, thus making the first cost of the plant extremely high. While the cost of a dynamo of this description is slightly higher than a single-voltage dynamo, it is low when compared with the cost of two machines.

Electric Traction in Egypt.—A telegram from Cairo states that the Council of Ministers have granted a concession for the construction of an electric tramway in the city to a Belgian syndicate. It will be remembered that tenders for this line were invited some time ago. It appears, however, that a dispute has arisen in connection with the undertaking, as is shown by a further dispatch from Cairo. The telegram states that the concession, which was granted to the Société Belge des Chemins de Fer Economiques, will probably be rescinded or suspended by order of the British Government, until the appeal of Mr. John Fell, of Leamington, the late concessionaire, has been heard by the Mixed Tribunal, or till the Egyptian Government agree to pay him sufficient compensation to induce him to withdraw his case from the Court of Appeal. It is submitted that by the terms of the new concession the Belgian company was to refund the £2,000 deposit which Mr. Fell had originally lodged with the Egyptian Government, but a new face having been put upon Mr. Fell's case by a correspondence between Lord Kimberley and the British Agency, it is considered likely (the telegram continues) that the Administration will consent to refund several thousand more of the claim for expenses which were incurred under the first concession rather than throw over the Belgian company, who hold an advantageous tender. From the information in possession of the British Agency, the authorities there were enabled to supply Lord Kimberley with particulars as to Mr. Fell's claims, and the matter is now in Mr. Fell's hands. It is thought that the Egyptian Government misrepresented the facts in their endeavour to convince the Foreign Office that the claim of that firm was groundless. In this information, it is alleged, an official copy of the letter from Sir Colin Scott Moncrief to Mr. Fell, dated 1891, appears with the words "Under Secretary of State" suppressed, and without a registered number, and a telegram from the Alexandria Customs authorities is produced denying the existence in the Customs at the time of a cargo of rails to Mr. Fell's address. From this apparently crooked dealing it is thought that the British Government will interfere, and insist upon a fair compensation being granted by the Egyptian Government to Mr. Fell.

Decimal System of Weights and Measures.—The New Decimal Association, which has been established to promote the adoption of a decimal system of weights, measures, and coinage in the United Kingdom, met on Tuesday at the offices of the London Chamber of Commerce. Sir Samuel Montagu, M.P., presided, and amongst those present were the Right Hon. Sir J. W. Mellor, M P. (representing the Halifax Chamber of Commerce), Mr. H. O. Arnold Foster, M.P. (Belfast Chamber of Commerce), Mr. E. H. Bayley, M.P., Mr. Alex. Siemens, Sir Philip Magnus, Mr. Thomas Kyle (Incorporated Society of Inspectors of Weights and Measures), Mr. A. J. Hamilton Smythe, M.I.C.E., Mr. Frank Debenham, Mr. Martin Wood, etc. The Chairman mentioned that the association proposed to confine the present movement to weights and measures, and not deal with the subject of decimals in money. Sir Albert K. Rollit, M.P., proposed the following resolution: "That this association learns with satisfaction that the Government consents to the appointment of a Select Committee to enquire whether any and what changes in the present system of weights and measures should be adopted, and the executive committee is hereby authorised to take such steps as it may consider best for promoting the adoption of the metric weights and measures." He remarked that we occupied an isolated position with weights and measures in reference to international trade. The metric system was used by 400,000,000 of people, with some 60 or 70 per cent. of whom we did business, and our system of weights and measures, which really belonged to bygone ages, was a great impediment to our operations. He was sure the change proposed would have a beneficial effect on the growth of our industries. The change was inevitable, and should be carried out without delay, while as to the difficulties, Germany, split up as she was, had been able to overcome them in four years. The motion was seconded by Mr. J. Emerson Dowson, C.E., and after it had been supported by half-a-dozen speakers, was carried. A further resolution was passed to the effect that the Hon. William L. Wilson should be informed of the present position of the movement in this country for adopting the metric weights and measures, and that he be invited to use his influence to secure such legislation as may provide for the adoption of this system of weights and measures in the United States.

Central Electric Light Stations in Paris.—In *L'Industrie Electrique*, Mr. J. Laffargue gives some particulars respecting the central electric light stations in Paris. The Compagnie Continentale Edison has now three central stations—the Drout, Trudaine, and Palais Royal, as well as a St.-Georges sub-station. When the output is at its maximum the stations are coupled in parallel. The company has made every endeavour to improve the condition of the mains, which at first were very defective. Artificial ventilation is employed, and other improvements have been introduced. The Société Anonyme d'Eclairage et de Force par l'Electricité have continued their work without any important changes on the original installations, showing that the original scheme had been well considered and satisfactorily carried out. The Société Anonyme d'Eclairage du Secteur de la Place Clichy possess a central station which has been established under excellent conditions. Since 1892 there has been added to the plant two vertical steam-engines of 500 h.p. Great care is exercised in the supervision of the machinery. Minute precautions are taken in connection with the testing of the mains, and a portable laboratory is taken to all parts of the district so that the whole of the network is visited once a year. Visits are also made from time to time to inspect the installations of customers. The Compagnie Parisienne de l'Air Comprimé has ever since it started been undergoing a process of transformation. The district is now to be arranged for two central stations and three sub stations, the five-wire system being employed. The Société Anonyme du Secteur Champs-Elysées have the concession of a very wide district, mainly consisting of private houses and hotels, and the distribution has been more difficult than in central Paris. The company appear to have some difficulties in connection with the coupling of alternators in parallel. The Société Anonyme du Secteur de la Rive Gauche are one of the least advanced. Their central station at Ivry is still only a project, though the subject has long been under discussion. The Usine Municipale d'Electricité des Halles Centrales shows little alteration from its original arrangements, but four Desrozier dynamos and two batteries of accumulators have been added. On the whole, the central stations of Paris are in a satisfactory condition, and have got over their initial difficulties. The most delicate part of the work has been in connection with the laying of the mains, owing to the conditions imposed by the municipal authorities.

It was about half-past nine when, on looking towards the chair, the fingers of the toastmaster in the rear were observed to twitch nervously round a small mallet. Someone was heard to remark that an auction was about to take place, but by dint of expostulation the toastmaster was quietened down, and no bargains were made. Then, with a gentle tap, way was given to

The PRESIDENT, who in a few touching words proposed the toast of "Her Most Gracious Majesty the Queen." This having been duly honoured, the President put that of "Their Royal Highnesses the Prince and Princess of Wales, and other Members of the Royal Family," adding some appropriate words in reference to the cordial sentiments existing between those absent at the Russian Court and the Russian Royal family.

"Our Colonial Empire," coupled with the names of Sir Saul Samuel, K.C.M.G., C.B., agent-general for New South Wales, and Sir Malcolm Fraser, K.C.M.G., agent-general for Western Australia, was also proposed by the PRESIDENT.

Sir SAUL SAMUEL, in the course of his reply, caused some amusement by stating that by the aid of submarine telegraphs to the colonies we could send telegrams there to-day, a distance of 12 or 13 miles, and get a reply next morning. But the astonishment depicted on the surrounding countenances caused him to extend the distance to between 12,000 and 13,000 miles. As an instance of land work in the colonies, he mentioned that in the early days fencing wire was used for telegraphic purposes, wooden insulators covered with shellac being employed.

Sir MALCOLM FRASER, in acknowledging the debt Australia owed to the Institution of Electrical Engineers, went so far as to state that electricity was only in its embryonic stage. It was fortunate for him on that occasion that steam interests were subservient to those of electricity, or his observation that steam had had its day, and that the century would hardly last out before it was overcome by its rival—applied science of electricity—would hardly have been permitted to pass unchallenged.

A few seconds vanished before the ironical laughter passed away on the announcement by the toastmaster that Mr. Pearce would give the toast of "The Learned and Engineering Societies," coupled with the names of Dr. H. E. Armstrong, F.R.S. (president of the Chemical Society), and Sir Robert Rawlinson, K.C.B. (president of the Institution of Civil Engineers).

Mr. W. H. PREECE, F.R.S., who, whilst fully appreciating the joke, assumed a solemn countenance, said, lest there were any doubt as to the identity of the individual, that "I am the man." After an amusing story of the Irishman and the egg—the difficulty being either the killing of the man or the hatching inside him of a Cochin China chicken—the speaker said that the engineer was the man. The practical man of to-day, he continued, had not only alleviated, but removed disease; he at the same time utilised energy; he extended life, and, after all, he succeeded in answering in the most practically satisfactory way the question, "Is life worth living." The finger of the philosopher had pointed the way in which the practical man had to go.

Sir ROBERT RAWLINSON, who met with a similar misfortune to that attending Mr. Preece, he being at first announced as Dr. Armstrong, made some suitable remarks on behalf of civil engineering.

Digitized by Google

Dr. H. E. ARMSTRONG excited some interest by propounding the problem whether orange-peel or electricity was the greater danger to public safety. He did, however, not attempt a solution. A little shot was fired at the expense of electrical engineers, who were told that they were moving in too narrow a sphere, and that they were "slaves of the lamp"—no, of the dynamo. Whilst attention was largely being devoted to the dynamo and its uses in producing light and as a source of power, there were other uses for the electric current which were likely to be of enormous importance. For instance, on the chemical side there was its application in connection with bleaching operations, and in other directions, and there was no doubt that ere long all copper would be made by the aid of the electric current. The speaker suggested the widening of the sphere of operations on the part of electrical engineers in the great development that would take place, and in this they would be assisted by chemists. Unfortunately, they were greatly behind in those matters as compared with the Continent.

Dr. J. HOPKINSON, F.R.S., in proposing "Our Guests," united with the toast the names of the Right Hon. James Bryce, M.P. (President of the Board of Trade), and Lieutenant-General Sir Andrew Clarke, G.C.M.G., C.B. The speaker observed that part of the duties of the Board of Trade was to curb the aspirations of the electrical engineer. He suggested that the Mr. Bryce who wrote about the American commonwealth should confer with the Mr. Bryce who presided over the Board of Trade, and bring to his notice the fact that in America, where electrical engineers were far less trammelled than in this country, there were thousands of miles of electric tramways. Supposing that once in a way this greater freedom did result in the loss of a life or two, surely the Mr. Bryce who climbed Mount Ararat might think the loss compensated for by the increased facilities afforded to the public.

The Right Hon. JAMES BRYCE, M.P., amused his hearers by mentioning that there were three poets at the Board of Trade. As if to dispel any idea that this was detrimental to the Department, he stated that those three gentlemen were the most efficient on the staff. In paying a high tribute to the Institution of Electrical Engineers, he stated that the Board of Trade looked on the Institution as a reservoir of knowledge to go to whenever they were in any difficulty. Valuable service had been rendered in that way in connection with electric lighting. The Board of Trade had been able to do much to facilitate the progress of electrical engineering, especially by fixing those electrical standards which were adopted by the Chicago Conference, and which they hoped in a short time to see adopted by the leading Powers of Europe. He agreed with the proposer of the toast that the United States were ahead of us in electric lighting of cities, but he doubted whether they were so far advanced in the lighting of private houses, and the Department would soon have matters under consideration with regard to electric tramways and light railways which would, he hoped, bear fruit in no distant period. They were more tender of human life than their American kinsmen, and he thought they would agree with him that progress in electrical engineering would proceed more rapidly and meet with more popular favour if accompanied with safety, as at present, than if it were accompanied with such accidents as often occur in America. No pains were spared by the Board of Trade to facilitate the creation of new undertakings calculated to give employment, to add to the comfort of the public, and to develop commerce. Their work progressed faster than the politicians, for they were anxious to help one another and find out the truth, while the politician was engaged in efforts of an exactly opposite character. Any attempt to make progress in politics led to an immediate evolution of heat, while they provided light with as little heat as possible. He thought theirs was the more enviable lot, seeking the unseen and hidden truths of nature. They were engaged in bringing mankind into one chamber, and in trying to draw force from the wind and water, hoping thereby to turn the banks of mountain streams into homes of industry. It was impossible not to admire what they had done, and to look forward with pleasurable anticipation to what they hoped to do.

The concluding toast, proposed by Sir JOHN PENDER, M.P., was "The Institution of Electrical Engineers," which was suitably acknowledged by the PRESIDENT.

ON THE EFFECT OF MAGNETISATION UPON THE DIMENSIONS OF WIRES AND RINGS OF ANNEALED IRON.*

BY SHELFORD BIDWELL, M.A., LL.B., F.R.S.

In the year 1885 I submitted to the Royal Society the first of a series of papers † upon the changes produced by magnetisation in the dimensions of rods, etc., of iron and other magnetic metals. The chief, and perhaps the most interesting subject of the paper, was the observation that if the magnetising force were sufficiently increased, the extension which a magnetised iron rod at first underwent (as originally noticed by Joule)‡ was followed by contraction, the rod ultimately becoming shorter than when it was unmagnetised. The elongation was generally found to attain a maximum with a magnetising force of from 80 to 120 C.G.S. units, and to vanish with a force of 300 to 400, retraction occurring when still higher forces were applied.

From that date until quite recently no accounts of similar experiments by others workers have, so far as I know, been published. About the beginning of last year, however, it was stated in the scientific journals that M. Alphonse Berget had investigated the magnetic dilatation of iron in strong fields, and had found that the length of his bar was still increasing when the magnetic field had reached as high a value as 540 units, beyond which point the experiment was not carried.

On reference to the original paper in the *Comptes Rendus*,§ it appeared that the experiment was made with a cylindrical bar measuring 5·2cm. by 1·95cm., its length being less than three times its diameter. The actual magnetising force must therefore have been enormously less than that due to the coil itself, and it is very improbable that it ever reached the value at which the iron or the greater portion of it (for the magnetisation must have been far from uniform) would attain its maximum extension.

The *Philosophical Magazine* of December, 1893, contains an account of some experiments by Mr. Sydney Lochner, made, as he states, with the express object of determining whether M. Berget's results or my own were correct. Using a thin iron rod, he obtained a curve very closely resembling those published by myself; but, as might have been expected, he found that a short thick rod, like that of M. Berget, gave no decided indication of having passed a maximum extension within the limits of the magnetising force that he employed.

A paper of great interest on "Hysteresis Attending the Change of Length by Magnetisation in Nickel and Iron," by Mr. H. Nagaoka, published in the *Philosophical Magazine* for last January, also incidentally confirms my observations.

In subsequent papers I have shown how the elongations and retractions were modified by tension, and by the passage of electric currents through the specimens under examination; and in the present communication I propose to deal with the somewhat unexpected effects which were produced by carefully annealing the iron before using it.

Upon this point, Joule's observations are as follows: "On inspecting the tables, it will be remarked that the elongation is, for the same magnetic intensity, greater in proportion to the softness of the metal. It is greatest of all in the well annealed iron bars, and least in the hardened."‖

The current belief, in which till quite recently I myself shared, is in accord with this statement. It appears, however, as will be shown, that it represents the reverse of the truth. Joule's conclusion with regard to iron seems to have been based entirely upon the results of a single experiment with an unannealed bar, and he may possibly

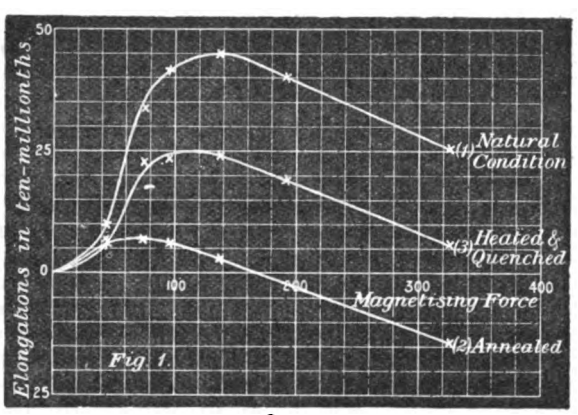
have been mistaken in supposing that it consisted of the same quality of iron as the annealed bars which he had used before.

My own experiments, the results of which are given in Table I. and Fig. 1, were made with a piece of iron wire 10·6cm. in effective length and 0·265cm. in diameter. The curve marked (1) shows the behaviour of the iron in the condition in which it was bought. Its length increased rapidly with the magnetising force, the maximum increment which was obtained in a field (due to the coil) of about 140 units being as much as 45 ten-millionths of the length of the wire. The same wire was then carefully annealed, and the experiment repeated, with the results indicated in curve (2). It will be seen that the maximum increment had fallen from 45 to about eight ten-millionths—less than one-fifth of its former value—and was reached with a force of about 60 units. Finally, the wire was raised to a bright red heat in a blow-pipe flame, and dropped into cold water, its subsequent performance being as indicated in curve (3). This last operation was found to have raised the maximum elongation from eight to 25 ten-millionths, while the corresponding magnetising force had increased from 60 to about 110 units.

TABLE I.

Magnetising force, C.G.S. units.	Elongations in ten-millionths of length. Iron as bought. (1).	Annealed. (2).	Made red hot and quenched (3).
43	10	7·0	6
74	34	7 0	23
96	42	6·0	24
138	45	3·5	24
192	40	− 1·2	19
324	25	−17 0	6



Other experiments gave results of a similar character, and many attempts were made to obtain an annealed wire which would not be lengthened at all by magnetisation, but begin to contract from the first, like nickle and cobalt. But I never succeeded in bringing a wire into such a condition that its maximum elongation was less than seven or eight ten-millionths.

Though I failed with straight wires, however, I was perfectly successful with an iron ring.

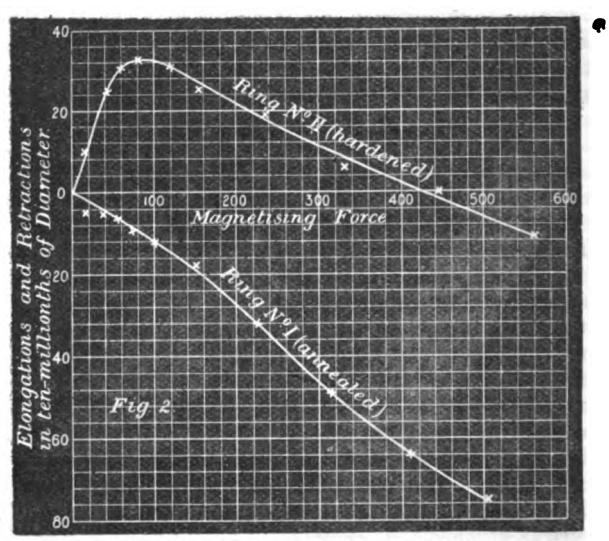
I have in a former paper given an account of some experiments made with rings.* The changes in the diameter of a ring were found to be of just the same character as those observed in straight rods. With a continuously increasing magnetising force, the diameter first increased in length, and after passing a maximum, ultimately became shorter than at starting.

In those experiments three different rings were employed, not one of which had been annealed before being used; I therefore had a new ring made of good soft iron, and very thoroughly annealed. It was afterwards fitted with a boxwood jacket, around which 515 turns of insulated wire were wound in the usual way. With this ring it was found that the smallest currents which caused any effect at all produced contraction. There was no indication of the smallest preliminary extension.

The results of an experiment with the ring (which I shall call Ring I.) are given in Table II, and in the lower curve of Fig. 2. The latter bears a close resemblance to the earlier portion of the curve given by a rod of cobalt. The greatest retraction reached was nearly 75 ten-millionths (exceeding any that has been ever before obtained with iron), and from the appearance of the curve there is reason to believe that this was still far from its limiting value, but the heating effect of the magnetising current made it impossible to carry the experiment further.

TABLE II.

Ring II. (annealed) Magnetising force, C.G.S. units.	Elongations in ten-millionths of length.	Ring I. (hardened) Magnetising force, C.G.S. units.	Elongations in ten-millionths of length.
15	− 4·5	15	10
39	− 5·6	42	25
56	− 6 2	61	31
73	− 9	81	33
101	−12	119	31
152	18	155	25
226	−32	239	19
312	−49	328	6
410	−64	445	0
506	−75	560	- 11



I at first contemplated unwinding the wire, hardening the iron, and repeating the experiment with the same ring; but felt unwilling to run the risk of spoiling so remarkable a specimen which it might turn out to be difficult or impossible to replace. I therefore had another ring made of iron from the same parcel, and believed to have been cut from the same bar as the first. As, however, there was some doubt about this latter point, I thought it better in the first instance to anneal the new ring, and test it with a few turns of wire wound upon it. Its behaviour was found not to differ materially from that of Ring I. A very small elongation—too small to be measurable—was, however, observed with a magnetising force of only three C.G.S. units, contraction beginning when the force was increased beyond this value. The ring was then made red hot, and plunged into cold water, with the object of hardening it, after which operation it was replaced in its boxwood jacket and wound with 473 convolutions of wire.

This ring, called Ring II, was now found to give the same results as the old unannealed rings and straight wires. As appears in Table II. and Fig. 2, it attained its maximum elongation of about 33 ten-millionths in a field of 80, its original length was recovered in a field of about 440, and a retraction of 11 ten-millionths occurred in a field of 560.

It appears, therefore, that as regards magnetic changes of dimensions, an iron rod or ring is affected by annealing in very nearly the same manner as by tensile stress,* a result which would hardly have been anticipated.†

* The Philosophical Society's *Transactions*, 179, A, p. 205. A ring is prepared for the experiment in the following manner: Short brass rods are attached to it at opposite ends of a diameter, forming prolongations, which serve to transmit the effect of changes in the length of the diameter to the measuring instrument. The ring is then covered with a loosely-fitting boxwood jacket, also ring-shaped, and through holes in this the two brass rods protrude. The magnetising coil is wound directly upon the wooden ring, the object of the latter being to protect the iron from the heat generated when a current is passing through the coil.

* Royal Society's *Proceedings*, vol. 7 (1890), p. 469.

† The less so since the length of an iron rod seems to be diminished by annealing. A piece of iron wire 100mm. long, cut from the same hank as that used in the experiments, was heated in

Notes Regarding Details.

The apparatus and methods of experiment were the same as those fully described in the Philosophical Society's *Transactions*, vol. 179, A, pp. 218, 224, the instrument being arranged so as to have a magnifying power of 43,745.

The height of each little square in Fig. 2 corresponds to a length of about one-millionth of an inch (0·00000088in. for Ring I, and 0·00000103in. for Ring II).

The wires and rings were demagnetised by reversals before every single observation. For a description and diagram of the demagnetising apparatus, see *loc. cit.*, p. 207.

The dimensions of the iron rings and their boxwood jackets were as follows:

	Ring I.	Ring II.
Rings—External diameter	6·9cm.	6·1cm.
Width	2·9 ,,	3·0 ,,
Thickness	0·4 ,,	0·35 ,,
Mean radius	3·25 ,,	2·82 ,,
Boxwood jackets—External diameter	7·7 ,,	6·9 ,,
Width	3·7 ,,	3·8 ,,
Thickness	1·3 ,,	1·15 ,,
Convolutions	515	473
Gauge of wire	0·91mm.	0·91mm.

The rings were formed from rectangular bars with welded joints, and were turned in the lathe to the above dimensions.

The magnetic fields were calculated from the formula $H = 2ni/r$, where n is the number of convolutions, i the C.G.S. current, and r the mean radius.

The current was derived from a battery of 27 storage cells used for lighting the house.

ECONOMICAL WORKING OF ARC LAMPS.

In arc light installations, as is well known, the cost of carbons forms a considerable part of the working expenses, which it is desirable to reduce. With a view to overcome this disadvantage Messrs. Hardtmuth and Co., of Vienna, have devised an apparatus for the purpose of diminishing the consumption of the carbons by surrounding the upper electrode with a protecting mantle. As our readers are aware, there is formed in the upper carbon during the period of lighting, not only a crater, but the end points conically towards the edges of the crater. The cause of this lateral consumption of the carbon is to be found in the circumstance that the current of air produced through the points of the arc spreads to the side surface of the carbon upwards, and thus renders its consumption possible. If one succeeds in preventing the free passage of the air to the upper or positive carbon, the cause of the useless consumption of the outer carbon surface in the production of light is removed, and the duration of the carbons is correspondingly prolonged. This arrangement, according to the *Elektrotechnische Zeitschrift*, constitutes the principle of the apparatus devised by the firm mentioned, who term it a "lasting burner."

The appliance consists, as will be seen from the illustration, of a mantle surrounding the upper carbon carried in a bow and frame as shown. The frame is provided at its lower horizontal part with a leading-in ring, which, by means of three small platinum cramps, is arranged on the conical end of the negative carbon, and in such a manner that as the latter is used it falls with it. The vertical rods of the small frame are provided with male and female screws, and are insulated from the upper horizontal bow. Moreover, the upper part of the metallic protecting mantle is surrounded by a tube of insulating material, through which the carbon can freely pass. The lower and distant part of the protecting mantle is enclosed in a fireproof mantle, and the dimensions are so chosen that a circular air passage remains between this mantle and the outer surface of the carbon rod. By the insertion of the screws, the distance between the protecting mantle and the leading in ring is so regulated that when the lamp is alight the lower end of the positive carbon lies at the same height as the under edge of the protecting mantle. The end of the carbon is therefore almost completely protected from air currents.

Experiments with this apparatus have been made in the Vienna Technological Trade Museum (Versuchsanstalt für Elektrotechnik) to ascertain whether the fact of adopting the "lasting burner" affected the lighting power of the lamp, and what the saving in carbons amounted to. For this purpose the same lamp (having carbons 11mm. and 16mm.) was tried both with the appliance and without it, photometric tests being taken. It was found that the introduction of the apparatus did not essentially affect the lighting power of the arc lamp. As far as the consumption of carbons is concerned, the following figures from the tests mentioned show the use per hour:

Consumption in millimetres.	Upper carbon.	Lower carbon.
Lamp not fitted with "lasting burner"	14·1	15·5
Lamp equipped with "lasting burner"	4·9	10·0

NON-SYNCHRONOUS ALTERNATING-CURRENT MOTOR FOR HIGH PRESSURE.

In installations for the distribution of electrical energy for power purposes at high pressure on a large scale, the use of small motors at low pressure fed from transformers is generally recommended, whilst large motors are directly constructed for the high pressure on the line. Apart from the important reduction in the cost of installation incidental to the latter, the dispensing with the employment of large converters essentially simplifies the installation and renders the working safer, of course assuming that that part of the motor carrying the high-pressure winding is at rest.

In discussing this subject in the *Elektrotechnische Zeitschrift*, Mr. Emil Kolben, of Oerlikon, says that, notwithstanding the inconvenience of a separate exciter, synchronous motors similar to the generators have hitherto been recommended for use as large alternating-current motors. This is due, on the one hand, to the fact that a proper method of constructing large non-synchronous motors was not hitherto known; and on the other, because of the considerable current strength at no load, which was inconveniently made perceptible through the load on the line and the generators.

This disadvantage, the author states, has, however, now been met by such careful design and solid construction as to allow of a reduction to a minimum of the play between the fixed and rotating parts. This has been accomplished by a clever arrangement of the winding, which only admits of slight distribution of induction, but especially by correctly dimensioning the individual parts. By this means we obtain for the working of a motor at high efficiency down to one-tenth load, the capability of overloading, insensibility to changes in pressure and even changes in speed of the primary machine, and the advantage of not having to use a direct-current exciter. It is correct that the factor of performance is not so favourable with a non-synchronous motor as with one of the synchronous type, although this difference almost disappears at full load, which, indeed, is only proportional to the maximum fall of the line and of the generator.

With a view to show the difference between the two kinds of motors, the results of a series of tests with an 80-h.p. synchronous motor and a 100-h.p. non-synchronous

a Bunsen flame and slowly cooled. It was found to have contracted 0·07mm.—*i.e.*, 0·07 per cent. It was then heated in the blow-pipe flame and dropped into cold water. This produced an elongation of about 0·02mm., leaving the wire 0·03mm. shorter than it was originally. These measurements were made with a rough apparatus extemporised for the purpose, and I do not attach much importance to the quantitative results, though there can be little doubt that they are qualitatively correct.

Digitized by Google

motor are graphically represented in Figs. 1 and 2. The former is installed in a corn mill and the latter in a spinning mill. The synchronous motor is of the Kapp type, with a flat disc armature, constructed by the Maschinenfabrik Oerlikon, of Oerlikon, near Zurich. It is wound for 2,200 volts, with its shaft direct coupled to its exciter. The E.M.F. curve is almost exactly a sine curve. The non-synchronous motor shown in Fig. 3 is an 18-pole high-pressure three-phase motor built by the same firm for 1,730 volts pressure at 50 periods per second, and arranged for rope-driving at the low speed of 320 revolutions a minute.

It will be seen from the curves that the factor of performance of the synchronous motor is more favourable for all loads than that of the non-synchronous motor, although the difference at full load is small, being 0·94, as compared with 0·86. This difference, for instance, with a loss on the line of 5 per cent. would scarcely bring about ½ per cent. additional drop in the conductor. On the other hand, the efficiency of the non-synchronous motor is higher at all loads; its curve is such as those of a good transformer. It amounts at full load to 91 per cent., as compared with 86 per cent. of the synchronous motor. The total exciting energy, including losses in the exciter, are comprised in this especially at small loads, where it strongly reduces the efficiency.

ELECTRIC LIGHTING AND TRACTION IN SPAIN.

Some time ago a correspondent in Bilbao sent to *L'Electricien* a communication (which we abstracted at the time) referring to electrical matters in Spain. The same correspondent now writes to that journal that development continues to take place. At present, he states, the Allgemeine Elektricitäts-Gesellschaft, of Berlin, does the major portion of the work; the other firms, including the Oerlikon Maschinenfabrik, Messrs. Schuckert and Co., and Messrs. Siemens and Halske, only dealing generally with small installations. An exception is, however, to be found in the case of Messrs. Schuckert, who have equipped a central station at Baracaldo, near Bilbao, with plant to the extent of 600 h.p. for the supply of alternating current to some twelve villages situated on the left bank of the Nervion. The Allgemeine Company have formed, with the assistance of Seville commercial firms, a company with a capital of £80,000 for the electric lighting of Seville. The central station will comprise three groups of 400 h.p. each, and as the Allgemeine Company are now making 120-volt lamps, it will be possible to arrange the arc lamps three in series for public lighting. The same company have acquired the station erected at Barcelona by the Sociedad Espanola de Electricidad, having 8,000 lamps connected, and it has now been resolved to establish a new station, comprising three groups of 1,000 h.p., at a cost of £240,000. It is intended to start this station in a year, when the old works will be shut down. Apart from lighting operations, the Allgemeine Company are pushing ahead with electric traction. One instance of this is to be found at Bilbao, where the company have entered into a contract for the conversion of the horse-car line from Bilbao to Santurce to an electric tramway. It is anticipated that the work, which is being hurried on, will be completed so that the line may be opened next June. The tramway, which is about nine miles in length, runs parallel with the Portugalette railway, and it is expected that it will prove a formidable competitor to the latter, which annually carries 2,500,000 passengers. The line will be on the overhead trolley system, and will be equipped with 12 cars fitted each with two 25-h.p. motors, and capable of hauling trailers at a speed of 12 miles an hour. The generating station will be erected at Luchana, and will contain plant to the extent of 330 h.p. Other electric traction schemes are under consideration.

THE SURPLUS AND DEFICIT THEORY OF ELECTRICITY.

BY W. PERREN MAYCOCK, M.I.E.E.

(Concluded from page 577.)

There is not much transference of electricity, however, owing to the small capacity of the ends of the E.M.F. circuit. The coating of the condenser will therefore only receive a small charge; the deficit on the right-hand coating will, of course, be equal to the expelled surplus, and both of these will be slightly less than the influencing surplus on the other coating. From what was said in section (*b*), it is clear that both coatings of the condenser are at a + potential; but there will be a slight P.D. between them, due to the preponderance of the influencing charge over the influenced charges. This may be verified by means of the discharging tongs, D, the spark obtained (the length of which is proportional to the P.D. between the coatings) being in this case only just perceptible. The influence machine should be disconnected from the condenser (while it is rotating at its normal speed), before making the above experiment.

In the next case (Fig. 11 VI.), the right-hand coating of the condenser is connected with earth. This allows the surplus thereon to flow to earth and a greater deficit to be influenced on the inner side. This increases the capacity of the left-hand coating, enabling it to receive a larger charge. As before, the greatest P.D. exists between the left-hand terminal of the machine and the left-hand coating of the condenser. Now, though the right-hand end of the E.M.F. circuit has been increased in capacity, the capacity of the left-hand end—*i.e.*, of the terminal—is, as in the first case, very small; and when we consider it is from this that electricity is being "pumped," it is easy to understand that the ultimate P.D. between the ends of the circuit is reached without the transference of much electricity, the potential at the − end falling more rapidly than it increases at the + end. The quantity of electricity displaced will, however, be greater than in the first case, owing to the increased capacity of the right-hand end of the circuit. Now with regard to the condenser; as we have already seen, the + charge on the left-hand coating is greater than before; there is a nearly corresponding deficit on the opposite coating, and the repelled surface has gone to earth. Disconnect the machine while running, and then the earth wire. The right-hand coating is now clearly at earth's potential, since it has just been disconnected therefrom; while the left-hand coating is at a slight + potential, nearly all its charge being bound by the opposite deficit. There is, however, a considerable difference of potentials between the coatings, and the spark obtained with the discharging tongs will be much longer than in the previous case.

In the last example (Fig. 11 VII.) the − terminal of the influence machine is connected with earth, through which it is in connection with the condenser's right-hand coating, or it may be connected directly thereto. The machine on being rotated "pumps" electricity from one coating into the other. The capacity of the −end of the circuit being very great, the influencing charge will be large to start with; the deficit on the opposite side (partly due to influence, but principally due to the fact that electricity is being "pumped" away from there) will react on and increase this; the capacity of both coatings will be very much increased, and a considerable quantity of electricity will be displaced before the P.D. between the coatings reaches its maximum, which will be when it is about equal to the E.M.F. of the machine. On disconnecting the condenser and discharging it, a long and thick spark will be obtained, showing that the P.D. and the quantity of electricity displaced is greater than in either of the two previous cases. The discharging of the condenser should be done directly after disconnecting it from the machine, as there is always a certain amount of leakage taking place over the surface and edges of the glass dielectric.

(*l*) *The Action of Points.*—If a charged body has a projecting point upon it, the charge will be slowly dissipated into the air at the point. If, facing the point, there is another conductor, the discharge will be more rapid, and will be still more rapid if the conductor facing the point is earth connected. A conductor may also be discharged by presenting an earth-connected point to it.

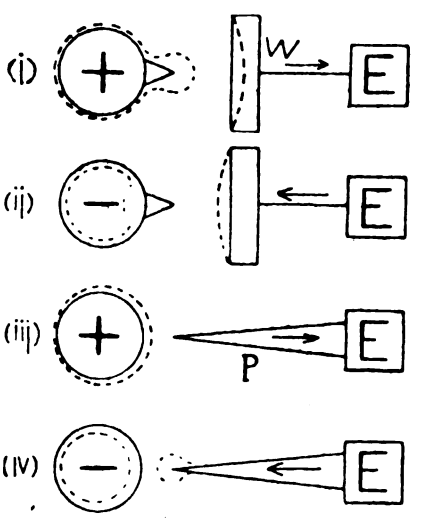

FIG. 12.

In Fig. 12 I., + is a +ly charged body, and W an earth-connected conductor, such as the wall of a room. We will first consider the case in which there is no conductor opposite the point. The density on the charged body is approximately indicated by the dotted line; at the point it is very great, so great, in fact, that the air and dust particles immediately around the point become +ly charged also; these then fly off from the point, and others take their place, become charged in a similar manner, and are repelled. As these electrified particles have no neighbouring body to impart their charge to, the discharge at the point is not very energetic. Now, let us suppose the earth-connected conductor, W, to be opposite the point. The presence of the charged body will influence a deficit on the side of W facing it. To this region the +ly electrified particles will be attracted, they will give up their charges to W, and will then move to one side to make room for other charged particles. There is thus a continual "wind" coming off from the point, which may be felt by the hand if the point is on a highly-charged conductor, such as the terminal of an influence machine.

In Fig. 12 II., the case of a −ly charged body is considered, first of all without an opposing conducting surface. The − density round the point is so great that the neighbouring particles of air, dust, etc., which, like every other body (conductor or insulator), may be supposed to have a certain

Digitized by Google

quantity of electricity upon them, have part of this abstracted to help fill up the deficit on the charged body, and being then themselves in a state of deficit, are repelled from the former, their place being taken by others which are likewise acted upon. The deficit in the charged conductor is thus gradually filled up with electricity abstracted from neighbouring air particles. When there is a conducting surface facing the point, a + density is influenced thereon. To this part the −ly charged particles are attracted, and having had their deficits filled up, move on one side to make way for others.

Next we have the case of a +ly charged body with an earth-connected point presented to it. A − density will be influenced at the point, and the particles around, in the same manner as was explained just now, will have electricity abstracted from them, and being −ly charged will be attracted to the charge-ball +, and have their deficits filled up from it. In other words, a stream of −ly charged air particles will be projected at the ball, and gradually rob it of its charge.

Lastly, in Fig. 12 IV. we have a body with a deficit. A surplus consequently is attracted to the point, and the density becoming great, a stream of +ly charged particles is projected at the ball, to which they deliver their small charges, this going on until the ball is practically discharged.

Conclusion.—This article might be indefinitely continued with explanations of other elementary and well-known experiments in electrostatics, etc., based upon the simple theory which was enunciated in the opening paragraphs. Enough has been said, however, to enable the student to do this for himself, and he will find that many results which before appeared vague and difficult of explanation, will be clearly accounted for in the light of the "surplus and deficit" theory. At the same time it should be remembered that this theory is intended only as a practical help to students, and does not pretend to any scientific importance.

UTILISATION OF BLAST-FURNACE GASES.

An article dealing with the utilisation of blast-furnace gases for industrial purposes was published in the last issue of the *Iron and Coal Trades' Review*. The following is abstracted from the article in question:

Of late years a good deal has been done in the way of making provision for leading off the furnace gases for the raising of steam or other calorific purposes, and in all well-regulated works no other fuel is now employed for boiler purposes. But it has been felt and acknowledged that there was still a great waste of gas or calorific power that should be capable of utilisation, and advanced metallurgists have looked hopefully forward to the day when the waste might be expected to cease.

Among the many projects applied or suggested for this purpose we learn that Mr. B. H. Thwaite has recently been undertaking researches which have demonstrated to his satisfaction that a blast furnace of only 300 tons weekly capacity of iron output can produce sufficient power gas to drive internal-combustion or gas engines equal in the sum of power actually available to from 1,600 h.p. to 1,800 h.p. per hour. He has calculated that this large amount of power can be electrically transmitted, with a loss of not more than 15 to 20 per cent., within a 15-mile radius from the furnace to villages, towns, or other centres of manufacturing industry that either can or are likely to be able to absorb such power.

In the system for the utilisation of the gases of blast furnaces designed by Mr. Thwaite the gas is led off to an internal-combustion thermodynamic motor or gas-engine. Where a furnace is worked with 4lb. to 5lb. of blast it is calculated that three times the power that is given by the same expenditure of power for blowing purposes can be generated by the employment of a high-speed gas-motor air-blower to develop 15lb. of air heat pressure, while the output of the furnaces may be largely increased. Mr. Thwaite has made a tabular estimate of the calorific value, for the different purposes to which he proposes to apply it, of the gas generated in blast-furnace working, and the results are really very startling. By substituting gas motors, actuated by blast-furnace gas, for the present steam-power machinery employed in iron and steel works, Mr. Thwaite finds that a large economy can be effected. And in such a case the distance of the mills to be driven from the furnaces that supply the means of driving them is, within certain tolerably wide limits, a matter of comparatively little importance. If the furnaces are not more than five miles distant from the mills to which the power is to be applied, the energy lost in transmission is not likely to be great, because, with high-pressure transmission with transformers, such energy can be transmitted for a distance of quite 100 miles with not more than 30 per cent. loss of energy. But the utilisation of such power is not by any means limited to mills alone. It can also be utilised with advantage for colliery underground work, for pumping, drilling, and hauling; for general lighting and power purposes within a few miles of the furnaces, and for other requirements. It is not at all unlikely that power so supplied would make it possible to sell gas for lighting purposes at much less than any price at which it has hitherto been supplied, while yielding to the hitherto greatly distressed maker of pig iron a residual fund that might ultimately realise the dream of more than one enthusiast on behalf of the latent possibilities of the blast furnace—namely, that of making the manufacture of pig iron merely a by-product.

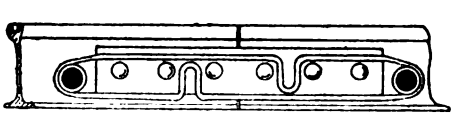
RICHARDSON'S INVERTED ARC LAMP.

In our issue of October 27, 1893, was published a paper "On the Artificial Lighting of Workshops," reference being particularly made to experiments with inverted arc lamps. In this connection a circular has reached us from Mr. A. W. Richardson, of Patricroft, near Manchester, concerning his inverted arc lamp. This lamp, which varies considerably from most others, is a differential focussing brake wheel lamp, of which the following is a brief description. A large wheel gears into two racks, in which a pinion gears, the brake wheel being on

the same arbor. The brake arrangement is attached to a locking lever, at each end of which are fixed the cores of the main and shunt coils of a large area, which allow of a most sensitive and continuous feed. Mr. Richardson states that by taking a room, 24ft. long by 24ft. broad and 12ft. high, having a whitewashed ceiling, and equipping it with a 12-ampere inverted arc lamp placed in the centre, the light is diffused everywhere. The diffusion, he says, is so perfect that men can carry out minute work at benches placed round the room with their backs to the light. This advantage is at once apparent with regard to machinery, as not only is the portion the man may be manipulating plainly visible, but the whole of the machine is equally lighted.

TRAMWAY RAIL BOND.

In the annexed illustration is shown a bond for tramway rails devised by Mr. F. Foley Robinson, A.M.I.C.E., of 48, Elopeth-road, Lavender Hill, S.W., and exhibited at the meeting yesterday (Thursday) evening of the Institution of Electrical Engineers. The terminals consist of short metal tubes



expanded into the webs of the rails in the manner usually employed by boilermakers to secure tubes in tube plates. It is claimed for this bond that it is cheap, as ordinary wrought-iron tube may be used sawn into short lengths and oxide removed by grinding or otherwise, no turning or expensive machinery being thus required, and that the bond affords a large and efficient contact area, the surfaces of holes and tubes being quite bright.

Storage Battery Litigation.—The following communication reached us at the moment of going to press, this referring to a paragraph given in our Business Notes: "We are informed that the Chloride Electrical Storage Syndicate, Messrs. Mather and Platt, Limited, and Dr. John Hopkinson contend that they are fully justified in making and using these [chloride] cells, and that they intend to offer a most strenuous resistance to the claims made on them. We also state that the Chloride Electrical Storage Syndicate are prepared to indemnify all persons who have purchased batteries from them, or who may do so."

INSTITUTION OF ELECTRICAL ENGINEERS, Nov. 22.

MR. ALEX. SIEMENS (President) in the chair.

At last night's meeting of the Institution the following candidates were balloted for:

Member.—Sir Benjamin Baker, K.C.M.G., F.R.S., 3, Kensington-gate, W.

Associates.—Charles Edwards Atkinson, care of Messrs. Strode and Co., 188, Piccadilly, W.; William Brown, care of Messrs. Siemens Bros. and Co., Woolwich; Herbert Ade Clark, 120, Ruskin-road, Crewe; C. J. Evans, 16, Castelnau-villas, Barnes, S.W.; Arthur H. Gibson, Bryanston, Blandford, Dorset; Ernest Mercer, 137, Stonefield-road, Hastings; John Patrick Mulholland, Eastern Telegraph Company, Gibraltar; Henry Stooke, 19 Room, War Office, Pall Mall, S.W.; Frederic G. Twemlow, 132, Bury New-road, Manchester; Charles Selby Whitehead, 29, Glazbury-road, West Kensington.

Students.—Arthur Verden Anderson, Faraday House, Charing Cross-road, W.C.; Ernest R. Cook, 29, Highbury-hill, N.; Francis Edward Davies, 51, Tregunter-road, South Kensington; Sydney Edward Thacker Ewing, Faraday House, Charing Cross-road, W.C.; David J. Gadsby, 34, Hamlet-road, Chelmsford; Charles D. Le Maistre, Central Institution, Exhibition-road; Charles Henry Marshall, Tileworth, Silverhill, St. Leonards-on-Sea; Arthur Du Pasquier, 28, Emperor's-gate, South Kensington; George W. D. Ricks, 8, Uxbridge-road, Surbiton; Robert Johnstone Scott, Faraday House, Charing Cross-road, W.C.; Benjamin Thomas Squibb, 176, Blackfriars-road, S.E; John Walton Ward, 43, Rutland-road, Ilford, Essex; Edmund Basil Wedmore, 11, Oakland-road, Bristol.

The following paper was then read on

ELECTRICAL STEEP-GRADE TRACTION IN EUROPE.

BY C. S. DU RICHE PRELLER, M.A., PH.D., A.M.I.C.E., MEMBER.

INTRODUCTION.

The rapid growth of electrical traction in Europe, wherever local conditions and reasonable official regulations are conducive to its adoption, is evidenced by the fact that within the last few years it has also been extensively applied, and is in course of further application, on steep-grade or mountain railways properly speaking—that is, on lines which have not only occasional steep-grade sections, such as occur, for instance, on many electrical tramways, but continuous gradients varying from 5 to 25 and upwards of 60 per cent. (1 in 20, 1 in 4, and 1 in 1·6 respectively), and which connect either the base and summit of a given declivity, or different districts separated by a mountain range. It will, therefore, not be inopportune if I place before the Institution a short synopsis of what has been already done in Europe in that branch of electrical engineering, together with certain conclusions and proposals founded on my own experience. Leaving aside for the present, as being more suitable for separate treatment, the question of heavy—viz., 50 to 100 ton—electrical locomotives for trunk railways, the working of steep grades by electricity may be considered under two heads: (1) by cable traction, and (2) by motor cars or locomotives with fixed conductors.

CABLE TRACTION.

Up to a recent period, steep-grade cable railways in various parts of the globe, but notably in Switzerland and in the Alps generally, where they alone exceed 20 in number, have been constructed for being worked either by component of gravity with water ballast in conjunction, on some lines, with a second or compensation cable, or in some cases by fixed hydraulic, gas, or steam motors. The principal disadvantage common to all lines worked by component of gravity consists in the excessive additional dead load due to the water ballast, which entails not only a great deal of additional brake power *per se*, but a variety of complicated safety brakes, involving very careful manipulation; while the three systems of fixed motors are either uneconomical, or unwieldy and obsolete. The superior advantages of cable traction by electrical motors, as compared with all the other systems referred to, have been attested by three lines in Switzerland, all of which have been constructed within the last four or five years—to wit, the Burgenstock, on the Lake of Lucerne; the Monte Salvatore, on the Lake of Lugano; and the Stanserhorn, near the Lake of Lucerne, which last named was opened for traffice only last year. It is not the purpose of this paper to give a detailed description of these lines; suffice it to point out their salient, and more especially their electrical features.

(*a*) *Burgenstock.*—The summit level of this line is 2,884ft. above the sea, the total rise being 1,443ft. in a little over over 1,000 yards, the minimum grade 32, and the maximum 58 per cent. Electric motive power for working the cable and cars is obtained by high-tension (1,600 volt) transmission from a hydro-electric power station 2·5 miles distant, the output of the two series-coupled direct-current Thury dynamos, driven by a high-pressure turbine, being 40 kilowatts, or 60 h.p. Two corresponding series-coupled motors at the summit of the cable railway drive the cable winding drum through belt, countershaft, and bevel gearing; the total reduction being 700 to 5 revolutions, or 140 to 1, corresponding to the regulation car speed of about three miles per hour. The speed is regulated from the motor station, and not by the driver, except in case of emergency.

(*b*) *Monte Salvatore.*—This line has a summit level of 2,900ft., the rise being 2,000ft. in a length of 1·2 mile, the initial grade at the base 17, and the maximum at the summit 60 per cent. The motor station is situated midway up the incline, and the power is derived by a 2,000-volt transmission from a large hydro-electric 1,500-h.p. power station five miles distant. The output of the Oerlikon (Brown) direct-current generator, driven by a high-pressure turbine, being 60 kilowatts. The correspond ing motor on the line drives the cars and cable in precisely the same way as on the preceding line, except that the Salvatore incline is worked in two sections.

(*c*) *Stanserhorn.*—This line ascends an altitude of no less than 6,200ft. above sea-level, and has a total rise of 4,570ft. in a length of 2·5 miles, worked in three sections, having maximum gradients of 30, 60, and 62 per cent. respectively. The requisite power per car is 40 h.p., and a motor station is placed at the summit of each section. The three Thury motors actuate the winding drums as before described, and are fed from the same power station as the Burgenstock line, but by a separate high-tension (2,000-volt) transmission 2·5 miles in length. The total efficiency on this, as on the other lines, is about 60 per cent.

(*d*) *Conclusions.*—The three lines of which I have given a necessarily very incomplete *résumé* mark a conspicuous advance in cable traction. As compared with haulage by the other systems referred to, they show a saving in car weight of no less than 50 per cent., the full car load with 36 passengers being in the former case 12 to 15 tons, and on the electrically-worked lines only six to seven tons. Again, the average cost of construction of the Swiss cable railways worked on the older systems is no less than £41,000 per mile, whilst that of the electrical lines is only £24,000 per mile, or 40 per cent. less. Similarly, the working expenses on the older lines vary, with one or two exceptions, between 60 and 80 per cent., whereas the electrical lines are worked at 45 per cent. of the receipts. These three lines also show a remarkable development due to electrical traction *per se*, inasmuch as, apart from the unprecedented grades, up to 62 per cent., or 1 in 1·6, the length of the incline has been gradually increased from 1,000 to 2,200 and 4,500 yards, which, having regard to the mechanical work performed on the grades, is equivalent to 14, 20, and 44 miles respectively on the straight and level. And, lastly, the superior safety and smoothness of electrical working attested by the Burgenstock and Salvatore lines, has made it possible to dispense on the Stanserhorn incline with the rack used as a safety factor on its two predecessors; so that on Stanserhorn electrical traction has achieved the feat of scaling Alpine altitudes which it was hitherto believed could only be reached by rack railways worked with special steam locomotives, such as those used on the neighbouring mountain Pilatus, at more than double the cost per train mile.

TRACTION BY MOTOR CARS OR LOCOMOTIVES WITH FIXED CONDUCTORS.

The first steep-grade railway worked by electrical traction with fixed conductors in Europe was the Florence and Fiesole line, opened in 1891. It was in succession followed by the Murren mountain railway, in Switzerland, opposite the Jungfrau; by the Mont Salève line, in Savoy, near Geneva; by the Genoa and then by the Zurich steep-grade road railways; and quite recently by a similar line at Barmen, in Rhenish Prussia. Of these lines, those of Florence, Murren, Genoa, and Zurich have continuous grades of 8, 5, 7, and 6 per cent. respectively, and are worked as simple adhesion lines, with overhead contact wires, and return circuit by the electrically bonded rails; while the Salève and Barmen lines having continuous inclines of 25 and 18 per cent., or 1 in 4 and 1 in 6 respectively, are worked with the aid of a rack, and the former has an outside conductor rail in the shape of an inverted ordinary flange rail, while the latter has overhead contact. The Murren line is the only one worked with electrical locomotives; all the others are worked by single-motor cars.

(*a*) At Florence the power station, situated at the foot of the incline, comprises three Tosi boilers, three Oerlikon vertical compound 90-h.p. engines, and three belt-driven Edison bipolar dynamos with a total effective power of 245 h.p., equal to 93 per cent. efficiency. The 12 motor cars are each fitted with two 20-h.p. spring-suspended and series-coupled Sprague-Edison motors, the original ones having double-reduction, the more recent ones single-reduction spur gearing. The contact is by trolley wheel and pole, and the total efficiency of the system is 66 per cent.

(*b*) On the Murren railway, whose altitute is 5,300ft. above sea-level, power is generated by a high-pressure turbine, which drives a direct-coupled Oerlikon (Brown) bipolar dynamo of 120 h.p. The power station is situated about midway of the line, the power being derived from the torrent of the celebrated Staubbach Fall. The four locomotives weigh 7·5 tons each, and carry two 30-h.p. single-reduction spur-geared motors; the

Digitized by Google

tractive force of each locomotive being about one-third of its weight, and the total efficiency of the system 68 per cent.

(*c*) The power station of the Mont Salève line (summit level, 3,700ft. above the sea) is situated about a mile from the line, and comprises two low-pressure turbines and two separately-excited Thury multipolar dynamos mounted on the vertical turbine shafts, and giving, at the low turbine speed, 500 h.p., or only a quarter of their combined normal output of 2,000 h.p. The 12 motor cars are each fitted with two 30-h.p. four-pole Thury motors, with double spur gear reduction, and current is taken from the outside conductor rails by metallic slide contact shoes. Owing chiefly to the unnecessarily heavy gearing, the total efficiency is only about 52 per cent.

(*d*) At Genoa the power station is about 1·3 mile distant from the line, and contains at present two boilers, two compound condensing Tosi 160-h.p. engines, and two belt-driven 110-kilowatt Siemens inner-pole dynamos. The present line, which is the nucleus of a projected suburban system, is worked by six cars, each fitted with two 16-h.p. Siemens motors, the reduction being 10 to 1 by chain and toothed wheel. Current is taken from the overhead wire by two Siemens and Halske's rectangular metallic contact frames.

(*e*) The Zurich power station is placed at the upper end of the line, and comprises two boilers, two 100-h.p. Oerlikon vertical engines and dynamos, together with an accumulator battery of 300 Tudor cells for compensating the variations of load of the steam-engine. The 12 motor cars are each fitted with two 12-h.p. Oerlikon motors. The total efficiency of the line is 65 per cent.

(*f*) At Barmen, the power station is situated at the foot of the incline, and contains two 225-h.p. compound condensing engines driving direct two Siemens inner-pole ring dynamos, whose output is 155 kilowatts each. The line is worked by 10 motor cars, each provided with two 36-h.p. Siemens motors, which by single spur gearing actuate the rack pinions mounted direct on the car axles. The total efficiency is like that of the other lines, from 60 to 65 per cent.

(*g*) *Conclusions.*—It is seen that the primary generating power is steam on the Florence, Genoa, Zurich, and Barmen, and hydraulic on the Murren and Mont Salève lines, the dynamos being direct-driven in four, and indirect in the other two cases. Notwithstanding the high cost of fuel in Italy and Switzerland (as much as 30s. per ton), and the steep grades on the Florence, Genoa, and Zurich lines, the running expenses do not exceed 4·5d. per car mile, while the total working expenses, including administration and renewals, are within 7·5d. per car mile, or about 50 per cent. of the receipts. On the Murren and Salève lines the cost of hydraulic power per annum is of course restricted only to wages and repairs. In the former case the working expenses do not exceed 40 per cent. of the receipts, while in the latter they are as much as 80 per cent., this high rate being due chiefly to inadequate fares. A specially noteworthy feature is the steady speed of eight to ten miles per hour with which motor cars run up the steep adhesion inclines of 6, 7, and 8 per cent. at Zurich, Genoa, and Florence; while on the descent a speed of even 15 miles per hour has proved perfectly safe, in conjunction with the powerful and instantaneous action of the electric safety brake constituted by the motors acting as dynamos on the descent, although for all ordinary purposes even the mechanical brake alone suffices to stop the car within its own length. As regards the comparative working cost of steep-grade adhesion or rack railways by steam and by electricity, I can affirm from my own experience, as well as from every other case which I have had occasion to investigate, that irrespective of the immensely greater elasticity of the service, and consequently the far more rapid development of the traffic, electrical working ensures an economy of at least 50 per cent. as compared with steam.

General Conclusions.

With regard to electrical traction on flat as well as steep-grade lines generally, I am led to the following conclusions:

Direct and Indirect Driving of Generators.—Although direct driving, whether by steam-engines or by turbines, is the ideal standard, and therefore always preferable, it cannot, for tractive purposes, be laid down as a dictum *à priori*. On lines having steep, and more especially alternately rising and falling grades coinciding with sharp curves, an intermittent traffic, and frequent stoppages, the variations of load are so great and so rapid—often from zero to maximum in the space of one minute—that vertical high-speed engines suitable for direct driving generally work very unecomically. This is, *e.g.*, the case at Florence, and in an even greater degree at Marseilles, where the high-speed direct-driving engines have actually to be replaced by horizontal low-speed Corliss engines, with belt driving. In the case of hydraulic power, high-pressure turbines always admit of economical direct driving, whereas low-pressure turbines involve for direct driving proportionately larger dynamos, giving only part of their normal output, so that here, too, indirect driving by gearing or belt is generally more economical. The same applies where gas-engines are used.

Steam, Hydraulic, and Gas Generating Power.—The first cost of an hydro-electric installation often exceeds that of steam plant, more especially in the case of a variable volume and small head of water, involving the use of low-pressure turbines. High-pressure turbine installations are always preferable and more economical. Where cheap hydraulic power is not available within a distance of about four miles from the line and fuel is dear, gas manufactured on the spot is much more economical than steam power.

Conductivity of Rails.—Where the rails serve as return circuit, the ordinary fishplates should have the same sectional area as the rails, so that, together with stout fastenings, they make a joint as stiff as the rail itself. In this way, and especially when laid on metallic sleepers, the permanent way gives 80 per cent. of the required conductivity at the joints; so that only 20 per cent. has to be made up by copper bonding, plus an adequate margin of, say, 10 per cent. Solidity, compactness, and careful maintenance of permanent way, as is usually found on electrical lines, as well as on railways generally in Europe, go far to make up for the elaborate copper bonding which the often defective condition of permanent way necessitates on American lines. It is for the same reason that electrolytic action on gas and water pipes, which is so common a phenomenon in the States, is practically unknown in Europe.

Conductor Rail.—Where a conductor rail is used, it should preferably be placed outside, instead of inside, the ordinary rail, because the outside conductor obviates all complications, and the contingency of short-circuit at points and crossings. On specially steep grades, involving the use of a central rack, the rack rail or bar itself, having continuous contact with the pinion wheels, constitutes an excellent conductor, provided it be effectually insulated from the sleepers by porcelain bells serving as supports.

Overhead Trolley Wheel and Slide Contact.—Contact by a trolley wheel whose spindle is rigidly held by the trolley pole is suitable for lines on which straight sections and flat curves predominate; but for lines with numerous and sharp curves, the rectangular single or double slide contact frame, as used by Messrs. Siemens and Halske on their overhead lines, is far preferable. It is lighter and more pleasing in appearance than either the rigid trolley, the flexible South Staffordshire trolley, or the slide contact bars used on the Isle of Man line. It obviates, moreover, many of the objectionable cross and diagonal wires, and hence the infinite variety and complexity of fastenings which the use of the rigid trolley wheel involves, and many of which, however neat as mechanical contrivances *per se*, are not exactly ornamental objects when suspended at a height of only 20ft. above the roadway. The only defect to which the Siemens slide contact is subject consists in the upper, slightly arched, and, of course, renewable contact side of the frame being liable to become grooved, whereby the easy play to right and left of the contact wire is impaired; but this defect can be easily remedied by employing material of adequate resistance. Another and very simple form of slide contact is that used on an electric road railway from the Lake of Lucerne to the foot of Stanserhorn, and consisting in a crescent-shaped grooved contact-piece of bronze, which is loosely hinged to the trolley pole, and thus, in conjunction with the lateral play of the pole, adjusts itself to the sinuosities of the line.

Underground Contact and Accumulator Cars.—It is generally recognised that the overhead trolley system, which in reality is only a makeshift, is unsuited for the central parts of the large towns, and *a fortiori* of the metropolis of this country, and the same applies equally to the other largest capitals of Europe—to wit, Paris, Berlin, and Vienna. In these cases, the conduit system or accumulator cars are therefore at present the only practicable solution of the problem. In Europe, the conduit system, whether it be that of Budapest, or with a central slot, may be estimated to cost complete £10,000 per mile and upwards, according to local conditions, though this is not too costly having regard to the enormous traffic in large towns; but its efficient working presupposes, among other things, very perfect drainage of the trench. As regards accumulator cars, they would really constitute an ideal form of electrical tramway traction, if the present car weight of 12 to 15 tons and the power and traction expenses of 8d. to 10d. per car mile could be reduced to half. As a case in point may be quoted the unwieldy accumulator cars which run on the Madeleine and St.-Denis tramway in Paris, and give fairly satisfactory results, but which, owing to their heavy weight, are not infrequently deficient in torque on the long 1 in 20 grades, when the motors become saturated. The overhead system, on the other hand, is very well adapted for suburban tramways, and eminently so for light railways and road railways in the country. The cost of such road railways, if constructed on the metre or 3ft. 3in. guage, can well be kept within £6,000 per mile, including electrical equipment, and the already quoted road railway from the Lake of Lucerne to the foot of Stanserhorn, which only cost £4,500 per mile, as well as another similar line near Bâle, have demonstrated what a cheap and convenient motor-car service can do in essentially agricultural districts.

Digitized by Google

Gearless and Geared Motors.—Gearless motors are eminently suitable for high speeds, while for low speeds they require to be of inconveniently large size. For geared motors single reduction is of course always preferable, although on exceptionally steep grades, where the motors have to develop their maximum power at minimum car speed, double reduction may in some cases be unavoidable. In any case, spur gearing is always preferable to worm gearing or chain motion, both of which involve too much friction and consequent loss of power.

Parallell and Series Coupling of Motors.—This much-debated question cannot be decided *à priori*, but depends on individual cases. For level or easy-grade lines parallel coupling is more suitable; whereas on steep grades, where starting requires always the maximum torque, series coupling is generally called for.

Variations of Load.—On lines with steep or rising and falling grades, these variations cannot be mitigated, much less equalised, simply by increasing the number of cars or trains on the line, since the variations are caused not only by the varying traffic, but by the varying grades and curves, and by the varying degrees of adhesion, more especially in starting. Where separately-excited dynamos are used, a partial means of compensating the variations of load is, as well known, that of varying the excitation by the main current passing through the exciter. But the most effectual remedy is the addition of an accumulator battery, which absorbs an excess of supply from the generator over demand on the line, and, *vice versâ*, makes up for any deficiency of supply, so that the steam-engine and generator can always run at full and constant load. Accumulator batteries have fully vindicated their claim as an important auxiliary and as a means of economical working of traction installations at Zurich, and subsequently in the Isle of Man, and well repay the additional first cost of plant.

Continuous and Alternate Current.—Hitherto continuous current has been exclusively used for electrical traction. But, having regard to the high degree of efficiency and perfection and the ease of starting recently attained in alternate-current motors, thanks notably to the persevering efforts of such constructors as Messrs. Brown, Boveri, and Co., it may be confidently predicted that, as in lighting installations and in power transmissions for industrial purposes, so also in electrical traction alternate is destined to supplant continuous current. Alternate current, whether single or multiphase, will not only admit of electrical traction being applied over much longer distances than is economically possible with continuous current, but it will ensure a saving of something like 30 per cent. in the weight of dynamos and motors, irrespective of the saving in copper of feed and contact wires, and will thus considerably simplify and cheapen electrical installation and equipment for tractive purposes. But whether by alternate or by direct current, on flat as on steep-grade lines, on so-called light railways as on tramroads in town and country, we may be well assured that electrical traction in its various forms has, both in this United Kingdom and throughout Europe, a brilliant and triumphant future.

After Mr. Preller's paper had been read, **Mr. Siemens** voted thanks to him, but hoped when the paper was reproduced in the *Journal* he would leave out some of the interpolations which had been made.

A Member said that the Passadena line in California, was a pleasure railway, leading people from summer to winter, being a line to the top of Mount Wilson, which was 13 miles long, and which reached an elevation of 7,000ft., and which for a time had a gradient of 7½ per cent., and afterwards of 1,600ft. in 3,000ft. The work was done by means of a cable actuated by means of a 75-h.p. electric motor, the motor getting its current from dynamos driven by Pelton water-wheels. It was intended to derive water power 400ft. below the summit, pump it up by electric motors, and let it fall to a considerable depth, whereby it was anticipated that a considerable amount of spare power would be available.

Mr. Robinson only wanted to look at the commercial aspect of the question. His living was partly bound up with the development of electricity, and electric traction was going to be of great magnitude. By the development of electric traction electricians would benefit and so would the public. Not forgetting what had been done in this country, America showed us what could be done in that line. Mr. Robinson praised Mr. Preece for the information which he had given last session, stated that Mr. Wilkinson had assisted in giving valuable information, and Mr. Blackwell interesting details. As one of those who expected something to come of electric traction, he thought thanks were due to the various authors. He considered that Mr. Preller was not quite in touch with the general subject, for he had dealt with mountain railways, which were not well suited for this country. As regarded Mr. Preller's observations about high-speed engines, that point should have been raised some years ago.

Mr. Parshall said that the most important point which had been raised was that of earth return. The result of close study was that the difficulty could have been avoided if engineers had carried out what they knew. When they had an underground contact of copper with iron they could not expect 50 amperes per square inch when they did not expect as much under better circumstances. This was an evident source of trouble. The proportion of the contact between the rail and the bond should be according to the amount of current. The contact area should be 20 times the cross-section. The difficulty could be overcome by the adoption of electric welding, and he recommended the use of an electrically-welded underground system everywhere. The power required on electric lines was, with an average number of stops, one Board of Trade unit per car mile, the deviation in Europe not being more than 15 per cent. The watts per car mile remained constant for various rates of speeds. With a series parallel controller and frequent stoppages two motors were preferable. The speaker advised working cars at the highest rate of speed. In the United States the rate of speed in the crowded streets was three or four miles an hour, and in outlying districts 20 miles an hour. The number of persons killed was in inverse ratio to the speed of the cars. English engineers might demonstrate to the Board of Trade that a higher rate of speed than was now allowed was allowable. As regarded alternators, he did not expect that polyphase motors would be used, the only approach to that being triphase motors. After describing the intramural Chicago Exhibition electric railway, with which he had been connected, he stated that great fluctuations in power should be avoided, and it would result in economy if smaller engines could be used.

Captain H. Sankey started off with the subject of stresses in flywheels, stating that there was no risk with small disc flywheels in a direct-driven set. If a short circuit took place, the engine might suffer, but he thought that the armature would instead. He had worked out the problem, and he showed a diagram indicating the torsional stresses in the crank-shaft due to stoppage by circuit. There was no stoppage possible within one-three-hundredth of a second, and that was the first which would break an ordinary steel crankshaft. In a direct-driven set the only difficuty would be in the armature. All that had to be taken into account was the construction of the armature and of the crank.

Mr. Holroyd Smith, in regard to Mr. Wilkinson's statement that in conduit systems it is better to have them placed in the centre of the track, said that he would not like to be as definite as the author of the paper. The conduit system illustrated on the wall as in operation in the United States was interesting from the fact that it was constantly recurring under different names. He complimented Messrs. Blackwell and Dawson on their paper, because they had not contented themselves with abstract figures, but had shown them how the things were done. After criticising the sliding arrangement of trolley collector, the speaker observed that the fishing rod or trolley pole had originated with Mr. Sprague, and the thanks of the electrical world were due to him for it. In fact, he took that opportunity of expressing his obligation to him. There was, he thought, plenty of scope for a paper dealing with trolley rods and their wires. The methods described in the papers were, however, inapplicable to double deck cars, such as used in this country. In this connection he referred to a trolley arrangement for tramcars having imperials, and which had been tested by him at Bradford. This method, which he sketched on the blackboard, allowed of a uniformity of pressure being obtained. The arrangement consisted in the use at rear of the car of a vertical swivelling rod, having projecting at an angle from it the trolley pole supported by levers and a spring, the spring being put into greater tension when the rod is brought down. Comparing the American form of trolley pulley with that devised by himself, the speaker showed how the latter easily allowed of sharp curves being taken without the trolley pulley coming off. One of the rail bonds described in the papers was very similar to that introduced by him ten years ago in the case of the Blackpool tramway. In this connection it was interesting to note that during the repairs of that line early this year, some of those bonds had been brought to light, and had been found to be in an excellent condition. He had long advocated double-tread rails as being better than those ordinarily used, and he exhibited a type of rail which he stated afforded an effectual means of contact and exceptional facilities for bonding.

The **President**, in adjourning the discussion, said that the next meeting, which would be the annual general assembly, would take place on December 13, and that the next students' assembly would be held on Friday, November 30, when a paper by Mr. G. Wright on "Central Station Working" would be read. At the conclusion of the business of the annual meeting the discussion on the traction papers would be resumed.

Before the regular proceedings of the evening began, **Mr. Siemens** spoke in terms of regret of the death which had occurred of Colonel Armstrong, who, he said, had assisted greatly in the development of submarine telegraphy, and who was the first electrical adviser to the Board of Trade.

Electric Lift for Goods.—An electric lift designed for a load of 10cwt., and having a speed of 1ft. 8in. per second, has been arranged in the works of Messrs. Naglo Bros. in Berlin. The motor, which is of 5 h.p., and runs at 800 revolutions a minute, is coupled to the winding drum by means of gear, and the lift is used for the raising and lowering of goods.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

AN EPIDEMIC OF SHOCKS.

Every now and again there occurs a series of accidents, more or less serious (though usually it is to be feared of the former character), due to the usual foolishness of persons who insist upon looking for a leak of gas with a lighted candle—and find it, when the windows and doors are blown out. Slight misadventures of this kind do not, of course, entirely put an end to the use of gas—it would be absurd if they did; we merely mention them to recall the curious frequency with which there seems to occur a series of such accidents, followed by a short interval of comparative freedom from them, due possibly to the exercise of greater care and common-sense for the time being whilst the moral effect of these explosions yet endures.

It is not in any way remarkable that they should occur: the philosopher will regard them as inevitable accompaniments of any illuminating system where gas is employed, just as slight accidents are certain to happen in electric lighting circuits distributed in similar fashion over an entire town or city for general service. There is, however, at least one very striking point of difference: the ordinary individual or atom of the public mass can in practice never act so foolishly with an electric circuit as to do serious harm either to himself or others.

It has been affirmed that there is more danger to the workmen and others engaged in electric lighting than to the workers employed on a gas-lighting system: we doubt this, in the first place; and, secondly, even if it be true, the men are fully aware of what danger there may be. Still more is this realised by the engineers who have charge of the system: and their efforts are constantly directed to safeguarding the employés as well as the public. One proof of the care with which the latter object at least is effected lies in the fact that Mr. Cook, the engineer of the City of London Electric Lighting Company, stated that a far greater number of people would be maimed and killed by slipping on orange-peel in the streets of London than were ever likely to be injured or killed by electricity. He had not heard of any consumer or other person not connected with the works being killed since the inauguration of the City lighting. Accidents to workmen and employés, moreover, are not and have not been in any way so numerous as those to the general public from leaks of gas, and a proof of this lies in the title we have given to these remarks. To have three or four accidents (of which one has, unfortunately, proved serious) within the past fortnight, prompts us to speak of them as forming an "epidemic."

With regard to the occurrence in the City—particulars of which appear elsewhere in a report of the Board of Trade enquiry—we are, of course, not yet in a position to comment fully upon the facts or the bearing which they may have upon present methods: not only is the enquiry adjourned, but even if it had been concluded we should require to await the publication of Major Cardew's report before venturing any criticism or expression of opinion. Speaking from a general standpoint, we note with pleasure that the electric lighting com-

Digitized by Google

pany freely admit the mistake made at their works which caused the short-circuit and subsequent charge of a street and pavement area, leading to the death of a horse and injury to passers-by from shock and contusions due to the broken junction-box lids, etc., and trust sincerely that in this case the well-known adage applies: "a fault confessed is half redressed," so far as concerns the possibility of any future incidents of the same kind.

More serious and regrettable is the fatality referred to in our correspondence columns occurring to an employé of the Taunton electrical works. Even in this case, however, there seems no absolute proof that death was due to shock; it is to our mind essential that the medical evidence should be absolutely conclusive, and a mere opinion is not sufficient to place this lamentable affair in the category of electric accidents. Moreover, as with the case at Blackpool, instanced in our "Notes" column, the fault or responsibility rests clearly upon the employé himself, for all possible precautions appear to have been taken at the Taunton works to prevent the occurrence of any accident whatever; and if the unfortunate man suffered fatal injury from shock, it seems hard to see how this was possible otherwise than through absolute carelessness. The same criticism must be made with regard to the foolhardy lamp-trimmer at Blackpool. Anyone who attempts to wipe out a loaded gun at full cock would be considered, to put it euphemistically, somewhat less wise than Nature intended him to be. Workmen who will not avail themselves—through carelessness, or worse—of the means provided to give them adequate protection, must bear the consequences of their own folly.

At Keswick, the breakage of an overhead line seems to have caused it to be grounded through an iron spout and pathway gutter, but the hardy Northmen rather enjoyed the sensation of shock; and whilst the current was thus more or less short-circuited, the harmless antics of involuntary victims appear to have amused a number of those who had previously suffered. This is a typical instance of the fact, which should be laid well to heart, that the general public run practically no serious risk whatever from any well-conducted electric lighting system: and epidemics of shocks will in all likelihood recur not only very seldom, but after intervals increasing in length of time.

REVIEWS.

Electric Transmission of Energy and its Transformation, Sub-Division, and Distribution. By GISBERT KAPP, M.I.C.E., etc. Fourth edition. Thoroughly revised. Whittaker and Co.

When public appreciation of a book has been so practically demonstrated as to demand a fourth edition, any words of commendation must necessarily appear feeble. The fiat of success has gone forth, and all the critic can say will hardly add or detract from the verdict such a demand shows. In this case, however, the honest critic is perforced to agree with the public verdict, and, if he says anything, to admit that the success is well merited, and, indeed, if anything, is insufficient. Mr. Kapp, if we mistake not, was the first author to attack this problem of transmission, and from his first edition to the present he has kept himself and his readers well abreast of all that has been done in this direction. Mr. Kapp starts with an immense advantage. It is nothing to say he is a painstaking student. He is that and far more. Authors, as a rule, are followers, and not pioneers. Mr. Kapp is not a follower; he is also more than a pioneer—he is an original thinker and a practical man. The ordinary author has usually in mind the requirements of a mere student; this author has another goal, the requirements of the practical constructor and designer. We may admire the late Dr. Todhunter's book on mechanics, but a study of that book never assisted any man to build a steam-engine. Mr. Kapp gives us not the scholastic problem to solve, but the workshop problem, and places in our hands the necessary information to solve such problems. Theory is made a tool, and the way to apply the tool is clearly indicated. In fact, we know of no other author that in this particular subject comes anywhere near Mr. Kapp for practical insight, for terse and clear explanation of all that concerns electrical transmission of energy. This edition has been largely revised. It is almost a new book, and will bear the closest study. Of course, it would not be English-like if we did not introduce at least one grumble, and let us say at once we detest the new symbol for revolutions per second. Bother so much symbolism, and especially such a symbol! Have some consideration for printers and typefounders, whose charges for mathematical work are large enough now without introducing much that is strange. But to return to the book. The first six chapters are somewhat on the same lines as the corresponding chapters in the previous edition, and these constitute the first half of the book, which now, instead of nine chapters, is extended to twelve, the last six being almost all new matter. It is needless to say that this new treatment of alternating current, self-induction, armature reactions, frequency, single and polyphase motors, and similar questions of late becoming prominent, is as able as anything the author has ever written. As we have said, the treatment throughout is with a view to direct practical application, and the needs of the worker are never forgotten; hence this book is one which must of necessity be found in the hands of everyone who desires to become acquainted with the best and latest information on the subject.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

USE OF MICANITE.

SIR,—We notice in your issue of the 2nd inst. a reprint of a circular concerning the manner in which "micanite" should be used. As you therein merely mention the name of our American friends, without giving any address, this might prove misleading to many of our customers or "would-be clients." As you are aware, it was we, as sole European agents for the Mica Insulator Company, who introduced this form of insulation into the European markets, and we are glad to say that our efforts have been very amply rewarded.—Yours, etc.,

13, Walbrook, E.C. BERGTHEIL AND YOUNG.

ELECTRICITY FROM GAS.

SIR,—I have read with interest your article entitled "Electricity from Gas" published in your issue of last week, and referring to the elaborate demonstration station recently erected at Stoke Newington for the Motor Gas Syndicate from designs supplied by Mr. B. H. Thwaite.

With reference to this plant, I may state that having been instructed by the owners to make a lengthy test and report on the general efficiency of the plant under different conditions of working, I devised one of the "ingenious improvements" noticed by your representative in the shape of "a little arrangement attached to the gas-engine, by means of which a tiny piston, acting in a small cylinder connected with the main engine cylinder, actuates a needle so as to punctuate a paper strip at every cylinder explosion." This arrangement was fitted to the gas-engine erected at this station, at my suggestion, with the view of

Digitized by Google

determining the horse-power with greater accuracy than is usually done in the case of gas-engines, and it answers its purpose admirably. It could easily be made to form an integral part of indicators intended for gas-engines.—Yours, etc.,

GEO. CAWLEY.

29, Great George-street, S.W., November 19, 1894.

ACCIDENT AT TAUNTON.

SIR,—As there appear to be all sorts of rumours afloat as to the unfortunate fatality at these works, I am sending you the enclosed facts concerning the case for use at your discretion amongst your columns. I am sure you will agree with me that in the interests of the electrical industry it is highly desirable that one avoids any appearance of sensationalism, and therefore I send you the facts.—Yours, etc.,

HAROLD W. COUSENS,
Borough Electrical Engineer.

St. James's-street, Taunton, November 19, 1894.

[ENCLOSURE.]

About 6.45 p.m. on Tuesday, November 6, Warren Upham, a pupil of the Corporation, was seen by a labourer (who was washing a portion of the floor) going towards No. 1 alternator (70-unit Thomson-Houston) with an oil-can to replenish the bearings. A minute later he was found leaning against the bed of the exciter and belt-guard behind, apparently dead. Medical aid was at once summoned, but of no avail. There were no marks on the body, save an abrasion on the left arm caused by the belt of the exciter as the body lay. The doctor made a *post mortem* examination of the body and found the organs healthy. He was of opinion that death was due to an electric shock. There was no evidence to show how the shock was received, as no one witnessed the occurrence. The inspector of factories attended the adjourned inquest on the 15th inst., and expressed himself perfectly satisfied with the precautions that had been taken to guard against accidents. To quote a local paper anent the occurrence: "At the Taunton electrical depôt it would be difficult to provide more precautions than at present exist. It is for the assistants to make use of the precautions offered them and there will be no danger." The jury brought in a verdict of accidental death caused by an electric shock, and wished to add that, if possible, greater care should be taken to insulate the dangerous parts of the machine, and a safer system of oiling should be adopted.

ALTERNATING CURRENTS AND FUSES.

In a recent issue of the *Transactions* of the American Institute of Electrical Engineers is published a paper on this subject by Prof. Dugald C. Jackson and Mr. R. J. Ochsner. The paper, which is illustrated by diagrams, forms a report of an investigation made by Mr. Ochsner in the electrical engineering laboratory of the University of Wisconsin. The work was undertaken with a view to studying the disintegrating effect of alternating currents on fuse metals, and, if possible, to ascertain the cause. As the work done at Cornell University last year showed such a remarkable rise of resistance and a lowering of the fusing points of the fuses placed on the alternating circuits, Mr. Ochsner decided to repeat the experiments, and if any change in the resistances should take place to prolong them.

As a result of his tests on the effect of alternating currents on the resistance of fuses, Mr. Ochsner states that these experiments prove that there is no appreciable rise of resistance in fuses subjected to alternating currents, at least not within a period of 550 hours. More accurate results might undoubtedly have been obtained had the fuses been mounted in such a manner as to avoid contact with any large masses of solid material, but the accuracy is amply sufficient to prove the case. These results are diametrically opposed to those given in the report of similar work, published in the *Transactions*, vol. x., p. 262. While in the latter investigations corrections were made for the standard resistance with which the fuses were compared, no such corrections were made for the fuse wires. The fuses were subjected to larger currents than in his tests, with consequent greater heating. The resistances were apparently measured without allowing sufficient time for the fuses to acquire the temperature of the room, and even if this was done the variation in temperature of the room, as given in the original report of the investigation (which Mr. C. P. Matthews, instructor at Cornell University, kindly sent him), was sufficient to introduce serious errors. The resistances were measured by the fall of potential method. According to the drawing, showing the arrangement of the apparatus, no extra resistance is put in series with the battery to reduce the current strength. This current may have been sufficiently great, in the smaller-sized fuses at least, to cause considersiderable heating. For these and other reasons relating to the accuracy of the tables, he thought that this part of the work reported by Mr. Matthews was not to be relied upon, and, therefore, the conclusions based upon it are of no value.

In regard to the effect of alternating currents on the fusing points, four of the samples exhibited showed a slight lowering, while two show a slight rise in the fusing point, but the differences are of the same order as the differences between individual test pieces. While a test of only a comparatively small number of fuses in this way hardly establishes the correctness of the results, a slight change in the fusing points probably did take place, as is shown by the fair uniformity of the figures in each sample. That such slight change as did occur was due to oxidation there is also little doubt, for all of the old fuses showed slight oxidation, and the effect is too small to be of practical moment. As to the results in the earlier investigation already referred to on the fusing points, only the averages are given, and no mention is made of temperature; therefore it is impossible to properly judge of their accuracy. As far as can be determined from the original report, however, the tests do not seem to be any more reliable than the resistance tests.

In the light of the experiments herein described, and the statements made by Cockburn, Salomons, and Matthews, is it necessary to ascribe a slight change in the properties of the fuse to the disintegrating effect of the alternating current? The author thinks not. In practice, a fuse is seldom obliged to carry a current equal to its full rated capacity. In electric lighting, for instance, the lamps protected by a fuse are not likely to be all turned on at once, and therefore the fuse is seldom carrying more than a small part of its rated capacity. The experiments that he has made, therefore, represent the conditions of ordinary practice, and prove that a fuse as used in practice is not directly affected by the alternating currents. Fuses on alternating-current circuits are sometimes found to blow without apparent reason, but something outside of the disintegrating effect of the current is the cause. Under some conditions the result has come about through the mechanical shaking to which an alternating-current fuse is sometimes subjected when not tightly clamped by the terminal screws.

CITY AND GUILDS OF LONDON INSTITUTE.

LECTURE XI.—GENERAL DESCRIPTIVE KNOWLEDGE OF MAGNETS AND ELECTROMAGNETS.—BEST METHOD OF WINDING ELECTROMAGNET COILS FOR VARIOUS SERVICES.

(Specially contributed.)

Magnets.—I may perhaps be allowed to put the cart before the horse, and begin this portion of my subject with the consideration of the artificial rather than of the natural magnet. My reason for this transposition is that the artificially-made electromagnet is vastly more important in industrial work than is the natural magnet or lodestone, or the artificially-made permanent magnet. I have used the word permanent just now, from which you will—and justly so—infer that the electromagnet is not permanent.

Digitized by Google

Field.—When speaking of the voltaic cell, I told you that effects are produced in the space around the external conductor. I have here a very simple circuit, Fig. 1, through which a current is flowing, and I have also a kind of pepper-box, which, instead of pepper, is full of iron filings. I sift these iron filings over the circuit and you see that

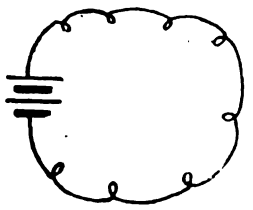

FIG. 1.

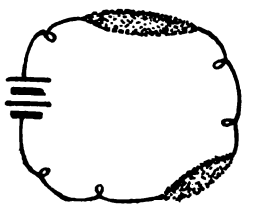

FIG. 2.

some of the filings cling to the wire, Fig. 2. No matter what part of the wire I shake the filings above, you see some of them cling. If I break the circuit, the filings fall off the wire.

I have here a plate of glass, through the centre of which I can pass a conducting wire, Fig. 3. I send a current through

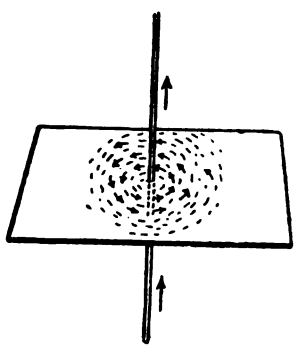

FIG. 3.

this wire, and shake some of the iron filings on to the glass. See, they do not tumble anyhow, but arrange themselves somewhat symmetrically around the wire. They look as if they arrange themselves in concentric circles. I try shaking the filings on a similar piece of glass without the conductor, and, see, they fall anyhow. There is now no arrangement. Now, what caused the filings to arrange themselves symmetrically around the conductor? I do not know. The action, however, is due somehow to the current going through the wire; for if I try with the wire through the glass, but no current in the wire, you see the filings fall unsymmetrically, just as they did upon the glass plate without the wire.

Hence we must suppose that the current has some influence in the air space immediately around the wire. This influence we term *magnetic influence*, and the space around the wire in which this influence is exerted we call the *magnetic field of the conductor*. It is very usual to call this magnetic influence *induction*, and to say the filings are acted upon by induction or inductively. But these filings we shall find not only are influenced themselves, but in their turn, so to speak, become centres of influence, and will act upon other filings.

I have here a small permanent magnet which I will suspend by this silk thread a little above the glass plate while there is no current in the wire. You can see its shadow on the screen. Now, watch while I make contact and send a current through the wire. You see the magnet and shadow move, coming to rest in a certain position. I pin a strip of paper along the centre of the shadow pointing to the ends—that is, pointing in the same direction as the long axis of the magnet. I now reverse the direction of the current as quickly as I can. You see the magnet and shadow turn right round and the magnet comes to rest. The long axis of the shadow is again exactly along the strip of paper. The two ends of the magnet are now just in the opposite direction to their original position, but the line drawn through the ends has not changed. A careful examination of the lines of filings and the position of the magnet will show that the line drawn through the ends of the magnet is tangential to the lines of the filings. These later are circular in form with the wire at the centre, and the filings form a series of concentric rings around the wire. If we had thin plates of glass all along the wire, we should be able to obtain similar phenomena so long as there was a current. The conductor would then be surrounded by circular rings of filings forming a kind of whirl around the wire, Fig. 4. The single whirl with the concentric circles may be shown more clearly by Fig. 5. We

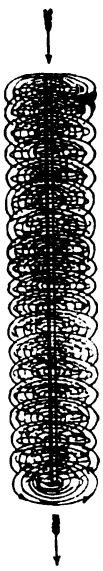

FIG. 4.

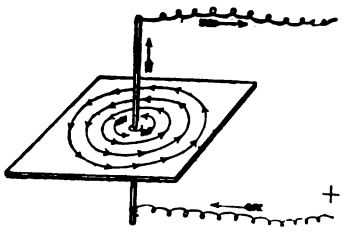

FIG. 5.

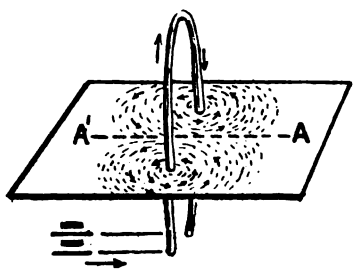

FIG. 6.

may learn something more by bending the wire back on itself, as in Fig. 6. The circles of filings, instead of being concentric around each wire, are now in the space between the wires pushed closer together, and the direction of the filings along the central line between the wires becomes for a short distance almost, or quite, a straight line.

Lines of Force.—As I have said, we do not know the actual cause of these phenomena, but Faraday suggested an excellent working hypothesis, and using this suggestion assists us greatly in understanding the various phenomena of magnetism. He said we might suppose forces radiating from the conductor or from the magnet, each individual force being termed a "line of force." Hence we may suppose the magnetic field to be made up of "lines of force." The greater the number of these lines of force in a given space, or the greater their density, the greater is the strength of the field.

The circular lines of force found along the whole length of conductor are not lost if the conductor be bent completely round upon itself. If Fig. 7 represents the lines

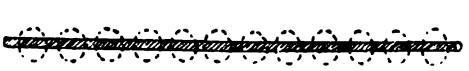

FIG. 7.

of force in the straight conductor, Fig. 8 may be taken to represent a single coil of conductor in which the lines of force will be seen to thread the coil.

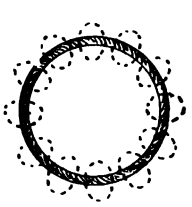

FIG. 8.

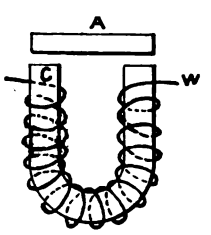

FIG. 9.

All our experiments hitherto have been with air as the material in which the magnetic field is formed, but we may use instead of air something which offers a less resistance to these lines of force, such as soft iron, and then we might expect the current which forced a given number of lines of force through air to force a greater number of "lines

Digitized by Google

of force" through the material which has less magnetic resistance. And this is so. Thus in magnetism, as in voltaic electricity, we have three principal phenomena to investigate.

In voltaic electricity we had to consider a *pressure* to force a *current* through a *resistance*.

In magnetism, also, we have to consider a *pressure* to create or push "lines of force" in or through a given *resistance*.

The magnetic pressure in the electromagnet is due to the current in the coils surrounding the core.

The lines of force created answer to the current in the voltaic circuit; and

The magnetic resistance of the iron core of the air space between the armature, Fig. 9, and the core and of the armature combine to make up the total magnetic resistance of the magnetic circuit.

Thus we get in magnetism a law similar to Ohm's law in voltaic electricity. It may be written:

$$\text{Number of lines of force} = \frac{\text{Pressure due to current in magnet coils}}{\text{magnetic resistance}}$$

I have shown you that a single loop of conductor has a circular field around it. If a second loop be added to the first, and another to that, and so on, the magnetic field, Fig. 10, if found to exist all round the loops. A careful

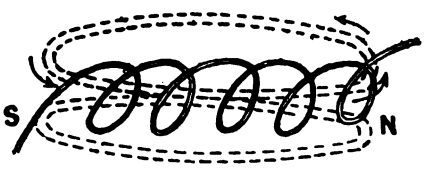

FIG. 10.

examination of the iron filings shows that they form closed curves of filings, and we therefore assume that all lines of force formed closed curves of force. Each of these curves threads the loops. If I arrange the loops, Fig. 11, so as to form

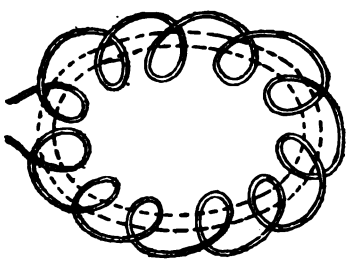

FIG. 11.

a ring of loops, the whole of the lines of force are found in the interior of the loops, as that circuit forms a complete circuit, and is the shortest, hence offers the least resistance.

With the conductor loops as I have shown them the lines of force have to traverse the air, and air offers a great resistance to them. If, then, a series of loops carrying a current, as in Fig. 10, act as a magnet, we must come to the conclusion that the magnetic action is due to the lines of force.

Now a magnet has certain characteristics:

1. If freely suspended it will take up a position so that its ends point towards the magnetic poles of the earth. This is a direction not quite the same, but nearly so, as the geographical poles.

α. If an apparatus consisting of a series of coils, as shown in Fig. 12, be freely suspended by immersing the terminals of the wire in mercury-cups, as in the diagram, and a current is sent through the coils, the conductor does take up a position pointing north and south, as indicated. A series of coils of this kind is termed a *solenoid*.

2. A magnet pulls small pieces of iron towards itself when the small pieces of iron are placed within the influence of its field. I say small pieces of iron advisedly, because if the pieces of iron be very much larger than the magnet, the magnet will go to the iron instead of the iron going to the magnet. From this it will be assumed that the pull—if pull it is—is mutual. The action really arises from the property existing to shorten the magnetic circuit, or to lessen its resistance when the conditions are favourable. The pull of the magnet upon the iron is due to an effort to bring the iron into the circuit, and so lessen its resistance.

β. If small pieces of iron be brought within the influence of the field of the solenoid, there is an effort to pull the iron towards the centre of the coils.

The solenoid then acts as a magnet, and is a magnet. It is possible for us, roughly, to show the effect of placing a piece of iron in the circuit, and so decreasing the resistance of the magnetic circuit.

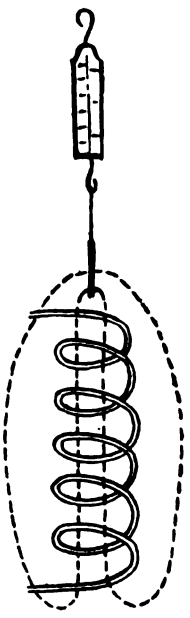

FIG. 13.

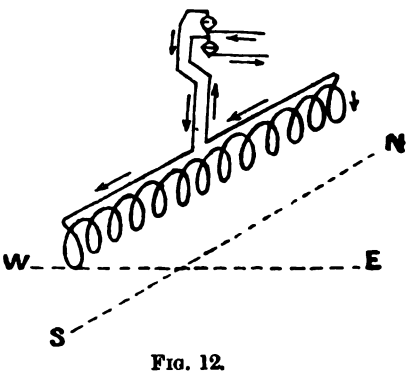

FIG. 12.

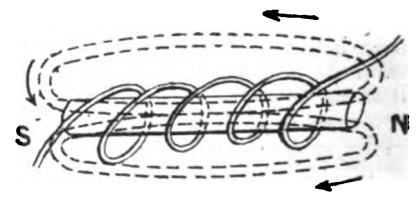

FIG 14.

Take the solenoid, Fig. 13; we place this small piece of iron at a certain point near the end of the solenoid. The iron is fixed to a delicate spring balance. Sending the current through the solenoid we see there is a pull upon the balance. Note what it is. The current sent through the coils is measured by this instrument. You see the indication upon its dial. I now break the circuit, and place this soft iron core in the solenoid. The piece of iron to be acted upon is exactly on the same spot, and we now send an exactly similar current through the coils. You see the pull on the balance is greater. The resistance of the magnetic circuit is lessened. The number of lines of force around the coils is increased; hence the number acting or pulling on the piece of iron are increased, and this increased number causes an increased pull.

It being found that air has a much greater magnetic resistance than iron, we usually fill up the core of the coils with soft iron, Fig. 14, curving the coils, or otherwise arranging them, so that the air space between the ends, or, as they called, the *poles*, is as small as possible, Fig. 15.

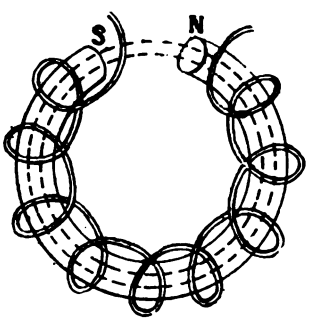

FIG. 15.

Later on we shall see it is impossible to do away with this air space in most instances if we want to utilise the "lines of force," otherwise the greatest number could be had, or the least resistance of the magnetic circuit would be obtained by making the core and coil circular.

INSTITUTION OF JUNIOR ENGINEERS.

ABSTRACT OF PRESIDENTIAL ADDRESS, BY ALEXANDER SIEMENS, M.I.C.E., PRESIDENT OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

It is not my intention to say anything to-night about the education of civil engineers, as this topic has been deal with by two of my predecessors not very many years ago, but I wish to draw your attention to a particular class of problems which from their very nature cannot be easily dealt with at a college. These problems are not confined to any branch of engineering, but are common to all of them, and have to do with the advancement of our knowledge and of our ability to utilise the forces of nature. When we look round and see how the civil engineer has transformed the conditions of living during the last hundred years, we cannot help being impressed with the change that has been brought about, and nothing is more natural than the thought that a further development of our resources and an increased command over natural forces are in store for us, and only wait for the right man to reveal them to mankind. That such men deserve special recognition has long since been admitted, and when, in the reign of James I., all monopolies were abolished, an exception was made by granting the privilege of the "sole working or making of any manner of new manufacture within the realm to the true and first inventor of such manufacture, which others, at the time of making such letters patent and grants, should not use, so they be not contrary to law, nor mischievous to the State by raising of the prices of commodities at home, or hurt of trade, or generally inconvenient." On this statute all the patent legislation of this country is based, and the effect of the law is that inventors are granted a monopoly for a limited number of years, on condition that they fully describe and make patent to everybody the particular nature of the useful novelty which they claim to have discovered or invented.

It is rightly assumed that, on the one hand, the time and money expended during the development of the novelty give the inventor a claim for compensation, and that, on the other hand, the usefulness of the invention is greatly enhanced if an opportunity is provided for everybody to obtain the description and full explanation of the latest developments in manufacture. A proof of the correctness of these principles is the unanimity with which all civilised nations have adopted them, although the methods of applying them vary a good deal. The success which has attended the efforts of many inventors and the constantly widening field for the utilisation of natural forces exert an ever-increasing fascination over our imagination, and when a young engineer enters practical life it is not to be wondered at if he dreams of the improvements he may introduce, and of the reward he will earn for his ingenuity. This is the right spirit with which to enter on life's work, for all true progress is based on genuine enthusiasm and proper self-confidence, which enable us to devote to our studies that earnestness and thoroughness without which no real advancement is possible. It is a popular superstition that inventors are heaven-made, and that they can produce useful novelties to order in any branch of manufacture, where a want exists, if only their attention be drawn to it.

The history of the invention of the steam-engine is a well-known illustration of the point I wish to emphasise. According to the popular version, Watt, as a small boy, saw the lid of the tea-kettle move up and down when the water was boiling, and this suggested to him the construction of the steam-engine. As a matter of fact, Watt made himself acquainted with what had been done before (a point altogether ignored in the popular version), and had to work very hard before he brought his invention to a successful issue. His example is typical of the true method of progress, and we may say generally, that in order to approach a problem with the best prospect of success it is necessary (1) to define as accurately as possible the want that exists, or the particular object that is to be attained; (2) to be well acquainted with the scientific principles which come into play; (3) to know how the want is met, or the object attained in practical life; (4) to find out what proposals have been made by others in the same or in a similar case. A careful attention to these requirements will prevent much disappointment and waste of energy, as will be obvious to all of you without further explanation.

It may, indeed, seem curious to you that I should dwell on such palpable truths, which must be patent to everybody who gives his attention to the subject, but you will very soon find out that inventions are brought forward every day by zealous people who have neglected to make themselves masters of one or more of these necessary preliminaries to bringing out a successful invention. In some systems of patent legislation, endeavours have been made to aid the struggling inventor by a preliminary examination into the novelty of the invention, but this is avowedly nôt conclusive, and does not protect the patent against attacks for want of novelty or lack of utility. It is, therefore, difficult to comprehend what object is served by this preliminary examination, and it is easily seen that this benevolent intention of assisting the inventor becomes really nothing more than an additional obstacle in his path. As a result of this we see that lawsuits about patents are quite as frequent in countries which have instituted a preliminary examination, as in those where patents are granted without it. In fact, a new type of patent suits is created by inviting opposing parties to lay their arguments before the examiner, and by requiring the inventor to refute them. Between such a suit and a suit for infringement before a law court there is little difference as far as time and money are concerned, but a gained lawsuit establishes your claim to an invention, while the favourable decision of a patent examiner carries practically no weight at all. There is the initial difficulty of determining whether a modification that somebody suggests in a manufacturing process is a patentable invention or not. Such a question was raised in connection with the famous Bessemer process of making steel.

In other countries, this question is treated differently. For instance, in France, an inventor can prevent other people using well-known devices if he is the first to apply them in a novel way or to a novel machine. By such an interpretation of his patent, Mr. Gramme succeeded in securing for himself the monopoly of using copper-wire brushes to take the current off at the commutator of dynamo-electric machines. It was of no avail to prove the use of such brushes in telegraph instruments or in magneto-electric machines; the French law recognised that Gramme was the first to utilise such brushes in dynamos, and confirmed his monopoly. In this particular case the privilege was of no great value, for copper plates served the same purpose equally well, and did not fall under the patent.

In all cases we have contemplated up to now the advancement of manufacture was attempted by men who devoted their lives to a particular branch of industry, and were actively engaged in carrying it on. As it is to be expected, the subject-matter of their proposals has in most cases a solid foundation, meeting an existing want, or extending the application of known devices; for such men are well versed in the practical requirements of their daily work, and of necessity make themselves acquainted with all that is new to their own branch of industry. Nearly all the large establishments have nowadays a special staff of workers, who do nothing but investigate inventions or experiment with modifications of manufacturing devices and processes. In addition to these private investigators, most technical colleges undertake similar research, and accounts of their work are published in the technical journals of all countries, resulting in a rapidity of advance that could not be realised without the aid of our modern means of communication. A natural consequence of this mutual reaction on each other of many workers is the subdivision of labour, which is carried further every day, and makes civilised man increasingly dependent on his fellow-workers. At the same time, it is evident that the share of each worker in the advancement of his art, or in the introduction of useful novelties, must become smaller and smaller, as each step is at once made known to most of the persons concerned.

To an attentive observer it must be quite obvious that those people have the least chance in the race who are not well acquainted with the branch of industry in which they wish to introduce improvements, and who do not study the technical literature bearing on the subject. Contrary to expectation, these are precisely the people who clamoured for cheap patents, and who inundate the Patent Office with their inventions. In 1883, the cheap patents were at last granted, and the effect has been that the number of patents taken out which, during the 10 years ending 1882, was on the average 3,506 annually, has grown to 25,000 during the year 1893, their number having steadily increased ever since the new law was introduced. This class of inventors not only ignores what is already known, but they treat with very little respect the so-called details which have to be worked out before any proposals assume a practical shape. Unfortunately for them, it is the question how these details are to be carried out, which decides, in most cases, the fate of an invention, and a seemingly brilliant idea will often prove delusive because some small factor in the problem has been overlooked. In a similar manner they do not realise that the knowledge of scientific principles might be an assistance in their efforts, or if they study science at all they think they can acquire the necessary knowledge by a short study and without much trouble. Some of these inventors even go further, and claim that their ideas are genuine novelties in every respect, and that objections based on scientific reasons are only expressions of professional jealousy.

Poor Galileo is quoted as an example of a man whose ideas were in advance of his age, who was not appreciated by his contemporaries, and who has been proved to have been in the right by posterity. When a man brings this argument forward it is quite useless to quote the natural laws which make the carrying out of his invention impossible. He will gravely assure you that scientific men will have to reconsider the conclusions which are not in accordance with the new invention

Digitized by Google

and that they will find out the error of their ways. It would not be surprising if you thought that nowadays education is so universal, and the means of learning all about a branch of industry so easily attainable, as to prevent people from falling into the errors I am speaking about. But some examples of proposals seriously laid before my firm will convince you that a sanguine inventor is quite independent of college or of workshop, and that in this case, as in many others, truth is stranger than fiction. The extracts have been chosen from letters actually received over 10 years ago; for obvious reasons, all dates and names are omitted. About 14 years ago my firm fitted up the Royal Albert Dock with a system of arc lights, and not long after the following communication was received:

"Having studied the subject of the 'utilisation of natural forces for the purposes of electric lighting,' we have found a method, which is as cheap as it is possible. We understand that you have under your control the lighting of the Royal Albert Dock by electricity. For that purpose there are, we believe, four engines, to each of which there is an average of three men. As a matter of course, electricians and other operatives directedly connected with the production of light are omitted. Well, gentlemen, the result of our studies is that we have constructed a machine which will produce sufficient motive power to work as many electric machines as would be required to light the Royal Albert Dock and Victoria Docks for 16 continuous hours without expenses of coals, etc. Another decided advantage is, that two men are all required. The money simply spent in coals for one week to supply the steam-engines at present there would be sufficient to keep one of our engines or machines going for a month, including the expense of labour! It is with great pleasure that we submit this idea (to you in the first place) to be approved of or otherwise. Lack of funds prevents us as inventors from patenting our discovery, but if suitable arrangements can be made, it will be parted with on moderate terms. This is an invention the principles of which are simple, construction cheap, and mode of working easy. The machine can be constructed in nearly every town in the kingdom. The 'machine,' together with 'purchase' connected with it, may be easily patented; and, thus defended, the patentee may go to work without fearing any piratical attacks from others. There is a rough model of one of the machines in London, where it may be seen; as soon as this letter is satisfactorily answered, the address will be sent."

From the tone of the letter it is evident that the writers had some idea of business, and were prepared to make moderate terms with anybody who would help them to bring out their invention. This is not always the case, as the next example will show: "I believe I am in possession of a valuable idea to which electricity may be applied with enormous advantages, and if it succeed no doubt would be largely used. Having had the matter before one or two gentlemen who have made electricity considerable study, I may say that they are perfectly satisfied as to its success if properly carried out, and suggested my laying it before you with a view to an experiment. The machinery required would not consist of much. If you are disposed to assist me so as to ensure a proper experiment being made, I should, of course, give you the necessary information under secrecy, as, of course, if it turned out a success, I should like to patent it if possible."

No offer is made of a share in the profits in return for assisting in carrying out the experiments, most probably because such inventors have no idea of the difficulties attending experiments and their cost. The popular idea is that a truly great invention ought to be made on the lines that Prof. Hughes followed when he constructed the first microphone by the help of a matchbox and a few pieces of broken carbons. It is certainly true that a genius will accomplish much with apparently insignificant means, nevertheless, a good many experiments were necessary before a practical form of microphone was settled upon—but of these the general public knows nothing.

When I came to England in 1867 I made the acquaintance of one of our workmen, whose business it was to lacquer brass-work. He had the peculiarity of coming to his work only long enough to earn sufficient to keep him from starving; the rest of his time he devoted to the construction of a machine for generating power. He had been a lawyer of good standing in one of the minor German States, but unluckily for him he had a "mechanical turn of mind," which induced him to give up his practice and to come over to England, where he hoped to realise a fortune from his invention. In 1867 he assured me another fortnight's work would complete the machine, and a new era would commence in the world's history. In spite of all arguments, of all ridicule, and of all the disappointments, he continued working at this machine until he died about two years ago without being any nearer to his goal than he was 20 years ago. Other professional men have had peculiar views with regard to mechanical problems, as the next letter will show:

"I was yesterday in the Crystal Palace and saw what I believe was a multiplier of power. I have had a dynamo-electric magnetic apparatus working on the sulphuric acid and zinc system, and it has frequently occurred to me that if the gathered-up wire or power thrust into the machine could be increased to an indefinite extent it could be productive of wonderful effects. Now this appeared to me done in the machine I saw in the Palace, but it appeared to me the thing required was velocity and common use. I have made a diagram on paper of a pail of water turning a small waterwheel regulated by the tap in the pail. This would give velocity, but no power to speak of, but if this velocity could be communicated by a pair of hydraulic bellows, then power and velocity would both be gained. If the idea is feasible, and you would like to take it up, I would be glad to form a company to carry it out on any terms you may approve of. I cannot carry out the idea myself for three reasons: advancing age, defective money, and I am sorry to say, considerable laziness. I am a registered medical practitioner and a Crystal Palace season-ticket holder, and the reason I apply to you is because I have a friend in one of your employés named Mr. J— H—, although as I do not know his address, of course I could not communicate with him."

There are some cases where a really useful invention seems to lie within the grasp of the inventor, but his want of thorough knowledge of the subject stands in his way. From numerous examples of such failures I will only mention the following:

"For some little time back I have been considering the practicability of lighting railway carriages by electricity and procuring the electricity by friction on the wheels of the carriages when in motion, with an accumulator in each carriage, so that when the train stopped at any station the accumulator would have a sufficient storage of the electric fluid to keep up the supply for a few hours if necessary. This mode of lighting carriages would be a great economy to the railway companies, not only in oil but in labour, and it would be a benefit from its superior light. The electric light could also be used for the lamps in front and stern of the train, thereby showing the lights at a much greater distance than at present. Before applying for a patent for the application of the electric light, I would feel greatly obliged by you giving me your opinion on the same, and if you approve it, would you have any objection to join with me."

You know, of course, that train-lighting is being carried out successfully on these lines; only the accumulators are charged by a dynamo driven from the axle, instead of generating the electricity by friction as proposed. A very attractive scheme is unfolded in the next letter:

"I beg leave respectfully to submit to you a plan for constructing the wheels of steamboats, etc., on a new principle, and also to adopt the system in other propellers. The plan proposes to form a wheel having on its outer sides or periphery a powerful magnetic principle to act on the water with this power or friction as the wheels of an engine on the rails. The magnets may be of unlimited power so as to act (*sic*) the largest attractive force on the water, and the wheels may be constructed on any plan. The object is to obtain greater efficiency and speed."

Strange as this proposal may sound, the last letter which I shall lay before you surpasses it in originality and vigour of expression: "I am not a madman—I am not an inventor—nor am I a mechanic—but I have been thrown amongst engines, stationary, locomotive, and marine, a great deal. A simple accident has revealed to me the *modus operandi* by which steam can be generated with any degree of power and employed in the propulsion of vessels without the cumbrous details of boiler or steam-chest, etc. I do not go to some capitalist who may rob me of the thought—nor some other who would wish to clap me into an asylum as a dangerous lunatic—but to practical engineers like yourselves who can if my idea is the mere dream of a fool instantly annihilate it with practical objections. If you will permit me to call upon you—five minutes is all I want—if I cannot satisfy you that I have not wasted your time, I will submit to be kicked out of your premises."

All these letters were received by my firm within the space of two years, and a great many more could be found, without doubt, if a further search were made, as the stream of such letters has been flowing in uninterruptedly ever since I can remember. It is certain, therefore, that a numerous class of people exist who are under the impression that they can advance a branch of industry by suggesting ideas that are plausible to them, quite irrespective of the existing experience or of natural laws. As a rule very little is heard of them in public, because these ideas are seldom of any value, but if by chance an outsider makes a successful suggestion, the most is made of it, and the example is quoted by everybody as a proof that special knowledge is by no means required. My object to-night has not been to hold up to ridicule the endeavours of people who may be mistaken, but who worked hard enough and earnestly enough in many instances to deserve a better fate, nor do I wish in any way to discourage you from trying your hand at inventing, but I want to impress upon you the necessity of making yourselves throughly acquainted both with natural laws and existing practice. You cannot master your subject without careful study and hard work, but if you devote your time to the acquisition of this knowledge you will be well fitted to contribute your share to the progress of engineering.

THE LIME STREET EXCHANGE OF THE NATIONAL TELEPHONE COMPANY.

On Monday afternoon last a Press view was given by the National Telephone Company, Limited, of their new exchange in Lime-street, E.C., to which on last Bank Holiday the business of their East India-avenue exchange was transferred. The company have 30 exchanges in London, all connected with each other, and of these 10 are now using the twin-wire system, so that a complete metallic circuit is established. The remaining exchanges are also to be altered to this system, the introduction of which is no doubt due to the result of the report of the Parliamentary Joint Committee on Electric Power (Protection) Clauses, which virtually left telephone companies to protect themselves against earth or other currents.

The alteration which is being effected will no doubt prove gratifying to the subscribers of the system, and it is stated that the whole metropolitan area, which covers more than 600 square miles, will soon be working on the improved plan. The cost of the work is estimated at about £200,000.

The building in Lime-street was originally a warehouse, and has been adapted to its present purpose by considerable structural alterations. A new roof has been built, upon which is constructed an octagonal standard composed of 39 tubular iron poles. The poles are braced together with iron arms, and securely fastened to the outside walls by iron rope stays. The circumference of the standard is 190ft., and is capable of carrying 6,000 wires; besides this, provision has been made for leading in a considerable number of wires in cables, each cable containing 104 wires, equal to 52 subscribers. At present there are 2,050 subscribers connected with the exchange, besides 240 junction wires and private wires. The standard carries 2,300 insulators for open No. 18 phosphor bronze wires, apart from the wires in cables. From the roof the wires are led through cables to the test-room on the topmost floor, and are there attached to brass springs arranged in numerical order corresponding with the subscribers' numbers. It is here that the subscribers' lines are tested for faults, and the faults localised.

From the test-room the wires are led in a lighter class of cable into the switch-room which is on a lower floor. This room has been fitted with the latest and most approved pattern of multiple switchboards made by the Western Electric Company, of Chicago, and has been designed to meet the requirements of 7,000 subscribers. At present it is fitted for 3,000 subscribers, besides the necessary wires giving connections to other exchanges of the company, both in London and other important towns in the country—viz., Liverpool, Manchester, Leeds, Birmingham, etc. The switchboard is divided into numerous sections, every wire coming into the exchange being led on to the first section, and thence to the second, third, and every other section in the room, each of 3,000 subscribers' wires being attached to a separate spring jack on each section throughout the room. This, together with the necessary junction wires, involves the use of 73,540 spring jacks, and as each spring jack requires five wires to be soldered to it, there are in all, including the soldered connections to the indicators, over 500,000 soldered joints in the room, and the length of wire is over 800 miles. Two hundred indicators are brought on to each section, and four operators attend to a section. By a new arrangement, when an operator connects any two subscribers' lines, the indicator automatically closes. A third indicator is provided in order to signal to the operator when a subscriber rings his bell after finishing his conversation.

On the floor under the switch-room are provided a dining-room, kitchen, etc., for the operators. On the same floor is an engine-room for a Tangye gas-engine, which drives a dynamo for charging the E.P.S. accumulators which supply current for the working of the exchange.

The electric light has been installed throughout the exchange, current being obtained for this purpose from the mains of the City of London Electric Lighting Company.

WIRING REGULATIONS IN MANCHESTER.

By the courtesy of Mr. C. H. Wordingham, electrical engineer to the Manchester Corporation, we are enabled to reproduce the following wiring regulations drawn up by him for use in that city:

Internal Fittings.—The Corporation will not supply or fix any internal fittings except the meter and main fuses on consumers' premises. It is necessary that the wiring on consumers' premises should conform to certain conditions and tests, both for the protection of the Corporation and also for the protection of the consumer himself. The following provisions, however, are intended for the protection of the Corporation and of the whole number of consumers collectively, although they are incidentally beneficial to the particular consumers; but the Corporation will take no responsibility in respect of testing a consumer's premises for his own protection.

Terminals.—Electricity will be supplied, at the option of the consumer, at the pressure of 100, 200, 300, or 400 volts. Except by special arrangement, not more than 50 amperes may be supplied at 100 volts from a single pair of service terminals. When more current is to be supplied, the lamps or other consuming devices must be divided between different pairs of the five conductors. If this rule be departed from, there is danger that the pressure of the supply will not be so uniform as it should be. The installation must be divided up into circuits of not more than 50 amperes each, even when the current exceeds 200 amperes.

Cut-outs.—All conductors must be protected by double-pole cut-outs, which must be competent to cut off the current, if this exceeds the normal current by 50 per cent. It must be impossible for an arc to be maintained between the terminals of any cut-out.

Double-Pole Main Switch.—The contractor to the consumer must in all cases provide and connect up within 3ft. of the Corporation's double-pole fuse, or in such other available position as shall be approved by the Corporation's engineer or his representative, a double-pole quick-break switch of approved design.

Effectual Insulation of all Cut-out and Switch Covers.—It is essential that the covers, handles, or levers of all cut-outs or switches should be of porcelain or other non-conducting material, and any metal parts whatsoever likely to be touched by the hand must be effectually insulated from the electrical circuit.

Switches.—The switches must be so constructed that they do not heat with the full current; that it is impossible for them to remain in a position between full on and full off; and that it is impossible for an arc under any circumstances to be maintained on the switch.

Insulation.—Before connecting the premises of any consumer, the installation will be tested for insulation, and it will be tested from time to time to ascertain that the insulation has not deteriorated. The whole of the lamps or other consuming devices being connected to the conductors and all fuses being in, the insulation resistance between the whole system and earth will be measured after not less than one minute's electrification. The following conditions must then be fulfilled—viz., the insulation resistance for incandescent lamps shall not be less than 50 megohms, divided by the number of lamps fixed irrespective of their power up to 50 candles—that is to say, for installations of

	Ohms.
25 lamps the insulation resistance must be	2,000,000
50 ,, ,, ,, ,, ,,	1,000,000
75 ,, ,, ,, ,, ,,	666,000
100 ,, ,, ,, ,, ,,	500,000
200 ,, ,, ,, ,, ,,	250,000
300 ,, ,, ,, ,, ,,	167,000
400 ,, ,, ,, ,, ,,	125,000

When lamps of higher candle-power are fixed, their equivalent in 50-c.p. lamps will be taken as the number of lamps for the purposes of this test. In cases where the lamps are divided up into separate circuits, in order to comply with Rule 1, each circuit will be treated as a separate installation, provided that no part of it is in electrical connection with any other circuit before being joined to the mains. When buildings are wired on the three wire, four-wire, or five-wire systems the installation will be measured as a whole. The insulation resistance for arc lamps shall not be less than five megohms divided by the number of lamps fixed, for lamps taking current up to 10 amperes; for larger sizes their equivalent in 10-ampere lamps will be taken for the purposes of this test. The insulation resistance of any part of a motor which carries current, together with all leads, sliding contacts or metal work connected to the circuits of the motor, shall not be less than one megohm. If it is desired to use current for purposes other than those specified above, special conditions, which may be obtained on application at the Town Hall, will be enforced. In any case, whatever may be the number of incandescent lamps, arc lamps, motors, or other consuming devices, the insulation resistance shall not be less than 10,000 ohms, even if such an insulation resistance involves a higher insulation resistance per lamp or per motor than that specified in the above rules.

Termination of Service Conductors.—The Corporation's service conductors will terminate in a double-pole fuse supplied and fixed by the Corporation; this fuse will be placed as near as practicable to the outer wall of the building, but in cases where the consumer occupies elevated premises or premises at the back of the building (unless the back of the building abuts on a street in which mains are laid) the Corporation will run the service conductors into such premises, provided the consumer agrees to pay the cost of providing and fixing so much of the conductors and their protection as is within the outer wall of the building.

Entry of Service Pipe.—The hole in the wall for the admission of the service pipe must be cut by the consumer.

Service Pipe on Property other than Consumer's.—In cases where permission has to be obtained from owners of property to allow the service pipe to be carried through such property, it rests with the consumer to obtain this permission, and the owner of the premises will be required to sign an agreement indemnifying the Corporation from any damage that may arise from such portion of the service conductors being fixed within the building.

Service Main not to be Interfered With.—In no case will the Corporation on any consideration allow anyone but their own officials to run any portion of a service main or to make a connection of any description on the main side of the main fuse.

Position of Meter.—The Corporation will provide a suitable meter, for which a rent, varying in amount according to the size of the meter, will be charged, and they will fix this meter free of expense in any convenient position, as near the main fuse as possible.

Digitized by Google

Sealing of Meter.—The consumer must provide conductors long enough to reach to the meter, and must efficiently protect them from mechanical injury, but they must be affixed to the meter by the Corporation officials, and the seals of the meter must on no account be broken by the consumer.

Fittings, etc., to be Approved.—All wiring, electrical fittings, and appliances of every description, situate on any premises intended to be used in connection with the supply of electricity from the Corporation must be approved by the Corporation's engineer before the installation is connected with the electric conductors belonging to the Corporation; and in order to avoid risk of work done having to be altered, samples should be submitted to the engineer for approval before the work is begun. Consumers should communicate with the Corporation before the wiring of their premises is begun in order that the position of the service pipe may be decided upon, otherwise alterations may have to be effected.

Conductors.—All conductors must be of tinned copper, must be covered first with a layer of pure rubber, then with a layer of vulcanised rubber of approved thickness, and the whole must be protected with braiding or taping rendered impervious to moisture. All conductors must further be efficiently protected either by incombustible tubes or by hard wood casing. The use of flexible conductors, except for wiring fittings and pendants, must be avoided, and in all cases where it is used the sanction of the Corporation's engineer must be obtained. In no case must the insulation resistance be less than 600 megohms per mile when tested after one minute's electrification, the coil being immersed in water. Contractors must satisfy the engineer that the wire will actually pass this test.

Flexible Conductors.—When twin flexible wire is used it must be insulated with first, a layer of pure rubber and then a layer of vulcanised rubber. No flexible wire insulated with silk or cotton only will be passed.

Wires to be Stranded.—All conductors having a greater sectional area than that of a No. 16 standard wire gauge must be stranded.

Gas Fittings.—No gas fittings may on any account be adapted to electric lamps unless they are efficiently insulated from the gas-pipes at the point at which they are attached to the same, and their use, even when so insulated, should be avoided as far as possible.

Alterations in Number of Lamps.—When it is desired to add to the number of lights already installed, notice in writing must be sent to the Corporation of the consumer's intention to do so, and the new work must on no account be connected on to the old until it has been inspected and passed by the Corporation's engineer or his representative. In cases where it is intended to diminish the number of lights fixed, notice in writing must be sent to the Corporation.

Temporary Work.—In no case will work of a temporary nature be permitted to be connected to the mains.

Staples.—Staples must not be used under any circumstances, nor may flexible wire be threaded through metallic eyes. The capping of all casing must be secured by screws and not by nails.

Arc Lamps.—Arc lamps must be insulated as a whole from earth, and must be so fixed that it is impossible for them to swing into contact with any metalwork connected to earth. When fixed in positions exposed to the weather, the conductors joined to them must be provided with specially thick insulation, which must be further protected by a covering of lead, and every care must be taken to avoid abrasion of the insulation.

Motors.—All motors must be provided with a switch and starting resistance to be approved by the Corporation's engineer, and to be such that in no case can the current through the motor, when at rest, exceed 10 amperes, or increase by greater steps than 10 amperes at a time as the starting resistance is cut out. Each motor must further be provided with a double-pole switch.

Consumers Responsible for Fittings.—The Corporation do not undertake any responsibility for the efficiency and proper execution of any work by a contractor on a consumer's premises. The inspection and insulation test is made for the purpose of the Corporation only.

Building Occupied by More than One Tenant.—In cases where a large building occupied by several tenants is wired, either of two courses may be adopted at the option of the consumers—viz.: (*a*) The conductors may be run from the premises of each tenant to some convenient point in the building to be approved by the Corporation's engineer. In this case a separate main fuse for each tenant and a separate meter will be provided and fixed by the Corporation, the usual meter rent being charged in each case, and the tenants will be regarded as separate consumers dealing direct with the Corporation, and each must fill up an application form for his own lights. A double-pole main switch must be provided and fixed by each tenant, as in the case of ordinary consumers. (*b*) The building as a whole may be wired and the conductors of the several tenants tapped off wherever desired. In this case a double-pole fuse and double-pole switch must be provided and fixed by each tenant where his conductors branch off from the main wiring of the building, and a meter will be provided and fixed on the tenant's premises by the Corporation. A master meter will also be fixed for the whole building. The Corporation charge rent for all meters fixed, and will send their meter reader to read them, but the account will be rendered on the reading of the master meter only, the tenants not being recognised as separate consumers. In this case the proprietor of the building must apply for the whole number of lamps required by the tenants. He will be furnished with the readings of the meters, and he must himself recover from the tenants the various amounts for the quantity consumed, the Corporation accepting no responsibility in the matter whatever.

LIGHTING INSTALLATIONS.

In our last issue we reproduced a paper on this subject read by Mr. H. A. Henderson, member, before the Northern Society of Electrical Engineers. We now give a report of the discussion:

Mr. Eidsforth: The point which struck me most forcibly was the system of testing joints. Of course in installation work proper I have not had much experience, but I used to have a great deal to do in the cable line, and at that time joints were tested under water, and it seems to me to be a great mistake that this is not the case now. I don't know the system which is at present in use, but Mr. Henderson said he had tested something like 500 installations, and he seems to have got hold of a good few bad joints out of that number.

Mr. Claremont: The only thing in Mr. Henderson's paper which has struck me is the paragraph, or few words which he said about the consumer having to pay high prices for fittings unless he goes to a manufacturing firm. This should not be the case if the manufacturer is sufficiently fair to allow discount to the trade only.

Mr. H. Wooler: The only thing I have to find fault with in the paper is the remark made about Manchester being in a better position than any other town for the supply of current, having the alternative of wiring either on the three or five wire systems. Mr. Henderson said that owing to having two or three different voltages to select from they should be able now to supply current cheaper than anywhere else, and he mentioned the Free Trade Hall as a case in point. I very much doubt that. We all know that the higher the voltage the less the current, or should be; but in Manchester, where they have a fixed contract, and charge you for the whole of the lamps connected, and possibly you do not use half of them, it becomes rather arbitrary, and they certainly have not had a very small bill at the Free Trade Hall.

Mr. C. S. Northcote: I should like to correct Mr. Wooler in one or two of his statements. He points out that at the Free Trade Hall the charge for current is high. This is on account of their being wrongly advised. I am rather surprised that he should draw attention to the fact. The installation has never been properly metered, and, furthermore, when the Manchester Corporation meter such installations more satisfactorily than they are at present there should be less grumbling. There is nothing, in my opinion, in the paper about the saving of current to the consumer, but a suggestion as to the price of installations. I beg pardon, it is mentioned, but I should call it an error.

Mr. Wooler: The only point I can make out by using the three-wire or multiple-wire system is that you can afford to put in larger cables.

Mr. Northcote: I may say that I quite agree with Mr. Henderson's remarks *re* the sub circuit system. I myself know that very little work has been done up to the last few months on this system. When the electric light first came into use the tree system was mostly employed, but undoubtedly that has been altered in Manchester lately; most buildings are now wired on the multiple system, with sub-distribution boards for alternate circuits. I think Mr. Henderson is right in remarking that this is a good system, and should be more generally used. With regard to Mr. Claremont's suggestion as to manufacturers maintaining discounts, I think it is a very great pity that we cannot all combine together and get the prices raised instead of cutting them down so. I have a case in point which I happen to know of, where a large manufacturer of a certain article in which we were interested and supplying to consumers, quoted us £500 for certain goods. I was asked our price, and on mentioning this was shown a telegram from the makers direct allowing, say, 5 per cent. off this price. Such instances as this make things very awkward sometimes.

Mr. Thomas: There is only one point in the paper which I should just like to mention, and that is the action of cement on indiarubber; it seems to have a very strange effect. For instance, if you put a wire into a bucket of water you get no leakage through it at all, but if you put that same wire upon a damp wall, whether there are any joints in it or not, you get a leakage through it after it has been up possibly only a few hours, and I never had this explained. Perhaps some of the gentlemen in the cable line will be able to assist us in this matter.

Mr. Fawcus: I have myself noticed considerable action having taken place with casing fixed against enamelled bricks, and there can be nothing in enamelled bricks that can attack the wires, but there seems to be some kind of cement or other used for attaching these enamelled bricks. We have had several cases of wires being completely eaten through.

Mr. George Broughall: The only point which I should like to mention is the price at which work is at present being put in. It appears to me that the lasting power of installations lies in the quality of the material which is put in, and it is to me wonderful, at prices which I know several installations have been put in, how they have passed inspection at all. Of course some of them may pass inspection when first installed and new, whereas, perhaps, in a few months they would not pass another inspection of the work. Then what about the consumers? Most likely they have to take out a portion of the work, if not all, and go to the expense of having it done over again. I think everything possible should be done to improve the quality of work, instead of bringing it down, as is the case at present, with the low prices that are going. It seems to be the rule nowadays to take the lowest tender and

Digitized by Google

cut down the prices. If good work is to be put in, I think a fair price ought to be paid.

Mr. A. Eckstein: I have just one thing to mention, and that is that Mr. Henderson seems to think that fitting manufacturers should do installation work, whilst cable manufacturers should not. Now, I think this is the other way about. He seems to think that the reason why fitting manufacturers ought to do installation work is because their clients cannot get fittings at reasonable prices. I think if any manufacturer does installation work it should only be on one supposition, and that is, that more justice could be done to the quality of his manufactures by putting in the work himself, but not at all on account of price.

Mr. J. Conolly: With reference to the action of cement upon indiarubber, which was mentioned a little while back, I have heard very often of this, but have never seen any cable that has been affected in that way. If any gentleman has any samples by him, I should like very much to see them; I would try and find out the cause of the trouble. Mr. Eidsforth asked the reason why joints in electrical installations were not tested by immersion in water the same they are in telegraph work? I may say that I do not think this feasible at all; I think it is impossible to test a joint in a strange building with all the complexities of electrical fittings, etc., in the way; as a matter of fact, I think it is altogether out of the question. The main point is to try and improve the condition of the wireman at present employed, and I quite agree with Mr. Henderson that as a rule he is entirely incompetent.

Mr. E. H. Nisbett: With the present method of house wiring, joints are undoubtedly a weak point, but I do not see that water-tight joints can be made at all, and I do not think that any house joint could be tested under water, whether it was intended for a damp place or dry. Undoubtedly with some of the joints that are put in at the present time there is going to be trouble in the future. If pure rubber only lasts a few years, and vulcanised rubber, say, 15 or 20 years, what is going to happen? What is the good of putting in wire to last 20 years, and putting in joints that will only last a tenth of that time? I think it is for the vulcanised cable manufacturers to advise something, and help out the contractors in this matter. We are thinking of doing something very shortly in the matter of lead-covered cable for house wiring.

Mr. Fawcus: Has any gentleman present had any experience with Andrews's system of concentric wiring?

Mr. Nisbett: I saw something of it when I was second engineer to the City Company on several installations, and there are one or points that are perhaps worthy of attention. One is that owing to the iron return in Andrews's system, the self-induction with alternating currents is very great, and the resistance of the return conductors is in consequence very much higher. Mr. Nisbett then went on to criticise one or two more points of Andrews's system.

Mr. Broughall: I should like to mention one other point, and that is: that as the weak points in installations are apparently in the joints, I think the number of joints should be reduced as far as possible, and I quite agree with Mr. Henderson that the only way to do this is to run the wires back to distributing boards. This may cost a little more money in the first instance, but at the same time I think it would be a great saving in the long run.

Mr. Andrew: May I make a suggestion to the effect that if periodical inspection were made of electrical installations the trouble might be very much reduced, as it seems to me that if the contractor had in his mind the possibility of his installations being inspected at any time he would probably be more careful in putting in good work in the first instance.

Mr. Henderson, in reply, said: Mr. Eidsforth has suggested that in his opinion joints should be immersed in water for testing purposes. This would undoubtedly be a very good thing if it could be done, but for housework it is almost an impossibility. I am afraid that very few joints at present made would stand any test of the kind at all. The obvious thing to do is to vulcanise the joints, and I am given to understand that a very simple and expeditious method of vulcanising joints has lately been brought out. It is undoubtedly a very important point, as joints certainly have more to do with bringing down the insulation resistance than anything else. Mr. Claremont said something about the price of fittings which I did not quite catch. I think he said that manufacturers of fittings should supply them at a moderate price, provided they took care to allow trade discount, but I think there are very few firms who allow trade discount to private individuals; perhaps there are a few exceptions. Mr. Wooler has made reference to the amount of current used at the Free Trade Hall, but I think I am right in saying that with regard to the Free Trade Hall there is an actual saving of current through having adopted the five-wire system. Probably the reason why the Free Trade Hall seems to consume more current than it should is because it was never properly metered. It was metered in earlier days by two Thomson meters on the outers, which was practically of no use whatever. Now, a five-wire meter has been adopted, but this does not seem to be of any practical use, as it seems to register whether the lamps are being burnt or not. Mr. Thomas alluded to the action of cement on rubber insulating material. I think that it is perhaps not altogether the action of cement. I think you would find that you got the same result if you embedded the wire in any kind of plaster or concrete, or anything else of the kind. Very often it is due to the electrolytic action through exposure to moisture. Mr. Fawcus has asked for instances of corrosion with enamelled bricks. I have a very vivid case before me where we had a meter which got an earth leakage—that is to say, we got 200 volts to earth. The meter was fixed on a pine board, and the board was fixed on enamelled bricks. It had been fixed some six or eight months, with probably an average current of 1½ to 2 amperes leakage to earth, and when we came to inspect it we found the board almost destroyed, and behind the board when taken down we found that the glazed surface of the bricks was entirely destroyed and broken up, and just the ordinary brick surface left beneath. Mr. Broughall has made some allusions to the price at which work is going. I think he said that a fair price ought to be paid for fair work, and this is quite right, but I am afraid we have many contractors who put in good work and good material, but at ridiculous prices, obviously in order to get established. Mr. Eckstein has said that cable manufacturers should do installation work in preference to fitting manufacturers. Considering that two-thirds of the capital outlay goes in any case to the cable maker, I think it is only fair that the fitting maker should be in a position to pull back something on the one-third that is his share. Mr. Conolly spoke of improving the condition of the wireman amongst other things, and this I consider a most important point. Why not have schools, etc., for teaching the work, and then we might possibly be able to get hold of some really qualified men. His other remarks I have already spoken about. I quite agree with Mr. Andrews's remarks with regard to periodical inspections, and in future in Manchester this will be carried into effect, I believe. Once in six months each installation in the town will be inspected, tested, and a record kept of anything broken down, insulation resistance, etc.

Mr. Fawcus (the chairman): I am sure that we have obtained some good from Mr. Henderson's paper, although I had hoped for a far more animated discussion upon some of the points than we have had. One or two things have been brought out which are undoubtedly of importance, but I consider that one of the most important probably is (to contractors at all events) the low prices at which work is going at the present time. We are constantly hearing of jobs being taken, mostly by young firms who are endeavouring to get established, as Mr. Henderson said, at prices at which it is simply impossible to make it pay. I think we should all endeavour to keep prices up as much as possible. If a man is not pinched in prices he is not likely to get any bad work. As to the question of joints, of course we cannot help getting any number of bad joints in the best installations, as we cannot possibly follow wiremen through every joint that is made, and if we are pushed, as Mr. Henderson mentioned, we are bound to reduce practically our supervision, as we have got more men on, and we have to take men on some of whom we know nothing at all about. This probably is the most fruitful cause of bad joints. I quite see Mr. Nisbett's point as to the uselessness of vulcanised rubber if we make pure rubber joints, but, of course, in house work it is impossible to carry fire about the place. Until we get higher prices we can hardly hope for these refinements in workmanship. In conclusion, I would like to move a very hearty vote of thanks to Mr. Henderson for his very interesting paper.

Mr. Henderson: I hoped to have had a little more discussion on the subject, but, nevertheless, I would just like to add that, with regard to the system of vulcanised joints for houses, Mr. Fawcus said that it would be impossible to carry fire about on installation work, but I think the new process I spoke about does away with this entirely; I believe it is not necessary to have any heat. I presume we shall be hearing more of it in the electrical papers; if it can be brought to any state of perfection, it will no doubt be a very good thing. I beg to thank you very heartily for the vote of thanks and kind reception of my paper.

THE RECENT EXPLOSION IN THE CITY.

Our readers will perhaps have had their attention sufficiently directed by the daily Press to the somewhat remarkable accident that occurred last Saturday week at the corner of Budge-row and Cannon-street, when a horse passing along the roadway was killed by an electric shock, and a number of foot passengers also received shocks or were injured by two explosions which followed soon after in a couple of junction-boxes situated at this point. In order to put the facts on record, however, and so that our readers may afterwards follow such remarks as we find occasion to make both now and when the Board of Trade inspector's report on the accident is published, we append herewith an abstract of the evidence giving salient points of a technical nature brought out at the official enquiry instituted by the Board of Trade.

The enquiry was opened on Monday last at Winchester House, and being of a public nature there was a large attendance. Major Cardew, R.E., the Board of Trade inspector in charge of the investigation, presided over the enquiry; Mr. R. W. Wallace (instructed by Messrs Ashurst, Morris, Crisp, and Co.) appeared for the City of London Electric Lighting Company, Limited; Mr. Russell Griffith for the aldermen and City Commissioner of Police; and Mr. Baylis for the City Commissioners of Sewers.

George Clarke, the first witness called, said that on the 10th inst. he was driving a mare attached to a brougham into Budge-row from Cannon-street when suddenly the animal fell forward and then rolled over on its side. He had the reins in his hands at the time, but felt nothing until he alighted. As soon as his feet touched the ground he felt a severe shock pass through his whole body. He saw no smoke and heard no noise. After feebly struggling for about four minutes the mare died, but before it expired it foamed and bled at the mouth and nostrils. Since the explosion he had been unable to do any work, and was at the present time in the doctor's hands. Replying to **Mr. Griffiths**, witness stated that he did not drive over any metal plate. It was about 1 o'clock when the accident occurred, and he was driving very carefully, as the wood roadway was wet.

James Hutchings, a warehouseman, said that he was standing on the loophole at 21, Budge-row, where he was employed, looking

Digitized by Google

into Cannon-street, when he saw the mare fall down. He hastened to render what assistance he could, but when alongside the animal he experienced a shock which nearly knocked him down. He placed his hand on the ground to save himself from falling, and for the moment he thought his arm was broken. There was a rumbling sound audible under the ground, and shortly afterwards the explosion in Budge-row occurred. The force of the explosion blew the lid of a street box, situate near the late offices of the Liberator Society, about 2ft. off the ground. In reply to **Mr. Griffiths**, he said he neither touched the horse nor the brougham. After recovering a little from the shock he did all he could to warn people from coming near the spot. In answer to **Mr. Wallace**, witness was unable to say which explosion happened first—that in Walbrook or that in Budge-row. In answer to **Mr. Baylis**, witness said that after receiving the shock he returned to his office and superintended the loading-up of some goods on to a railway van.

C. J. Willy, a postman, said that while passing along Cannon-street on the day in question he saw several people standing round a horse which had fallen down. In trying to pass on he trod on the iron cover of a street box in Budge-row, and imme diately received a shock through the whole of his body which nearly threw him to the ground. While standing subsequently talking to some people in Walbrook he saw pieces of flagstone fly up into the air. One fragment struck him on the finger, and some iron hit him on the toe. His mouth was filled with concrete, and he was hurled across the road. Replying to **Mr. Griffiths**, he said he was rendered almost insensible. He did not recollect smelling any gas at the time of the explosion, but the pavement was much disturbed, and the cover of the box was blown to pieces. In answer to **Mr. Wallace**, he said he was now doing his ordinary work.

Several other witnesses gave similar evidence.

A. Haslett, mining engineer, 64, Cannon-street, said that when on his way to keep an engagement in Walbrook he noticed a boy suffering from a slight shock near where the horse was lying. He told Police-constable Bradley of the danger he suspected, and while he was speaking to him the explosion took place in Budge-row. He saw the lid of the box lifted about 12in. or 14in., and then apparently fall down into the hole again. This was followed by reports like three guns going off, one after the other. A blue flame shot out of the manhole near where he was standing, followed by dark smoke. He felt sure it was not a gas flame. In his opinion the explosions in Walbrook and Budge-row were simultaneous. In hurrying to the pavement he received a shock in his left leg, the pain from which extended up one side of his body. He was taken to Guy's Hospital, and there treated for partial paralysis but he had not fully recovered yet from the effects of the shock In answer to **Mr. Wallace**, witness said he had never suffered from rheumatism.

Thomas Cowley, carman, of Barnsbury ; **A. Neal**, an errand boy ; and **Police-constable Bradley**, gave evidence of a corroborative character.

F. Withers said he was in his father's shop at the corner of Walbrook on the 10th inst., about 1 o'clock, when he heard a subterranean noise, followed by an explosion which blew in one of the basement windows of his father's shop and damaged the iron of a sunblind. He received no shock.

H. Freeman, assistant to the last witness, said that between 11 and 1 o'clock on the day of the accident he noticed several times a smell like that of burning indiarubber when going into the basement of the shop. It was not overpowering. There was a similar smell in the basement when the explosion took place.

Mr. Griffiths then put in reports of previous explosions of gas in electric light manholes which had taken place in the City—one in Great Tower-street, another opposite St. Paul's-churchyard, and a third at the crossing of Creed-lane, near Ludgate-hill. In the first case it was stated that the lid in the manhole was blown 20ft. into the air, and that a man was injured.

District-Inspector Eve said that two witnesses of the explosion in Walbrook, named Loveland and Moody, were still too unwell to attend the enquiry.

Mr. David Cook, manager and engineer of the City of London Electric Light Company, Limited, handed in plans of circuits and diagrams giving the connections of the main which broke down in the City, etc. He said the primary cause of the accident was the crossing of two high-pressure cables which were being tested and put to work for the first time. One of these cables was for the supply of current to the Watling-street transformer station, the other for the Milk-street transformer station. The Milk-street cable was inadvertently put into the Watling-street terminals at Bankside, while the Watling-street cable was laid with its inner conductor touching the lead covering of the third inner cable. For convenience, the Watling-street cable was made alive by current from the transformer station. When the signal was given, the man at the transformer station switched on. The inner of the conductor, as already explained, was against the lead covering of another cable, and, therefore, the inner of the whole high-pressure system was put to earth, throwing an unusual strain upon the insulation of the primary mains. The company's cables were all tested to a much higher pressure than anything that could be put upon them by a mistake of this kind ; but, unfortunately, a rubber cable supplying the Benetfink transformer station broke down in the junction-box at the corner of Cannon-street and Budge-row. The cause of the breakdown appeared to have been due to mechanical abrasion of the outside covering. When the mistake was discovered the attendant at the transformer station cut the cables out, but before this was done the leak in the junction-box had developed into a short-circuit. This fired some gas which was in the conduits and blew up the cover of the box at the corner of Walbrook, some 60ft. distant, and also moved the box cover opposite 20, Budge-row. Since the explosion occurred at St. Paul's-churchyard his company had had men constantly employed searching for gas in their conduits. Four times since March last they had written to the gas company complaining of gas leakages in Cannon-street, within 100 yards of the spot where the explosion took place, and since January last they had written to the gas company 88 times calling their attention to similar leakages all over the City. He wished to call the attention of the Board of Trade in the strongest manner to the question of the responsibility of the gas company in respect of these explosions.

Major Cardew said the gas company had not put in any appearance, and he did not think he could go into that. No one had detected any smell of gas in the present case.

Mr. Cook replied that he merely wished to point out the difficulty his company had in keeping their conduits free from gas. He had not a word to say against the gas company, but the men they sent to look after leakages did not always wait till they found them. Hitherto it was thought that the safety of the public was assured by systematic inspection, but to increase that safety he should recommend his directors at their meeting the next day to provide a complete system of ventilation of the conduits at a cost of about £2,000.

The enquiry was then adjourned until the following day, when **Mr. Cook**, continuing his evidence, said the company's high-pressure cables were all concentric and were tested to a very high pressure.

Major Cardew, referring to the witness's statement on the previous day, that the breakdown appeared to be due to a mechanical abrasion on the outside covering of a cable, asked whether the cable was bent sharply at that point.

Mr. Cook replied that as far as he knew it was not bent very sharply, but men had been working a good deal in that box drawing low-pressure and other cables, and his opinion was that they had rubbed the cable against the edge of the iron pipe. The cable which broke down was supplied under a specification which required it to stand the test of 5,000 volts pressure between the inner and the outer, and 5,000 volts between the outer and the earth. Immediately the accident occurred he had all the other cables tested to a very high pressure, and found they were all sound. The accident was not an absolute short-circuit, but an arc. There was no ventilation of the street boxes where the explosion occurred, but there were a number of telephone tubes, which provided a current of air between the boxes, and they had been frequently inspected.

Major Cardew enquired if there were any appliance to indicate that the pressure had risen to a dangerous extent upon the outer conductor?

Mr. Cook answered that there was a statical voltmeter, showing the pressure between the outer and the earth, at the company's station, but it did not give any notice of the state of the pressure automatically. It had now been found better to put in armoured cables, and he had given orders for covering all the parts of the cable not laid in iron pipes and passing through the street boxes with several layers of copper strips, securely connected to both ends of the iron pipes. This must not be taken as an admission that they had been very much at fault for not doing so earlier, as this was only one of the points to be learnt by experience.

Major Cardew asked the witness if, with his present experience, he had come to the conclusion that it was not sufficient to trust to the thickness of indiarubber insulation between a highly-charged cable and an iron street box.

Mr. Cook said his experience tended to show that high-pressure alternating-current mains should be concentric and protected by a strong metal covering throughout their whole length. A lead-covered cable drawn through an iron pipe would answer as well.

Major Cardew enquired if the witness did not think a steel armouring outside the lead, if close and continuous, would be a desirable extra precaution?

Mr. Cook replied that they must not adopt too many extra precautions He did not think it was necessary, but if the Board of Trade made such a recommendation they would carry it out. Continuing, he said a man went round constantly to examine the street boxes. They had no ventilating pipes running up the sides of houses. In reply to **Mr. Wallace**, the witness said everything that could be thought of was done to prevent the percolation of gas into the conduits of the electric lighting company. It was his opinion that if the City Commissioners of Sewers permitted his company to ventilate the explosive mixture of gas and air which went into their conduits by replacing some of the guard posts at the corners of the streets with hollow posts, some arranged to take the air down and some with an up draught, there would be no further danger to the public by explosions. No one had any idea of the money his company had spent to make their system safe. They supplied more high-pressure current than any other electric lighting company in the world, and they did it in a very densely-populated area. As the consequence of these unique circumstances, problems which had not been solved elsewhere were constantly presenting themselves for solution to the City of London Electric Lighting Company. He had no doubt, however, that a far greater number of people would be maimed and killed by slipping on orange peel in the streets of London than were ever likely to be injured or killed by electricity. He had not heard of any consumer or other person not connected with the works being killed since the inauguration of the undertaking.

Mr. G. F. L. Foulger, chief distributing engineer of the Gas-light and Coke Company, said that owing to certain evidence given on the previous day he appeared to state that there was no gas in the boxes which exploded or in the vicinity. Immediately

Digitized by Google

after the accident the ground was examined by means of searching rods and Ansell's leak detectors, but no trace of gas was found, and the experiments were repeated the next day with a like result. Although he could not say this was an infallible means of detecting gas, yet under a hermetically sealed pavement, as in this case, it was bound to do so. Replying to **Mr. Wallace**, the witness said he thought the ventilating scheme suggested by Mr. Cook a very bad one, as owing to the height of the posts a person might strike a match against them with disastrous results. He considered a better plan would be to use their arc posts, which were about 20ft. high, for the purpose. These posts should be filled up with earth or sawdust. To prevent the gas firing back, a 1½in. or 2in. ventilating pipe should be carried up them with an outlet to the atmosphere at about 10ft. high.

General Webber, C.B., said the whole question of the ventilation of the street boxes in the City had been gone into by him carefully, following on many years' experience both in connection with telegraph street boxes and those of other electric light companies in London and elsewhere. The prevention of the entrance of gas into the boxes appeared to be the one measure essential to public safety, seeing that more than one House of Commons committee had declined to allow street boxes to be ventilated by attachments to private houses. He did not dispute for one moment that ventilation by means of inlet and outlet pipes would be an excellent thing if they were arranged so as to secure a strong current of air to pass up and down; but he was sure the very next best thing was to construct the boxes gas-tight, with glazed bricks or other suitable materials, and close all the unused pipes by wooden plugs or tarred yarn, or something of that kind. He thought it should not go before the public from this enquiry that these street boxes, even without ventilation, were a source of danger, because they were not so, except in the most unusual circumstances. That was the conclusion he had arrived at, and it was particularly the case if the boxes were constructed in an air-tight manner themselves and the passages between box and box closed by plugs.

Mr. W. G. Wagner, analytical chemist, said that on the previous day he took samples of air contained in the electric lighting company's street boxes at the corner of Walbrook and at the corner of Dowgate-hill. In the latter box he found approximately 12 per cent. of coal gas, but none in the Walbrook box. As there was communication between the two boxes he thought there would also have been coal gas in the Walbrook box, but there was not.

Mr. J. Lister, outdoor superintendent to a firm of electrical engineers, said that about 11 o'clock on the 10th inst. he noticed a strong smell of gas near the street box against the old offices of the Liberator Building Society.

The enquiry was then adjourned until to-day (Friday).

LONDON COUNTY COUNCIL AND ELECTRIC LIGHTING LOANS.

At Tuesday's meeting of the London County Council the following report was submitted by the Finance Committee:

We have again to report upon the question of the periods for the repayment of loans obtained by vestries and districts boards for electric lighting. It may be well, first of all, to remind the Council of the history of this question and of its present position.

In 1891 the Vestry of St. Pancras applied to the Council for loans of £10,000 for the purchase of a site and £60,000 for the construction of electric lighting works, the repayment of the former to be spread over 60 years and of the latter over 42 years. At that time the Council had power to lend to vestries for 60 years for the purchase of land, but only for 30 years for the erection of buildings. The Council, being anxious to meet the views of the Vestry, sanctioned the borrowing of the latter sum for 42 years, and as it could not itself lend for that period, resolved to apply to Parliament for powers to advance money for electric lighting purposes for periods not exceeding 50 years. This power was applied for in 1892 and obtained, but it was understood as between the Treasury and the Council that the period to be actually fixed under the provisions of the Act should be determined as freely as if the extended period had not been named by the Act.

On July 25, 1893, we recommended the Council to sanction and make a further loan of £15,400 to the Vestry of St. Pancras, repayable in 42 years. The sanction was given, but the Vestry did not take up the loan from the Council. On January 30, 1894, the Council considered a further application by the Vestry for the loan of £30,000 (including the above-mentioned £15,400), but on this occasion, after consideration of the whole subject, and of the views expressed by the Treasury, we recommended that the loan should be granted to the extent of £29,700 (on condition that the previous sanction of the Council to the borrowing of £15,400 should not be further acted upon), and that the repayment should be restricted to various periods according to the life of each portion of the works. After discussion in the Council this report was withdrawn. We again reconsidered the whole matter, and brought up a report to the Council on February 12, 1894, recommending that the repayment of the whole should be spread over 25 years. An amendment to substitute 30 for 25 was lost, and our recommendation was ultimately adopted.

On June 26, 1894, the Council considered an application by the Vestry of Hampstead for sanction to a loan of £24,400. We recommended that the sanction should be granted subject to the repayment of the whole sum being spread over 25 years, but the Council in this instance substituted 42 for 25 years.

After this decision of the Council, we felt bound to adopt in all cases the period of 42 years for initial electric lighting works, and therefore recommended the Council to advance to the St. Pancras Vestry for 42 years the sum of £14,300, the difference between the £29,700 sanctioned on February, 12, 1894, for 25 years, and the £15,400 on July 25, 1893, for 42 years. The Council adopted this recommendation, and application was accordingly made to the Treasury for approval of the advance by the Council. The Treasury replied (see letter dated July 28, 1894) practically to the effect that they could not sanction the advance of this loan by the Council for so long a period as 42 years, and we therefore directed our attention to the question whether any new proposal could be made which would be acceptable to the Treasury and which the Council might be willing to adopt.

The contention of the Treasury was that no period should be granted which was disproportionate to the life of the works, and in order to arrive at a definite understanding on that point we carefully investigated, with the assistance of the engineer, the question of the durability of each portion of the work in greater detail than had hitherto been done. We were advised that the following division of the work in the St. Pancras case might be taken as being fairly accurate: £3,800 for meters and connections lasting five years; £4,000 for batteries lasting eight years; £2,000 for arc lamps and cooling apparatus lasting 10 years; £13,000 for boilers, covered mains, etc., lasting 15 years; £24,000 for engines and dynamos lasting 20 years; £33,000 for culverts and bare copper mains lasting 40 years; £9,000 for buildings lasting 60 years; £10,500 for land; total 99,300.

We thought that it might fairly be argued that as Parliament extended the maximum period for electric lighting purposes from 30 to 50 years, it was intended that at any rate some portion of the expenditure should be spread over 50 years. On the other hand, it could not be considered right to spread over 50 years expenditure of so short-lived a nature as meters and apparatus of that kind. We therefore came to the conclusion that the Council might be advised to adopt two periods for loans for the initial cost of electric lighting—viz, 50 years for all expenditure on land, buildings, culverts, bare copper mains, and patent royalties, and 20 years for expenditure for all other purposes.

The comptroller, by our instructions, communicated with the Treasury suggesting these terms and stating the considerations which had led us to decide upon them, and the Treasury has, with only a slight modification, agreed to our proposal. We present copies of the correspondence with the Treasury. We think the Council would desire that a definite agreement should now be arrived at between the Treasury and the Council as to the terms for which these loans are to be sanctioned and made, and as the Treasury has signified its consent to the more favourable proposals of the committee, we recommend the Council to pass the following resolution: "That the periods of repayment of all loans for the initial cost of electric lighting undertakings be limited as follows: for land, buildings, culverts, bare copper mains, and royalty licenses relating to such purposes, 50 years; for all other purposes, 20 years."

This proposal was agreed to by the Council.

THE PROPOSED PACIFIC CABLE.

The question of the projected Pacific cable is much exercising the mind of Sir John Pender, who has unburdened himself to representatives of the Press.

When referred to the statement, which was reported in our last issue, that Lord Ripon contemplated calling another inter-colonial conference on the subject, Sir John said that he was in favour of the extension of submarine telegraphy whenever and wherever it could be shown that it was necessary and desirable. In this instance, however he could not but think that a good many foolish ideas were obtaining currency. The subject was one to which he was giving close attention at the present time, and he did not desire to make any statement which might be subjected to misconstruction. At the same time, looking at the matter from the point of view of an investor, he said they had a striking illustration in the Atlantic of the need to act with caution. The cables in the Atlantic were not making anything like an adequate return on the amounts spent in their construction.

In the course of another interview, Sir John Pender said there was an impression abroad that he was opposed to a Pacific cable. He was not opposed to the extension of submarine telegraphy wherever it was required and wherever it could be used for the development of commerce, and if the colonies and Great Britain decided to have a cable by the Pacific no doubt that cable would eventually be laid. But in the present depression of trade in the colonies he doubted if they would be disposed to commit themselves to additional outlay for submarine cables, when at the present moment they possessed all the advantages which submarine cables could give them. There was a sort of craze at the present time over this Pacific cable, and an attempt had been made to show that it was an absolute necessity, and that the want of the cable was rather retarding the progress of the colonies. He thought that as a telegram between Canada and Australia, or the Cape of Good Hope, *vid* London, occupied only about two hours in transit, the laying of a Pacific cable immediately was not imperative, and considering that the amount of money involved would be about two millions, or, if the cable were duplicated, four millions sterling, he believed that the shrewd and wise men who were at the head of the respective Governments would seriously consider the cost before they agreed

Digitized by Google

to expend such a large sum of money unless they could see that such an expenditure would largely benefit the trading interests of the empire. But if the Governments determined to have this additional cable, he believed that his company was in a position to undertake the work on better terms than any other company could do it, and he would warmly co-operate with those Governments to extend the system without damaging the companies which, they all admitted, had given them such a satisfactory and beneficial telegraph service.

TENDERS FOR THE PACIFIC CABLE.

The *Ottawa Citizen* of the 10th inst. gives the following additional information on this subject: "As announced some days ago, a number of tenders was received at the Department of Trade and Commerce in response to the call for proposals for the laying and maintenance of the Pacific cable.

"The Hon. Mr. Bowell postponed the opening of these tenders until the arrival of Mr. Sandford Fleming and Mr. Mercer, of the British Colonial Office, the cable commissioners from Hawaii. The commissioners returned Wednesday evening, and yesterday the opening and examination of the tenders took place in the office of the Minister of Trade and Commerce. Six definite proposals were sent in They are made by the following companies:

"Francis A. Bowen, 3, King's Arms-yard, London.
"The Telegraph Construction and Maintenance Company, 38, Old Broad-street, London.
"Messrs. Siemens Bros., 12, Queen Anne's-gate, London.
"The Fowler-Waring Cable Company, 32, Victoria-street, London.
"W. T. Henley's Telegraph Works Company, 27, Martin's-lane, Cannon-street, London.
"The India Rubber, Gutta Percha, and Telegraph Company, 106, Cannon-street, London.

"These are the leading cable manufacturers and cable-construction companies of the world, and their proposals are said to indicate a thorough examination of the whole great project.

"The offers are of the most satisfactory character. They apply to each of the eight routes proposed, and in every case are below the estimates of Mr. Sandford Fleming already made public. As the offers are accompanied by very elaborate details which will require to be examined carefully, compared and reported upon in order to submit full information to the various Governments interested, the Hon. Mr. Bowell said he did not deem it advisable to make the figures public at present. It is said, however, that the proposals are in each case very much more favourable than was anticipated by those who discussed the matter at the recent Colonial Conference, and on the whole they are regarded as completely removing every obstacle which had been urged against the feasibility of the Pacific cable."

COMPANIES' MEETINGS.

COUNTY OF LONDON AND BRUSH PROVINCIAL COMPANY, LIMITED.

The annual general meeting of the above Company was held at Cannon-street Hotel on Monday, the Right Hon. D. R. Plunket, Q.C., M.P., occupying the chair.

The Chairman, in moving the adoption of the report, which was printed in our last issue, said he might congratulate the shareholders on the position of the Company, and on the encouraging nature of the immediate future. There had only six months passed since the reconstruction and capitalisation of the Company had put it into a position really to go to work. They had now made considerable progress. and while within the county of London their preparations had advanced as quickly as was consistent with the exercise of care and prudence, their experience in the more distant districts where they were working had been fortunate even beyond their expectations. With reference to the county of London, the contracts with the Brush Company and the Electric Construction Company, which were mentioned in the prospectus under which they made their first issue of capital last spring, were being executed, so that before that time next year they would have a supply of generating plant equal to the service of 90,000 incandescent lamps. They had obtained at moderate prices two admirable sites for the erection of generating stations for their London business, one of them, for the north side of the river, on the Regent's Canal basin, and the other, for the southern side on the bank of the Thames, near Wandsworth. At both of these they obtained the economy of water carriage for their coal, and the advantage of an abundant supply of water. The directors intended to lay not only sufficient mains to provide for their immediate requirements, but also a large number of spare pipes, into which, without further breaking up of the roadway, additional cables could be drawn when they became necessary. There was a large and increasing demand in the metropolitan districts which they had acquired, while the progress of the Bournemouth Company had been very rapid and the plant had been increased At Dover their prospects were extremely hopeful, while at Windermere they had entered upon an interesting and what they believed would prove to be a very profitable enterprise. They had secured the use of the water power where the River Leven flowed out of the lake, and they proposed to utilise this to supply the electric light to such of the towns in the neighbourhood as chose to avail themselves of the Company's offers. They had also made and would continue to make applications for provisional orders for other places within and without the county of London, and applications had been made to the Company for financial assistance in carrying out electricity supply undertakings in various parts of the country. They intended, as far as they could, to follow the wise policy of management of the City of London Electric Lighting Company.

Mr. A. Thompson seconded the motion, which was agreed to.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY, LIMITED.

The twenty-eighth ordinary general meeting of the shareholders of the Western and Brazilian Telegraph Company, Limited, was held on Friday last at Winchester House, Mr. W. S. Andrew in the chair.

The Chairman, in moving the adoption of the report, said that compared with the half-year ended June, 1893, the increase of words transmitted was 628,295—almost a large business in itself. If this business had been done under normal conditions, they would have been able to pay a dividend of 3½ per cent. instead of 1 per cent. for the half-year, and they would see that their only trouble was the question of exchange, in which he hoped there was going to be an improvement. Referring to the prospect of their concern being taken over by the Government, he said that it was undoubtedly the fact that Brazil had power under their concession to acquire their lines. As they understood it, there was an official report on the part of a Government Commission, recommending the Government to purchase the undertaking, and although they felt that this proposal was made just as the clouds were beginning to pass away, they could not but recognise that with the affair in its own hands the Government would derive large financial advantages. The recommendations in the report would be submitted to the Chambers, and if they were approved a resolution would probably be passed authorising the Government to negotiate and purchase.

The adoption of the report, having been seconded by **Lord Richard Browne**, was agreed to.

GENERAL ELECTRIC POWER AND TRACTION COMPANY, LIMITED.

An extraordinary general meeting of this Company was held on Wednesday at the Cannon-street Hotel, Lord Egerton of Tatton occupying the chair.

The Chairman said he had stated at the last meeting that some reorganisation of the Company was necessary in view of the large loss of capital as shown in previous balance-sheets, and that the directors were giving serious consideration to the subject. It was agreed that the realisation of the Company's assets should be proceeded with as soon as possible, and since that time the directors had made considerable progress in that matter. The manufacturing department had been transferred to the Acme and Immisch Electric Works, Limited, in consideration of £12,500 in fully-paid shares of that company, and the electric launch business had been taken by the Immisch Electric Launch Company, Limited, in consideration of £8,965 in fully-paid shares. In the opinion of the Board, the further realisation of the assets could best be carried out under voluntary liquidation, and that he had now to propose. With regard to the copper works, when they were first started they promised to be very remunerative; but the fall in the price of copper had entirely altered the conditions. He concluded by formally moving that the Company be wound up voluntarily under the provision of the Companies Acts.

Mr. Immisch seconded the motion, and remarked that the Company was started originally with the idea that electric traction was coming to the fore, and his firm sold its lucrative business to the Company entirely for shares; so that he was a considerable sufferer.

Messrs. Benjamin Nicholson and Dunn expressed the opinion that the business must have been very badly managed to have entailed such a heavy loss, and another **Shareholder** suggested that a committee should have been appointed to go into the affairs of the Company.

Mr. Garcke, who explained that he represented a large interest, and had been called in to consult with the Board, said a large amount of the capital lost was represented by shares paid to Messrs. Immisch. The companies which had taken over the manufacturing and launch businesses had been created specially for the purpose, and this Company owned the shares. He thought the directors had acted in the best interests of all concerned in recommending the liquidation.

The motion was ultimately agreed to *nem. con.*

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Madrid.—Tenders are invited by December 8 by the Spanish Government for the construction of a telephone system at Santa Cruz, Teneriffe. Tenders are to be sent to the Ministère d'Outre Mer, Madrid.

York.—Tenders are invited by the directors of the North-Eastern Railway Company for telegraph apparatus and for telegraph wire and line stores. Forms of tender may be obtained on application

Digitized by Google

to Mr. Graves, Telegraph Department, York, and tenders must be sent in to the secretary at York by Tuesday, 27th inst.

Blyth.—The Cowpen District Local Board (Blyth, Northumberland) invite tenders for the efficient lighting, by electricity or otherwise, of the lighting area within their district for a period of seven or ten years respectively, commencing from August 15, 1895. A plan of the district can be seen and further information obtained at the Surveyor's Office, Commercial-buildings, Waterloo, Blyth. Tenders, endorsed "Lighting," to be sent to Mr. Robt. T. Guthrie, clerk to the Board, not later than December 20.

Hampstead.—The Vestry of St. John, Hampstead, invite tenders for wiring the buildings in the stoneyard, Lithos-road, Finchley-road, N.W., for the electric light, including the supply and fixing of all cables, casings, and electrical fittings; but not lamps. A form of tender, with copy of specification and a description of the general routes to be followed, may be obtained at the office of the vestry clerk, Vestry Hall, Haverstock Hill, N.W., upon the deposit of £1. 1s., which will be returned on receipt of a *bonâ fide* tender. The various buildings at the stoneyard may be inspected on presentation of an order to do so, signed by the vestry clerk. Tenders must be delivered by Thursday, 29th inst.

RESULTS OF TENDERS.

Portsmouth—The contract for the complete equipment of the electrical and physical laboratories of the Portsmouth Corporation has been awarded to Mr. Robert W. Paul, 44, Hatton-garden, E.C., the price being £477.

St. Pancras.—The Electricity Committee of the Vestry have accepted the tender of the Electric Construction Company, Limited, for switchboard, motors, transformers, electrical instruments, etc., at King's-road station, the amount being £3,489. 11s. 8d.

BUSINESS NOTES.

Milford Haven.—The electric light has been installed in St. Catherine's Church.

Gainsborough.—The Albert Theatre is receiving an installation of the electric light.

Rochdale.—It is probable that the public buildings will be lighted by electricity.

Tuam.—A company proposes to apply for an order for the electric lighting of Tuam.

Western and Brazilian Telegraph Company.—For the past week the receipts were £3,181.

Dunrobin.—Dunrobin Castle, the seat of the Duke of Sutherland, is to be lighted electrically.

Monmouth.—Combination fittings for gas and electric lighting are to be installed at the post office.

Appointment.—A pupil is wanted in the central station of the Exeter Electric Light Company, Limited.

Hanley.—The Electric Lighting Committee of the Town Council are considering the advisability of providing additional plant.

Conway.—A scheme is under consideration for using the water power of the Conway for electric lighting and power purposes.

Pontypool.—The Pontypool Electric Light and Power Company, Limited, are applying to the Board of Trade for a provisional order.

Bradford.—Mr. W. C. Dixon has been elected chairman and Mr. James Kay vice-chairman of the Gas and Electricity Committee of the Town Council.

Mullingar.—A company is going to apply for powers to introduce the electric light. The Town Commissioners have given their approval to the scheme.

Portishead.—The chairman of the Local Board has informed them that he has received two or three offers by private companies to light the district electrically.

Glasgow.—Councillor Ure has been appointed convener and Councillor Shearer sub-convener of the Gas and Electric Lighting Committee of the Town Council.

St. Bride Foundation Institute.—This institute, situated in St. Bride's-lane, E.C., which was opened on Tuesday by the Lord Mayor, is to be lighted electrically.

Stockport.—The Guardians of the Stockport Union have decided that the workhouse to be erected at Stepping Hill, Hazel Grove, is to be lighted by electricity.

Aberdeen.—Mr. W. F. Price, late of the Preston National Electric Supply Company, has been appointed, from among 50 candidates, as assistant to Mr. Ruthven-Murray.

Ashington.—The new Grand Hotel. New Hirst, Ashington, which has just been opened, is lighted throughout by electricity. A Crossley oil-engine and a Charleton dynamo are used.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 18th inst. amounted to £881, as compared with £553 in the corresponding week of last year.

Randall's Phonautograph Company, Limited.—This Company has been registered with a capital of £25,000 in £1 shares to manufacture and deal in phonautographs, or phonographs, or other apparatus.

Salford.—Mr. Alderman Mottram, who has been chosen mayor, in referring to local improvements which are being carried out, mentioned the system of electric lighting, which he said would soon be completed.

Folkestone.—The new Lighting Committee consists of Alderman Salter and Councillors Pursey, Payer, Jones, Thompson, Holden, and Mercer. There seemed to be no desire on the part of any of the councillors to be placed on this committee.

Kensington.—Application is to be made to the Board of Trade in the coming session of Parliament for a provisional order to extend the area of the Notting Hill Electric Light Company, Limited, so as to include a part of the parish of St. Mary Abbotts, Kensington.

Bishopsgate.—The electric light installation at the Bishopsgat Polytechnic, which was opened on Saturday by Lord Rosebery, has been carried out by Mr. A. H. Wood, of Westminster, and the fittings have been supplied by Messrs. Verity and Sons, of King-street, Covent Garden.

Snowdon Mountain Tramroad and Hotels Company, Limited. This Company has been registered with a capital of £70,000 to construct a tramroad from Llanberis, to a point near the summit of Snowdon; to erect an hotel near the summit, and to construct and maintain tram and railroads, telegraphs, etc.

Paddington.—The Local Government Board have agreed to the sealing of the contract by the Paddington Guardians, without advertising for tenders, with Messrs Spagnoletti and Crookes for the supply of electric light wiring for the male wards and administrative block at £145 and £115. 10s. respectively.

New Firm.—A new firm of electrical engineers and contractors has been started at 22, Charing-cross, S.W., by Messrs. J. A. Russell, A I E.E., and R. F. Barrett Lennard, A.I.E E Mr. Russell was recently with Messrs. J. G. Statter and Co., Limited, and Mr. Lennard with Messrs. Latimer Clark, Muirhead, and Co.

The Snowdon Railway.—According to present arrangements, the first sod of the Snowdon electric railway will be cut on the 5th prox. Mr. Assheton Smith, the owner of the land, who extends to the promoters all facilities for the successful carrying out of the scheme, will be asked to perform the inaugural ceremony.

Turbines.—Messrs. Carrick and Ritchie, Waverley Engineering Works, Edinburgh, send us a catalogue of their improved turbines, in which particulars are given of the Waverley turbine in its various designs, of Ritchie's new double-gate turbine, of the Girard turbine, of a combined turbine and dynamo, and of jet waterwheels.

Leslie and Co., Limited.—This Company has been registered, with a capital of £50,000, to acquire as a going concern the business of builders, contractors etc., as hitherto carried on under the respective styles of Leslie and Co., and Aldin Bros. and Davies, and to carry on business as builders and contractors, electric light contractors, etc.

Mansion-Lighting.—Among the more important installations Messrs Drake and Gorham have in hand at the present time may be mentioned Londonderry House, for Lord Londonderry, who entrusted the same firm with the lighting of Wynyard Park two years ago. A large number of lights is being put in, and the current will be obtained from the outside supply.

Storage Battery Litigation.—We are requested to state that "The Electrical Power Storage Company, Limited, has commenced a suit for infringement of the Swan patent, and has issued a writ for injunction against the Chloride Electrical Storage Syndicate, Limited. The other defendants are Messrs. Mather and Platt, Limited, and Dr. John Hopkinson, F.R.S."

J. G. Statter and Co.—The Bedford Engineering Company, this week, petitioned for the winding up of J. G. Statter and Co., electrical engineers. Mr. Theobalds said negotiations were pending for the sale of the company's business on terms which would be very favourable, and he therefore asked that the petition should stand over. Mr. Justice Williams: Very well. Adjourned for a month.

Smithfield Market—The new installation of arc lamps round the Smithfield Markets of the Corporation of the City of London is being supplied with current from the City of London Electric Lighting Company, and one of Heathman's patent wheeled extension ladders is used for the recarboning. This ladder, although it reaches 32ft. high, is easily handled by one man, and thus the labour bill is kept at the minimum.

Windsor.—The Town Council have, after considering Mr. Shoolbred's report and the information supplied by the town clerk, decided to apply for a provisional order. The following streets comprise the compulsory area—namely, High-street, Thames-street, and Peascod-street, as far as the junction with Victoria-street, Windsor, and High-street, Eton, as far as the gateway entrance to Weston's yard in Eton.

Woking.—The Sanitary Committee of the Local Board reported that at their meeting a letter was read from Messrs. New and Mayne in reference to the delay caused by inability to obtain the bases, and also a telegram stating that the same would be sent on the 9th. The clerk was instructed to write, informing them that a piecemeal installation would not be accepted, and pressing on them the necessity of using the utmost despatch. The report was adopted.

Coventry.—The General Works Committee have presented to the Town Council a report on the delays which had arisen in the equipment of the tramways for electric traction, and recommended that notice be given to the proprietors of the tramways requiring the tramways to be equipped within three months The report was approved. The Town Council announce that they will be able to supply current to private consumers about January next. The price to be charged is 6d. per unit.

Digitized by Google

Marylebone.—The St. Marylebone Vestry have received a letter enclosing an account for £10 for fixing electric lighting fittings in Trinity Church, the rector of which suggested that this expense should be borne by the Vestry; also that in future the Vestry should pay at least the same amount for the maintenance of the electric light as they had paid in the past for the gas burners displaced. The letter, which was from the churchwarden of Trinity Church, was sent to the Church Committee.

Moss Side.—The Local Board have received a letter from Messrs. Fowden, Newton, and Varey, solicitors, applying for the consent of the Board to make an application to the Board of Trade for a provisional order for the construction of tram lines through the district, commencing at Brook's Bar and going along Upper Chorlton-road and Barlow Moor-road to Didsbury village. The method of traction proposed would be either gas motor or electricity. The General Purposes Committee of the Board will meet a deputation of the promoters shortly.

Bournemouth.—The Corporation have accepted the offer of the Bournemouth and District Electric Light Company to supply current to the Winter Gardens at 25 per cent. reduction in cost. This is in consequence of the report of the borough engineer, which was confirmed by Mr. E. Matthew Lacey, consulting electrical engineer, proposing a scheme for the Corporation to supply their own current by which a saving of £150 per annum was shown. Mr. E. Matthew Lacey also reported on the proposed lighting scheme for the pier and pleasure grounds.

Llandudno.—A special meeting of the Improvement Commissioners has been held to consider the advisability of applying to the Board of Trade for a provisional order authorising the local authority to supply their district with the electric light. The following resolution was passed: "That application be made to the Board of Trade to grant to the Improvement Commissioners a provisional order authorising them to supply electricity within the whole of the urban sanitary district of Llandudno, and that a committee be appointed to-day with full power to act in carrying out the same."

Colwyn Bay.—Mr. J. Roberts has stated at a meeting of the Local Authority that a private company was applying for powers to light Colwyn Bay by electricity. If a private company got the provisional order they would do as they liked. He thought that Authority should follow the example of Llandudno. He did not want that Authority to deal with the electric supply, but if the brilliant light was to come to Colwyn Bay he proposed that the Board have the power to make terms with a company, and that they therefore apply for a provisional order. Mr. J. Porter seconded, and it was carried.

Southwark.—The surveyor (Mr. Norrish) has read, at the meeting of the St. Saviour's Board of Works, an application from the National Telephone Company asking for power to lay cables in the parish. The route they proposed went right through the whole of the new asphalte footway in Southwark Bridge-road, in which they proposed to insert no fewer than 13 test-boxes. The electric lighting company and the Postal Telegraph Department had already laid mains and boxes in these footways, and the surface of the footways themselves would, he said, if this application be granted, soon be composed of little else than covers to test-boxes.

Royal Electric Company, Montreal.—Messrs. Coates, Son, and Co. are authorised by the directors of the Royal Electric Company, of Montreal, to receive at their offices, 99, Gresham-street, E.C., subscriptions for £120,000 4½ per cent. debentures at par. The debentures will be redeemed to the extent of £6,000 per annum by annual drawings of 105, commencing April 1, 1896, but the company reserves the right to redeem at any time on six months' notice at 110 the whole of the debentures not previously redeemed by drawings or purchase. The prospectus states that "the authorised capital of the Company is 1,500,000dol., and the paid-up capital is 1,000,000dol., upon which quarterly dividends at the rate of 8 per cent. per annum have for some time past been regularly paid."

Epstein Accumulators.—The Epstein Electric Accumulator Company, Limited, of 21A, Blythe-road, West Kensington, inform us that in order to cope with the increasing demand for their accumulators, they have taken new and extensive works at Milton, in Staffordshire, where their plant to the extent of 600 h.p. will enable them to quickly execute even very large orders The company are in a position to give their customers the benefit of the greater facilities for manufacture which the new works offer, and they have therefore materially reduced their prices. The history of the Epstein accumulators, which were first manufactured in England about four years ago, presents an uninterrupted record of success, and the company have recently again introduced important improvements in them.

Dock-Lighting.—The entrance to the Cessnock Dock, Govan, was lighted by the electric light for the first time last week. The lights are two in number, and are placed one on each side of the entrance to the new graving dock, at present under construction They are each of 4,000 c.p., and are carried on poles at a height of 50ft. above the quay wall. The electrical energy is supplied from a dynamo and gas-engine within the shed at dock entrance. The dynamo is of the Faraday type, and is driven by an Acme gas-engine, made by Bailie Burt The installation has been designed and carried out by the Faraday Electrical Engineering Company, Limited, of Govan, under the supervision of Mr. M'Whirter, their engineer, and to the specification of Mr. G. H. Baxter, mechanical engineer to the Clyde Trustees.

Dublin.—A start is about to be made with the construction of the electric tramway which will run between Haddington-road and Dalkey. Within the past few days Mr. J. Clifton Robinson, C.E., managing director of the company, who will act as electrical engineer of the works during their construction, has arrived from London, accompanied by Mr. J. Winslow, C.E., constructing electrical engineer, and Mr. August Kreuss, the tramway contractor. The new line will consist of eight miles of double track. The works will be commenced in a month, the contractor undertaking to complete the construction and electrical equipment of the entire system by May 1 next. The outlay will be about £120,000. The company will arrange the Ball's Bridge depôt as a power station, and the cars will be lighted by electricity.

Bath.—The Town Council have received a report from the Lighting Committee which referred to the recent failure of the electric light. The Council have accepted an offer made by the company to supply the required extra lighting by the street arc lamps at the rate of ½d. per lamp for each continual quarter of an hour they are alight. The company is to be offered £10 per month for increasing the lighting for half an hour per day from the present time to the end of February, 1895. The Mayor on Thursday last week issued a notice that the city would be in darkness that night, as it was thought that neither the electric light company nor the gas company would be able to maintain their supply owing to the floods. The warning proved correct as far as the gas company was concerned, but the electric light company rose to the emergency, and by dint of working all day up to their waist in water the men at the station got matters into such a satisfactory condition that the electric current was supplied as usual. Mr. Metzger, the engineer to the station, can be congratulated on the manner in which he coped with most remarkable difficulties.

Morecambe.—A committee of the Local Board reported that a certificate had been read of the medical officer of health that a certain building in Edward-street and Union-street, Morecambe, used for the manufacture of gas causing effluvia, the trade wherein was carried on by the Morecambe Electric Light and Power Company, Limited, was a nuisance and injurious to the health of the inhabitants of New-street and Edward-street in the district. It was unanimously resolved that the authority do direct John Bond, surveyor, for and on behalf of the authority, to make complaint before a justice, in order that the persons by whom the trade complained of is carried on may be summoned to appear before a court of summary jurisdiction to enquire into the complaint, and to proceed therein according to the provisions of the statute in that case made and provided. When the minutes of the Sanitary Committee came up for confirmation the Chairman said he wished to produce notices from two householders complaining of the electric light nuisance. Mr. H. Baxter thought that the Board had now an opportunity to take up the matter. The medical officer had not previously reported anything that could be made out to be a complaint, and he hoped that the matter would now be dealt with effectually. Mr. Bennett said that no time should be lost. The minutes of the committee were confirmed.

Worcester.—Upon the re-election of the Selection Committee, at a meeting of the Town Council, Mr. J. Millington moved a resolution instructing the Selection Committee to nominate a special committee to take entire charge and control of the electric work at Powick, and also all matters connected with electricity in the city, and that such committee should consist of seven members. Mr. Millington remarked that there was a vast amount of work to be done in connection with the electrical works, and there would have probably to be weekly meetings for the next year or two before the scheme got thoroughly to work. They had now spent £52,000 on the scheme, and the cost of extensions of mains which would come up at the next meeting of the Council, would bring the expenditure up to what he always said it would be, £60 000. In reply to Alderman Hill, Mr. Millington said he proposed that the business of the special committee should include the management of the accounts of the electrical department. Mr. Blackford suggested the desirability of a special rate for the electric light, in order that the citizens might appreciate the profit or loss on the enormous expenditure on the scheme. The Mayor pointed out that this did not bear upon the question of the appointment of a special committee, and Mr. Chaplin said that committee would consider the suggestion. Mr. Millington's proposition was agreed to.

City and South London Railway.—The receipts of the Company for the week ended November 18 were £972, against £882 for the corresponding week of 1893, or an increase of £90. The total receipts for the current period of the present half-year amount to £17,691, as against £16,473 in the corresponding period of 1893, an increase of £1 218. "Increases of from £50 to £100 per week, the *Financial Times* remarks, "have been regularly reported of late by the City and South London Railway. They might not look much in the Brighton market, but on a three-mile line like the City and South London they mean a good deal more than meets the eye. They represent on last year's traffic a growth of 10 per cent., and foreshadow a moderate addition to the ordinary dividend. But that is only by the way. Very much more important developments are in view. As the directors intimated in their last report, experiments have been made with a view to substituting car-motors for the locomotives hitherto used. It has been proved on the Liverpool Overhead Railway that such motors work cheaper than separate locomotives, and a still more valuable consideration for the City and South London is that they occupy less room. By adopting them the Company will be able to add a fourth carriage to their trains, and proportionately increase their carrying power at the busy times of the day. Another easy means of swelling their revenue would be to introduce two classes of fares, as at Liverpool.

Digitized by Google

Many City passengers would rather pay a penny extra for a little better accommodation, and we understand that the Company is likely to be memorialised to that effect."

Radcliffe.—The Electric Lighting Committee of the Local Board have reported that at a meeting of the committee held on the 15th ult. the chairman stated that he and Mr. R. Walker had had an interview with the Earl of Wilton's agent with reference to the purchase of a small plot of land in the Mount Sion-road, and that the only promise they could get was that it should be leased to them at 1½d. per yard, or sold at £600 per acre. Mr. Bennett waited upon the committee and advised with reference to the limits of the area of supplying, the compulsory area, and various other details of the scheme necessary to be inserted in the provisional order. It was resolved that the area of supply shall be the whole of the area included within the district of this Local Board; that the streets within which the distributing mains shall be laid within the period of two years shall be Blackburn-street, Stand-lane to corner of the New-road, Water-street to the canal bridge, Spring-lane to the railway bridge, Church-street to the railway bridge; Sion-street to the railway bridge and Whittaker-street; that the lists of streets not repairable by the inhabitants at large which may be broken up by this Board under the order shall be the whole of the streets in the district which are not repairable by this Board, the bridges of the Lancashire and Yorkshire Railway Company, and the bridges of the Manchester, Bury, and Bolton Canal, owned by the Lancashire and Yorkshire Railway Company. It was also resolved that the charge for current be 8d. per Board of Trade unit, with a minimum charge of 10s. per quarter. A long discussion was opened by Mr. Brooks as to whether the electric light would be taken down to Radcliffe Hall, and it was understood that as soon as ever practicable the mains would be laid to the extent of the Board's electric lighting boundaries.

Cardiff.—On Friday afternoon last preliminary trials of the electric light installation were made under the superintendence of the representatives of the engineers to the scheme and members of the Lighting Committee. The Town Council have announced that after that date they were prepared to supply current to the public. The first circuit was switched on about four o'clock by the chairman of the Lighting Committee (Councillor Vaughan), who was accompanied by the Mayor (Alderman P. W. Carey) and Alderman Jacobs, and subsequently the other three circuits were tested right along the streets in which the lines have been laid down—namely, Queen-street, Castle-street, High-street, St. Mary-street, Custom House-street, the top part of Bute-street, the Hayes, and St. John's square. A considerable number of houses and shops is being fitted with connections. The subject of extending the electric light installation beyond the limits of the present area was briefly discussed at a meeting of the Cardiff Lighting Committee on Tuesday, under the chairmanship of Councillor Vaughan. Councillor Riches strongly urged that a broad and comprehensive view should be taken by the committee of their electric lighting undertaking. If it were to become popular and remunerative, it would have to be placed within the reach of a much larger constituency than at present. The Borough Engineer (Mr. W. Harpur) agreed with Mr. Riches. He remarked that in a comparatively small town like Derby no fewer than 90,000 lamps were being supplied, although the light had only been in existence there for seven months. Councillor Riches and the Mayor said the experience of Manchester and Dublin was favourable to the suggestion to develop the scheme at Cardiff. It was understood that the borough engineer will draw up an estimate of and specifications for an extension of the light to the houses in Cathedral-road, Newport-road (as far as Clifton-street), Castle-road, and Richmond-road. The Borough Engineer stated, in reply to Councillor Riches, that he would be prepared to put the electric light into the Aberdare Hall in the course of three weeks. Mr. Massey said the Engineers' Institute, which is now electrically lighted from Lord Bute's mains, will be served at once from the Corporation central station. The Mayor said the opinion prevailed that the glass of the street arc lamps was too dense. Mr. Massey said the lamps were of the type seen by the sub-committee in Victoria-street, London, and, being deemed the best, they were selected. Councillor Riches suggested that the upper part of the glass, above the point of combustion, should be of transparent glass, the lower part to remain opaque as at present, to obviate a dazzling glare. In this way he thought the light would be more diffused. It was agreed to make the experiment.

Proposed Electric Tramway at Acton.—The Joint (Works and Electric Lighting) Committee of the Hammersmith Vestry reported to the Vestry last week as follows: "That with reference to the West Metropolitan Tramways Order, 1887, which authorises the use of electric or mechanical power on the tramways in this district, subject to the consent of the local and road authorities being obtained, your committee have carefully considered the application of the London United Tramways, Limited, for the consent of the Vestry to the use of electric traction on the line from Shepherd's Bush to Acton. The system proposed to be adopted by the company is the overhead-wire system. Your committee are informed that this system is already in full service in the most fashionable streets and boulevards in various cities. The system admits of the use of improved and electrically-lighted cars run at an accelerated pace and at more frequent intervals with safety and comfort. The company also propose to give the Vestry the free use of the standards for the purpose of carrying arc lamps for electric lighting. A considerable number of your committee have visited the system in working order at Havre, and are of opinion that the reconstruction of the Uxbridge-road line presents an opportunity which would be advantageous to that portion of the parish. Your committee therefore recommend the Vestry to give its consent to the use of electric traction on the tramways in Uxbridge-road, subject to such terms, conditions, and safeguards as may be considered necessary by the Vestry, and subject to the provisions of the Overhead Wires Act, 1891, and the by-laws of the London County Council under that Act." A report was then read from Mr H. Mair, the surveyor, who in the course of his remarks stated from enquiries made, including one from the Mayor of Havre, that although the electric installation at the outset was viewed with considerable apprehension, the result of the working has now merited unqualified approval, and on no account would a return to the old mode of traction be tolerated. Since the inauguration of the electric system the fares had been considerably reduced and the traffic has been greatly augmented, notwithstanding which the company have thereby been placed in a more satisfactory state. He therefore recommended the Vestry to grant the permission asked for, subject to such terms and conditions as the Vestry think desirable. Mr. T. Chamberlen, at the meeting of the Vestry last week, moved the adoption of the report. He referred in high terms to the success of the electric tramway system in Havre. He hoped there would be no difficulty about giving the company a good lift, and the company, he believed, would do all they could to assist the Vestry. If the company got the consent of the London County Council, it would do much to help Uxbridge road out of a slough of despond. Mr. Morrison seconded the motion, which, after further discussion, was passed unanimously. A motion was also agreed to urging the London County Council to take into favourable consideration the application of the company.

Taunton.—An enquiry has been held by Colonel Hasted, an inspector of the Local Government Board, in respect to an application made by the Taunton Town Council for permission to borrow a loan of £5,000, for the purpose of making certain extensions to the electric lighting of the town. The following are the particulars of the works intended to be carried out by means of the £5,000:

No. 2 sub-station in St. James's-street.			
Cables	£827	14	9
Laying cables and making connections	123	7	5
Two 30 kilowatt transformers and switches	261	16	0
Altering building for transformers	58	10	0
Instruments and fittings	68	1	0
Incidentals	90	0	0
or, say, about	£1,450	0	0
No. 3 sub-station at East-gate.			
Cellar to be constructed	1,500	0	0
Coal-shed, weighing machinery, and other works at depôt	300	0	0
New boiler, large engine, etc.	1,750	0	0
Total..	£5,000	0	0

The Town Clerk made the usual statement respecting the position of the town, and mentioned that the Town Council asked for a loan originally of £16,000 for the purchase and arrangement of the works, but £15,000 was granted, the balance amount for working capital not being allowed. The works had been under the Corporation for about 12 months, and were working satisfactorily, the balance-sheet showing a much improved position. Of the present loan of £5,000, only £2,000 would be spent at first, the rest being held over until No. 3 sub-station at East gate was required, which would be about 12 months hence, or as soon as the hospital authorities decided to light that institution with electricity. The Borough Surveyor explained that No. 2 station in St. James's-street would be placed in a cottage which they proposed to lease, and would be connected with the depôt by means of a high-tension cable, and it would then send off low-tension cables over the bridge as far as the George Inn, back to North-street and the Parade, and then back to the central depôt. No. 3 sub-station would be similarly connected with the central station by means of a high-tension cable along Harmony-row, and would give out the current by low-tension wires along East-reach, East-street, and Silver-street. It was also contemplated to provide a new coal-shed, with weighing apparatus and also new boilers, dynamos, a large engine, etc. Councillor Potter pointed out that the new boiler would not be obtained until No. 3 sub-station was put down in East-gate. The whole of the extensions were recommended by Dr. Fleming for economical reasons before they were adopted by the Town Council. The inspector afterwards looked round the works and the sites of the proposed sub-stations.

Yarmouth.—The Electric Lighting Committee of the Town Council have submitted lengthy reports. The substance of these was as under: The committee ordered the lighting of 134 gas lamps to be discontinued. The surveyor was authorised to engage an engine-driver, lamp-trimmer, and switchboardman who have been working at the station. He made complaint that none of the plant for private lighting had been delivered, and customers who had wired up their premises could not be supplied with current. The town clerk was directed to ask Mr. Preece to call the attention of the contractors to the penalties under their contract. In reply, Mr. A. H. Preece wrote that the lighting of the fish wharf might be commenced, and that it would not affect the penalties for non-completion of contract. Four arc lights were ordered to be discontinued on the beach. Four meters, costing £35, and joint and fuse boxes at £50, were ordered to be procured. The customers for the light now numbered 20, taking 1,000 lamps. The receipts from these and from the lighting of Corporation property would be £1,500, and the expenditure would be about

Digitized by Google

£2,650 per annum, a deficiency of £1,150 per annum. A letter was read from Messrs. Grout and Co. asking when an application for a supply of current would be received by the Corporation. The surveyor stated that there were no leads passing Messrs. Grout and Co.'s premises, and that the nearest point was Regent-road. The cost of laying mains to Messrs. Grout and Co.'s premises along by Nelson-road, which was the shorter route, would be £90, but he recommended that the mains should be laid by Langham and Euston roads at a cost of £160. The committee instructed the surveyor to write Messrs. Grout and Co. and ascertain what amount of current they would require. With reference to previous correspondence on the subject of the electric lights on the Parade at Yarmouth, which were reported to interfere with the efficiency of the Caister leading lights, and to the interview with certain members of the Corporation at Yarmouth with a committee of the Trinity Board, on the Trinity House steam-vessel "Argus," on September 13 last, Mr. C. A. Kent, of the Trinity House, wrote as follows to the town clerk: "I am directed to acquaint you that the Elder Brethren are of opinion that the screening to seawards of certain of the lights, as agreed upon at the conference above referred to, will answer the purpose which they had in view. I am at the same time to request that you will convey to your Corporation the thanks of this Board for their courteous compliance with the suggestions of the Visiting Committee." At a meeting on the 6th, the committee instructed the town clerk to write to the contractors, and to take such action as he might consider desirable to compel the completion of the contract at an early date. Mr. Wiltshire: There is a serious delay in the completion of the contract, but no reason is given for it. The Deputy-Mayor: The contractors say they have been unable to get the required material. The Surveyor: Private customers are coming up better than I expected. By additional customers taking the light there will practically be no loss. The report was then adopted.

PROVISIONAL PATENTS, 1894.

NOVEMBER 12.

21782. **Improvements in automatic electrical rheostats.** Thomas Caink, Woodland View, London-Road, Worcester.

21814. **Improvements in electric arc lamps.** Julius Torge, 47, Lincoln's-inn-fields, London.

21821. **Improvements in two-pole single-limb dynamo-electric machines and electrometers having vertical magnets with the poles downwards.** Thomas Parker, Limited, and Thomas Parker, 55, Chancery-lane, London.

21822. **A vessel for the electrolytic separation and alloying of metals in the molten state.** John Clayton Mewburn, 55, Chancery-lane, London. (The firm of Fr. Hornig and Wilhelm Borchers, Germany.)

21827. **A method and apparatus for exciting dynamo-electric generators.** John Imray, 28, Southampton-buildings, Chancery-lane, London. (La Société Anonyme pour la Transmission de la Force par l'Electricité, France.)

21838. **New or improved process for electrolysing chemical combinations and winning the products of decomposition formed by the electrolysis.** Willy Bein, 54, Fleet-street, London. (Complete specification.)

21845. **Improvements in dry batteries.** Richard Myers, 323, High Holborn, London.

NOVEMBER 13.

21855. **Improvements in tools or appliances for use in the trueing up, scouring, or like treatments of dynamo-electric machine cylinders and the like.** Walter Poynter Adams and Rookes Evelyn Bell Crompton, 55, Chancerylane, London.

21879. **Improved methods of effecting the electro-fusion of metals and in apparatus therefor.** Benjamin Howarth Thwaite and Horace Allen, 95, Finsbury-pavement, London.

21893. **Improvements in autographic telegraphs.** John O'Neil, 52, Chancery-lane, London. (Complete specification.)

21929. **Improvements in electric-current regulators.** Herbert Vivian Keeson, 40, Loudon-road, St. John's Wood, London.

21948. **Improvements in holders for incandescent electric lamps.** James Yate Johnson, 47, Lincoln's-inn-fields, London. (Alfred Swan, United States.)

NOVEMBER 14.

21991. **Improvements in or connected with electric tramways and vehicles.** Henry Edmunds, 47, Lincoln's-inn-fields, London.

22029. **Improvements in electrically-propelled fans.** James Henry Pickup and James Henry Hindle, 47, Lincoln's-inn-fields, London.

22030. **Improvements in or connected with electrically-propelled carriages for common roads.** Frank King, 47, Lincoln's-inn-fields, London.

NOVEMBER 15.

22043. **Improvements in means to be employed in connection with the electrical heating of metals for various operations.** William Holland, jun., 6, Livery-street, Birmingham.

22046. **Improvements in arc lamps.** Frank Michael Lewis, 2, East-parade, Leeds.

22070. **An improved process and apparatus for the electrolytic decomposition of metallic salts, and for treating products therefrom.** James Hargreaves and Thomas Bird, Farnworth-in-Widnes, Lancashire.

22119. **An improved method of connecting electrically the rails of tram or rail ways.** Frederic Foley Robinson, 24, Southampton-buildings, Chancery-lane, London.

22134. **Improvements in the electrical propulsion of boats and vessels.** Anthony George New and Arthur James Mayne, 55, Chancery-lane, London.

NOVEMBER 16.

22157. **Improvements in electrical switches.** William McGeoch, jun., 6, Livery-street, Birmingham.

22192. **An electric exploder.** Siemens Bros. and Co., Limited, and Alexander Selgius Schloemer, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

22197. **Improvements in recording telegraphic apparatus.** Antoine Damaskinos, 65, Chancery-lane, London. (Complete specification.)

SPECIFICATIONS PUBLISHED.

1893.

22327. **Electric lamp fittings.** Howes.

24606. **Suspending electric lamps and fittings.** Claremont.

24730. **Indicating time of consumption of gas or electricity.** Curtis.

1894.

2321. **Dynamos.** Yates and Clegg.

7116. **Telegraphic or telephonic call.** Bradbury. (Trinks.)

9763. **Electricity, air, etc., meters.** Cadot and Charron.

9975. **Heating, etc., metals by electricity.** Thompson. (Coffin.)

11439. **Electric indicator or signal.** Wagg.

13499. **Electrolytical decomposition of alkali salts.** Sinding-Larsen.

16243. **Electric propulsion of cars.** Brintnell.

18288. **Secondary batteries.** Riordan.

18339. **Carbons for electric lamps, etc.** Acheson.

NOTES.

Telephony in Spain.—Telephonic communication has been established between Madrid and Barcelona.

Telegraphy in Australia.—The Murchison telegraph line has been constructed to within 40 miles of Mullowa and 12 miles of Cue.

Price Reduction in the States.—The American steel rail makers have reduced their prices for 1895 to 24dol. for girder rails for electric tramways.

Society of Arts.—At the ordinary meeting of this society to be held on Wednesday evening next, December 5, a paper will be read by Mr. Edwin Sachs on "Fire Protection."

Test for Lightning Conductors.—The Government of India has decided to adopt Mr. E. O. Walker's apparatus for testing lightning conductors. A set has been taken also by the Mysore Government.

Telephony in Ceylon.—Major Savage, commanding the Royal Engineers at Trincomalee, has been making some telephonic experiments to make communication complete between Colombo, Kandy, and Trincomalee.

Electric Launch.—Mr. Thomas Orr, jun., Greenock, has received an order to build an electric launch to attain a high rate of speed, and the motor of which, according to a Glasgow paper, is to be on a new principle.

Institution of Junior Engineers.—The next meeting of this society will be held at the Westminster Palace Hotel on the evening of Friday, December 7, when a paper will be read by Mr. William Mallock on "Waterworks and Appliances."

Electrical Instruments.—Mr. H. T. Cheswright, 18, Rue de Mauberge, Paris, has issued a French price-list of the electrical and scientific measuring apparatus and instruments made by Mr. Robert W. Paul, of Hatton-garden, E.C.

Cyanide Process in South Africa.—A communication from Johannesburg, dated 5th inst., referring to the Metropolitan Gold Mining Company, states that their cyanide works—which utilise the Siemens-Halske process—commenced operations the previous week.

Electric Lighting in India.—The *Indian Engineer* learns that Mr. Lester Betts, the agent of the Oriental Telephone and Electric Company, Limited, who has just returned to Calcutta from up country, has secured several good orders for lighting in Agra and district.

Length of Electric Tramways in Europe.—It should have been mentioned in the "Note" given on this subject in our last issue that the figures were in kilometres, and not in miles, as might perhaps have been inferred from the fact of no definite statement having been made.

African Telegraphs.—Reuter's Agency states that Mr. Cecil Rhodes is ordering 650 miles of materials to be sent out for the construction of his Cape-to-Cairo telegraph line. It is estimated that this additional material will suffice to build the line from Blantyre to Ujiji on Lake Tanganyika.

Dividends.—The Allgemeine Elektricitäts-Gesellschaft, of Berlin, have just declared a dividend of 9 per cent. for the year 1893-94, as compared with 8¼ per cent. in the previous year; and the Berliner Elektricitäts Werke have just paid a dividend of 10½ per cent. on the past year's operations.

Economiser Trials.—Trials are shortly to be made at the City of London electric lighting station at Bankside of Messrs. Green's economiser and Mr. Calvert's circular economiser. The City Company have retained the services of Prof. Alexander B. W. Kennedy to make these tests.

Telephony in Belgium.—A Brussels telegram says: "It has been decided to connect this city with The Hague, Rotterdam, Amsterdam, and Flushing by telephone. The convention between Belgium and Holland will be signed at The Hague in the course of a few days. A proposal is also on foot to establish similar communication with Hamburg and Copenhagen."

Surplus and Deficit Theory of Electricity.—With reference to this article, Mr. W. Perren Maycock, M.I.E.E., desires to make the following corrections: November 16—p. 576, second column, line 1, for *Fig. 2* read *Fig. 10*; line 18, for *circuits* read *circuit*; p. 577, first column, line 26, for *article* read *section*; November 23—p. 599, first column, line 7, for *section* (*b*) read *section* (*f*).

Royal Statistical Society.—A special meeting will be held in the lecture theatre of the Museum of Practical Geology, 28, Jermyn-street, S.W., on Tuesday, December 4, 1894, at 4.45 p.m., when a paper on "The Eleventh United States Census" will be read by the Hon. Robert P. Porter, superintendent, and an exhibition of the Hollerith electrical counting-machine will be given by Dr. Herman Hollerith, Washington, D.C., U.S.A.

High Tide in the Thames.—On Tuesday afternoon the tide in the Thames attained an extraordinary height. Some idea of the height of the tide may be gathered from the fact that the water at its flood reached within 1ft. of the platform erected on piles some distance from the southern extremity of Blackfriars Bridge for the purpose of sinking the shaft for the excavation of the Mansion House and Waterloo Railway tunnel.

Patents, Designs, and Trade Marks.—The *Gazette* has published an order in Council applying the Patents, Designs, and Trade Marks (Amendment) Act, 1883, and subsequent amending Acts, to Denmark, including the Faröe Islands. The order is to take effect, so far as regards patents, at the expiration of seven months, and, so far as regards designs and trade marks, at the expiration of four months from the 25th inst.

A New Suggestion.—The Board of Guardians at Brighton find a difficulty in providing work for the inmates which shall be profitable, oakum-picking not fulfilling that purpose. Mr. Merry—evidently a merry man—stated, in the course of a discussion on the subject on Tuesday, that it had been suggested that the inmates "should be employed in generating electricity," and he thought that another guardian, Mr. Dutton Briant, could develop the idea.

London Chamber of Commerce.—A meeting of the Electrical Trade Section will be held at the offices this (Friday) afternoon at 3 p.m. to consider the following agenda: (1) to consider the attitude of the London County Council in regard to placing transformer-chambers in streets; (2) notice of motion by Mr. Sydney Morse as to the methods adopted in the Courts of hearing actions involving electrical questions; and (3) any other matters.

Electric Traction in France.—The success of electric traction on the Lyons-Oullins-St.-Genis line has determined the Lyons Omnibus and Tramway Company to adopt electric traction on their line from the Place Bellecour to St. Fous Vénissieux, on which at present Francq locomotives are employed. The length of this line is 5¼ miles. Mr. Favre intends to construct at Saint-Etienne an electric tramway line on the overhead trolley system.

Society of Engineers.—The next ordinary meeting of this society will be held at the Town Hall, Westminster,

Digitized by Google

on Monday, December 3, when a paper will be read on "The Principles and Practice of Hydro-Extraction," by Mr. H. B. Ransom. The council of the society have unanimously elected Mr. S. Herbert Cox as one of the vice-presidents in the place of Mr. Henry Faija deceased, and Messrs. Henry O'Connor and William Bradford as members of council.

The Electro-Harmonic Society.—There will be a ladies' night this evening (Friday) at the St. James's Hall Restaurant (Banquet-room), Regent-street, W., at eight o'clock, when the artistes will include Miss Mary Harris, Miss Vena Galbraith, and Mr. Reginald Groome. Recitations will be given by Miss Charlotte Boucher, and whistling solos by Mr. C. Capper. The pianist will be Mr. Alfred E. Izard, and musical sketches will be rendered by Mr. Roland Henry.

Utilisation of Niagara Falls.—The following is from the current issue of *Judy*: Stranger (at Niagara): "What a pity it is that up to the present all this water should have gone to waste." Lord Milbank: "Yes, but you know they are going to utilise it for the electric transmission of power." Stranger: "Yes, I know that, but it could have been used more advantageously." Lord Milbank: "Are you an engineer with a new idea?" Stranger: "No; I am a dairyman."

A Curious Argument.—A gentleman writing in a gas organ on the subject of the beauty and utility of the incandescent gas lamp states that in Leith the Police Commissioners, who have adopted some such burners in the streets, are going "to double the number of lamps they are using in street-lighting." This is surely a very strong evidence of the unsatisfactory light given by the street gas lamps. If the writer had hailed from Ireland, it might have been supposed that he had simply made a bull; but he appears to be a Scotchman, so that cannot be the case.

The Madras Electric Tramways.—"With reference to the paragraph which appeared under this heading in our issue of October 20," says the *Indian Engineer*, "we have received a letter from the assistant secretary of the company calling upon us to contradict the concluding sentence, which was as follows: a local paper says, 'There is a general feeling prevalent that the delay manifested in laying down the line is in some degree due to a shortness of funds.' The statement, it appears, was quite untrue and injurious to the company, and we readily express our regret for publishing it."

The Epping Forest Railway.—Notice has been given by the parliamentary agents of the London, Walthamstow, and Epping Forest Railway announcing their intention in the next session to ask authority to abandon the line, to release the deposit, and to dissolve the company. It will be remembered that the promoters last session had a tough controversy with the London County Council on the question of workmen's fares, declaring that it would be impossible to raise the capital under the conditions sought to be imposed upon them, but the Bill was eventually passed on a compromise being arrived at between the promoters and the County Council.

City and South London Railway.—This Company have given notice that they will apply to Parliament to extend the time limited by the City and South London Railway Act, 1890, as extended by the City and South London Railway Act, 1893, for the compulsory purchase of lands for the purposes of the underground railway described in, and authorised by, the first-mentioned Act, and for the completion of the said railway; also to empower the Company to make an additional approach to their King William-street Station, commencing under Arthur-street East, at the eastern end of the station; and to empower the Company to raise additional capital by the creation of new shares or stock.

Trafalgar-square Advertising.—An obviously inspired paragraph has appeared in the *Daily Chronicle* this week to the effect that as a result of the overtures made by the St. Martin's Vestry, her Majesty's Office of Works has, it is stated, decided to take action to secure the suppression of the "nuisance and desecration" (*sic*) caused by the search-light advertisement thrown on Nelson's Column and the neighbouring public buildings. As the Office of Works has at present no power to authorise the abatement of the "nuisance," it is understood that a Bill for that special purpose will be brought into Parliament. Another conference between the solicitors of the St. Martin's Vestry and the Office of Works has been arranged to take place.

Storage Battery Traction.—A German contemporary recently referred to the proposed introduction in Vienna of storage batteries for use on the Hütteldorf-Mariahilf circle. In this connection Dr. J. Stricker, the general representative in Vienna of the Akkumulatoren Fabrik Aktiengesellschaft, writes that the cars will be operated in conjunction with steam cars, which are already in service on that line. The batteries to be used are of the new copper-zinc type of the Waddel Entz Company, which are said to possess all the requirements necessary for successful street traction work. Not being content with the anticipated working results from the company's point of view, an independent committee of 10 technical men has been appointed to follow the experiments and to draw up a report on the subject.

The Pacific Cable.—The *Gazette* of Montreal says: "Referring to Sir John Pender's public statement that the Atlantic cables do not earn adequate returns, and that this ought to be a warning to Governments in the case of the Pacific cable, those who know the facts are in no way surprised that some of the Atlantic companies do not pay good dividends considering the extent to which their stock is watered. Sir John will not be able to get the Commercial Cable Company's statement that Atlantic cables are not a profitable investment, as this company has kept out of the ring with which he is associated. Sir John characterises the Pacific cable as a foolish project, but he has of late repeatedly evinced great anxiety in carrying it out. The warning which he gives may, however, have its use in a way he does not intend in determining the Governments to take such steps as will render it impossible for the Pacific cable to get into the category of water-logged companies, like so many other companies with which Sir John is familiar."

A Curious Scare.—A daily contemporary says: "The success which has already attended the subjugation of Niagara, to obtain power for paper-mill and electric lighting purposes, has brought about the inevitable result. No fewer than six companies are now in existence, formed to utilise the great Falls—that is to say, to divert water from the river's course into turbine pits. The local authorities have become alarmed, and have appealed to the Canadian and United States Governments to exercise some control in order to preserve the rapids. That such an appeal should even have been suggested is almost as remarkable as the original idea of exploiting the great cataract as an engineering enterprise. We may sympathise with those who are organising an opposition to the construction of a railway up Snowdon, but we decline to believe that Niagara is in danger. The preparations on both the American and Canadian shores afford a striking exemplification of the modern utilisation of waste products,

Digitized by Google

for whatever may be said about the grandeur of the Falls, their power has certainly been wasted for centuries."

Bordeaux Exhibition.—A meeting of the committee which has been appointed by the council of the London Chamber of Commerce to further the success of this exhibition, has been held at the offices of that institution, under the presidency of Sir Albert K. Rollit, LL.D., M.P. Those present included Sir Walter Gilbey, Sir Bernhard Samuelson, M.P., Sir Charles M. Kennedy, Messrs. Henry V. Trapp, Paul Aubert, R. W. Fithian, Ernest Clarke, E. Burney Young, and others. It was reported to the committee that the executive of the Bordeaux Exhibition do not propose allocating space for international sections, but that if any desire were expressed for the formation of a British section, proper accommodation might be provided in a separate annexe. Sir Bernhard Samuelson suggested, and the committee agreed, that it would probably be more satisfactory to adhere to the intentions of the Bordeaux executive in classifying the goods of all nations according to groups. The secretary of the Chamber of Commerce is, by direction of the committee, communicating with the Bordeaux executive as to the appointment of a British committee in Bordeaux who will protect the interest of exhibitors. It was stated that all applications for space at this exhibition must be lodged not later than the end of December. Firms who are interested in this exhibition should put themselves in communication at once with the secretary of the London Chamber of Commerce, at Botolph House, Eastcheap, E.C.

Electrocution in America.—A Reuter's telegram states that: "Dr. Gibbons, of Syracuse, who professes to be able to restore animation to a person who has been executed in the usual manner by means of electricity, has arrived in New York for the purpose of explaining to members of the medical profession his apparatus. It is a species of double bellows, about 2ft. in length. By pulling the handle after the indiarubber tube has been inserted into the throat one bellows is filled with fresh air or oxygen, while the other extracts from the lungs whatever air they may contain. By another movement of the handle pure air is projected into the lungs, and vitiated air thrown out of the bellows. Notwithstanding the decision of the Attorney-General for the State of New York, that it would not be legal to experiment upon the body of an 'electrocuted' man, Dr. Gibbons hopes to be afforded an opportunity to carry out such experiments within the next two or three months. He declares that he is satisfied that the alternating current of 1,700 volts now applied does not kill, but only suspends animation, and that it is really the knives used by surgeons at the autopsy that cause death. He says he has experimented largely upon dogs, rabbits, cats, sheep, and cattle, applying from 1,500 to 2,500 volts, and that the animals under his treatment subsequently revived. Dr. Gibbons adds that the apparent death varied from a few moments to several hours, and that he has an assistant who has been similarly revived after receiving 1,500 volts."

Free and Independent Inspiration.—The *Acton and Chiswick Gazette* says that "there is little doubt now that the articles in the *Electrical Engineer* advocating the use of electric traction on the tramways between Shepherd's Bush and Acton were inspired and were intended to deprecate opposition to the Bill which the London United Tramways Company are promoting, and which, if passed, will empower the company to use steam or electric traction on all their lines." Our contemporary is a little "out" in its facts. In the first place, the columns of the *Electrical Engineer* are specially and primarily intended for, and are filled with, matter advocating electrical progress of all kinds, and they are always "inspired" in the best sense. The temptation of a large advertising order from any particular interest is not—and never has been—sufficient (the *Acton Gazette* would soon have found this out if it had made enquiries) to secure favourable mention for a project of any kind in these pages, and we trust our contemporary can say as much; at any rate we note with pleasure its eventual advocacy of the selfsame line we have pleaded for, whatever the inducing cause. In the second place, the Bill now before Parliament is, we are informed on making enquiry, *not* for the purpose of empowering the use of steam power in any shape or form—or electric traction either, for that matter—except on the small piece of new line proposed to be run through Acton High-street. Parliamentary powers authorising the use of electric traction were long ago obtained for all the old West Metropolitan lines, and still hold good. The idea of employing steam traction is absurd, and we even understand that the tramway company is practically pledged to the use of one particular form of electric traction—the overhead trolley—as being on the whole the least objectionable to all concerned.

He Took 4,600 Volts.—Mr. James E. Cutler, of the Stanley Electric Manufacturing Company, U.S.A., writes to the New York *Electrical Review* as follows: "Regarding my recent experience with 4,600 volts, I give you the following facts: The accident was the result of a misunderstanding, and occurred when I attempted to examine a transformer that was being tested with a pressure of 4,600 volts. I leaned over the transformer, and the wires being somewhat in the way I attempted to push them one side, and in so doing got the full shock through my body. For a brief instant I experienced a sensation as if being drawn downward by the arms, then everything became black and remained so for about seven minutes, during which time efforts were being made to restore respiration, the method used being that recommended by D'Arsonval, working the arms and diaphragm to the time of natural breathing. Those standing near said I gave two agonising groans as I fell over, but I have no recollection of having done so. One of the wires had to be pulled out of my hand. Before this could be done I received a further shock through the hips while lying on the floor. For seven minutes there was no sign of a pulse beat, and there was every indication of death. As I slowly regained consciousness, I repeated over and over again incoherent remarks pertaining to the accident. When I first opened my eyes all I could see was a huge black spot, which gradually diminished in size and disappeared. At one time I recognised several people by their hats; the faces I could not see. Half an hour after the accident I could recall every incident happening before and after the few moments of total unconsciousness, that period being a total blank and a painless one as well. I remained quiet the rest of the day—the accident occurred about 10 a.m.—and was around as usual the day after. My nerves were not affected to any appreciable extent, and I shall experience no ill effects other than the scars from the burns, one of which went to the bone.'

Berlin and Vienna Telephone.—A Vienna correspondent of the *Daily Chronicle* says that the telephone between Vienna and Berlin has just been finished, and the first experimental conversation which was carried on between the two cities on Friday last was said to be successful. The line will be opened for public use in a day or two. It is expected that there will be a very large amount of patronage for the line, especially in the way of communications between the two Bourses—so large that it

Digitized by Google

is anticipated that a second and, perhaps, even a third line will very soon be required. During business hours the present line will be exclusively at the disposal of the Bourses in the two cities. The Berlin correspondent of the same paper states that the telephone line, which is about 800 kilometres, or 500 English miles, in length, does not act very satisfactorily. Another Vienna correspondent states that the first conversations were between Austrian and Prussian officials. A slight improvement is, however, necessary before the formal opening of the line. The Vienna correspondent of the *Daily News* stated on Thursday that the previous day at a private trial there were still some disturbing noises. It has been ascertained that the defect is in the line from Berlin to the frontier, whereas the line from Vienna to the frontier work to perfection. He adds: "Our telephone system would appear to be the best that exists. Whenever an Englishman has watched me use the telephone, his expressions of surprise and delight became quite un-English in their enthusiasm. Not only do we set our watches by the telephone, communicate the latest pun, correct mistakes in pronunciation, but set the boys their work, and correct their mathematics on the little desk fixed to the telephone. The ever willing young ladies at the central office often take a lively interest in what is going on, give us pieces of information we might not otherwise obtain, and lovingly ask how we are when we have not called for a couple of days. The telephone in Vienna is perfection, and the connection with Berlin will perhaps have a good effect on the telephone there, which is generally complained of."

Lectures.—Mr. W. H. Preece, C.B., F.R.S., has delivered an address on "The Electric Light" before a large audience at the Young Men's Christian Association, Willoughby-road, N.W. Mr. Hugh M. Matheson, J.P., occupied the chair, and the audience included several members of the Hampstead Vestry and others interested in electric lighting in the parish. At the conclusion of his address Mr. Preece expressed his thanks to Mr. G. Binswanger, general manager of the General Electric Company, of Queen Victoria-street, and Mr. J. T. Niblett, general manager of the Lithanode and General Electric Company, Millbank-street, for the loan of the electrical appliances with which he had illustrated his lecture, and to Mr. I. Probert, superintendent of the electric lighting at the General Post Office, and his assistant, Mr. T. Heather, for their arrangement of the numerous experiments.—A paper has been read before the Glasgow Philosophical Society by Dr. William Smart on "The Municipal Industries of Glasgow," these industries including that of the supply of electric current.—In the course of a paper read by M. Eissler before the Institute of Mining and Metallurgy on "The Practical Operation of the Cyanide Process on the Witwatersrand Goldfields," he stated that it was a strange fact that whilst gold was one of the most difficult of metals to dissolve in acids, it was extremely susceptible to the weakest solutions of cyanide when copper and other metals might remain unaffected in it. In 1887 Dr. Siemens, of Berlin, found that the gold anodes used in electro-plating at his works lost weight when standing in the cyanide liquor without any electric current having passed through the bath. That fact backed up the statements made by chemical authorities that gold was soluble in cyanides, and induced him to try the use of cyanide solutions for the extraction of gold from ores. In order to precipitate the gold from cyanide solutions, only a very weak electric current was required, a density of about 0·06 ampere per square foot being mostly sufficient for the purpose.—Mr. C. J. Jenkin, manager at Nettlefold's works, has delivered a lecture before the Newport (Mon.) Literary Society on "The Electric Current."—A lecture on "Telegraphy" has been given to the students of the evening continuation schools of the Tottenham Board by Mr. A. L. de Lattre, of the engineer-in-chief's office of the Post Office.

Carborundum Electric Light Carbons.—Efforts are constantly being made to improve the quality of carbons, for the purpose of lengthening the life of the filaments, rods, or points, and also to produce a combination of carbon with other substances that would give more light for the electrical energy consumed. Many combinations of materials have been made, both in the mass of the filament, rod, or point, and in the coating of the mass. The main object of inventors has always been to produce a carbon containing a material having an excessively high fusing point and equally difficult of oxidation, and at the same time having a high luminescent value. Mr. E. G. Acheson, the inventor of carborundum, has recently produced a carbon in which he claims to have covered these points. According to the New York *Electrical Engineer* he takes pure carbon and carbide of silicon (carborundum), reduces both to fine powder and mixes them in the proportions of nine parts of the former to one of the latter, together with tar or any other good binding material. The mixture is then baked and moulded into the proper form for use. In order to get the full and complete effect of the illuminating qualities of the carbide of silicon more distinctly separated from that of the carbon, the ordinary cored carbon rod or point is used and the core is filled with the carbide of silicon, either alone or with a binding agent. For the filaments of incandescent lamps, the carbide of silicon, in a very fine powder, is mixed with and suspended in the oil used in the oil bath, for the treatment and building up of the carbons, and in the process of depositing the carbon from the oil bath into the filament, the fine particles of carbide of silicon become fixed to the filament simultaneously with the deposit of carbon. As carborundum is formed at a temperature approximately that of the electric arc, it is necessarily free from all volatile matters and eminently fitted (as the result of having already existed at these high temperatures) for the light-giving body. It has also been demonstrated that it resists oxidation to a greater extent than any other known material, having resisted such chemical action when highly heated and exposed to a stream of oxygen gas. Associated with these two essential qualifications of infusibility and non-oxidisability, is a third equally valuable one, that of luminescence, as it is claimed to produce a greater amount of light for the electrical energy consumed than any illuminating body heretofore used.

Electric Lighting in Germany.—It is proposed to establish a central electric light station at Bunzlau.—The Municipality of Eltville have appointed a committee to enquire into the subject of the electric lighting of the town.—A scheme is projected for the electric lighting of Wirges.—Messrs. Siemens and Halske intend to erect a central station at Warnsdorf.—A large central station is to be erected in Heringsdorf, a sea-bathing resort near Stettin, which will supply current to private consumers, the hotels, and for street-lighting.—The tender of the Allgemeine Elektricitäts-Gesellschaft, of Berlin, has been selected from among a number for the erection of a central station at Kamenz for lighting and power purposes.—The sawmills of Mr. Mathis at Müttersholz have been lighted by electricity for some time, and it is now intended to adopt the electric light in the streets of the town.—A central station has been set in operation at Simbach-on-the-Inn. Various business firms and hotels are taking current, and the streets will also be shortly lighted electrically.—The work in connection with the central station which is

Digitized by Google

being erected by the Offenburg Colliery Company for the electric lighting of Gegenbach, Baden, is making good progress. The conductors are all ready, but the plant at the works has still to be installed. Orders have been received for 800 incandescent lamps, various arc lamps and electric motors, and, in addition, the local authorities have decided to introduce the electric light in the streets.—Work is to be commenced immediately on the central station for Friederichroda.—At Frankfort-on-the-Maine the central station is now giving a day and night supply. There are about 8,000 incandescent lamps connected.—Mr. E. Palmer, gas manufacturer, proposes to erect a central electric light station at Ratzeburg.—A central station has been established by Messrs. Siemens and Halske at Soden, which supplies current to Soden and the neighbouring villages of Kronberg, Königstein, and Mammolshain, and the Friederichshof Palace. There are two Kuhn steam-engines, each of 150 h.p,, and each driving by belting a Siemens alternating-current dynamo. The two machines are run alternately during the evening, while for the day load a third dynamo is employed driven by an 80-h.p. portable engine. The dynamos supply current at 250 volts, and this is raised by five or six transformers to a pressure of 5,000 volts, at which the current is distributed to the various villages, where it is stepped down again to 250 volts in transformer stations. There are 1,000 incandescent lamps installed in the Friederichshof Palace alone. A number of electric motors is connected to the system.

Applications for Provisional Orders.—Notices are now being given in the *London Gazette* of intention to apply for provisional orders for electric lighting in the coming session of Parliament. The following are those which have been announced: by the Corporation of Carlisle, to distribute electricity within the city of Carlisle; by the Walthamstow Local Board, within the district of Walthamstow; by the Swindon New Town Local Board, within the district of the Local Board; by the Pontypool Electric Light and Power Company, Limited, Club chambers, Pontypool, within the district of the Pontypool Local Board; by the Winchester Corporation within the city of Winchester; by the Notting Hill Electric Lighting Company, Limited, to extend their area of supply in the Notting Hill district; by the New Windsor Corporation, within the borough of New Windsor and the district of the Eton Local Board of Health; by the Corporation of Bootle, within the borough of Bootle; by the Victoria Newmarket Gaslight and Coke Company, Limited, to make provision for enabling the company to obtain powers to produce and supply electricity for lighting and other purposes, and to empower them to construct and acquire works, rights, and machinery for the purposes aforesaid, and to apply their capital or funds to all or any of those purposes; by the Liverpool Electric Supply Company, Limited, within the city of Liverpool and in the Local Government district of Toxteth Park; by the Local Board for the urban sanitary district of Radcliffe, within the district of the Local Board; by the Corporation of Worthing, within the district and borough; by the City Commissioners of Sewers to supply proposed baths, wash-houses, and buildings with electricity; by the Southampton Electric Light and Power Company, Limited, within the county borough of Southampton; by the Improvement Commissioners of Llandudno, within the district of the Commissioners; by the County of London and Brush Provincial Electric Lighting Company, Limited, within the district of the Urban Sanitary Authority of Devonport, within the parish of St. Mary, Newington, London, within the district of the St. Olave's Board of Works, London, within the parish of St. Mary, Battersea; by the Local Board for the Urban Sanitary District of St. George, Gloucester, within the district of the Local Board; by the Leigh Urban Sanitary Authority, within their district; by the Charing Cross and Strand Electricity Supply Corporation, Limited, within the district of the Strand District Board of Works; by the Luton Corporation, within the borough of Luton; by the Salisbury Electric Light and Supply Company, Limited, for Salisbury; and by the Windermere Electricity Supply Company, Limited, within portions of the counties of Westmoreland and Lancashire.

"Electric Light and Power."—This was the subject of a lecture delivered on Friday last before the Warrington Literary and Philosophical Society by Mr. F. G. Baily, M.A., lecturer in University College, Liverpool. The lecturer remarked at the outset that the present age had been called generally the age of steam, and if one looked round in Lancashire and all parts of the North of England he would be quite convinced of the truth of the saying. Pretty nearly everything was done by steam, and all the sources of their power were practically summed up in the words "steam-engine." There were a few exceptions perhaps, the gas-engine being the most important, but still they could say that the age was essentially that of the steam-engine. But there were considerable signs that the subsequent ages—the next immediate time—would be to a much larger extent not the age of steam, but the age of coal transferred into electrical power, and that electricity would be the immediate source of all their power in their everyday life. Even at present the various ways in which electricity was applied was one of the most surprising occurrences of the latter end of the century. There was hardly any branch of life to which electricity had not been applied, although the application was only to a limited extent. In most large towns electric lighting was an accomplished fact, and there was to be seen street-lighting, lighting in houses, and all sorts of artificial lighting, down to microscopic slides and illuminating for medical purposes. Heating was thus also done, although to a small extent, with its various applications to cooking and so on. The transmission of power, the carrying of power from one place to another, had received an enormous improvement, notably in the case of the Niagara scheme, and to a limited extent it had been applied in England. There were also wide possibilities in the way of smelting and forging and welding, and nearly all the copper was now purified by electricity. It had a wide application in the medical interest, part of which was of doubtful utility, whilst other applications were based on a thoroughly sound scientific basis. Although he had said that the next age would be one of electricity, they would never get rid in England, at all events, of the coalfields; they could never rely on anything but coal for a source of power, simply because they had no other source. The great advantage of electricity was to simplify the transmission of power very much. It gave them a very much wider range of distance, and a wider range of application at the other end. In conclusion, he said they could expect a large extension of various applications in a few years' time, as soon as people more fully appreciated the benefits to be obtained from electricity, both in electric lighting and in power. Electricity was really one of the most hopeful means of getting rid of the appalling trouble of smoke. It was almost a disgrace to the science of the country that it had not done something material to get rid of it, whereas, as a matter of fact, nothing had been done. One could abolish seven-tenths of the smoke by the use of electricity and good stoking; it would make Lancashire a Garden of Eden if electricity were more generally used.

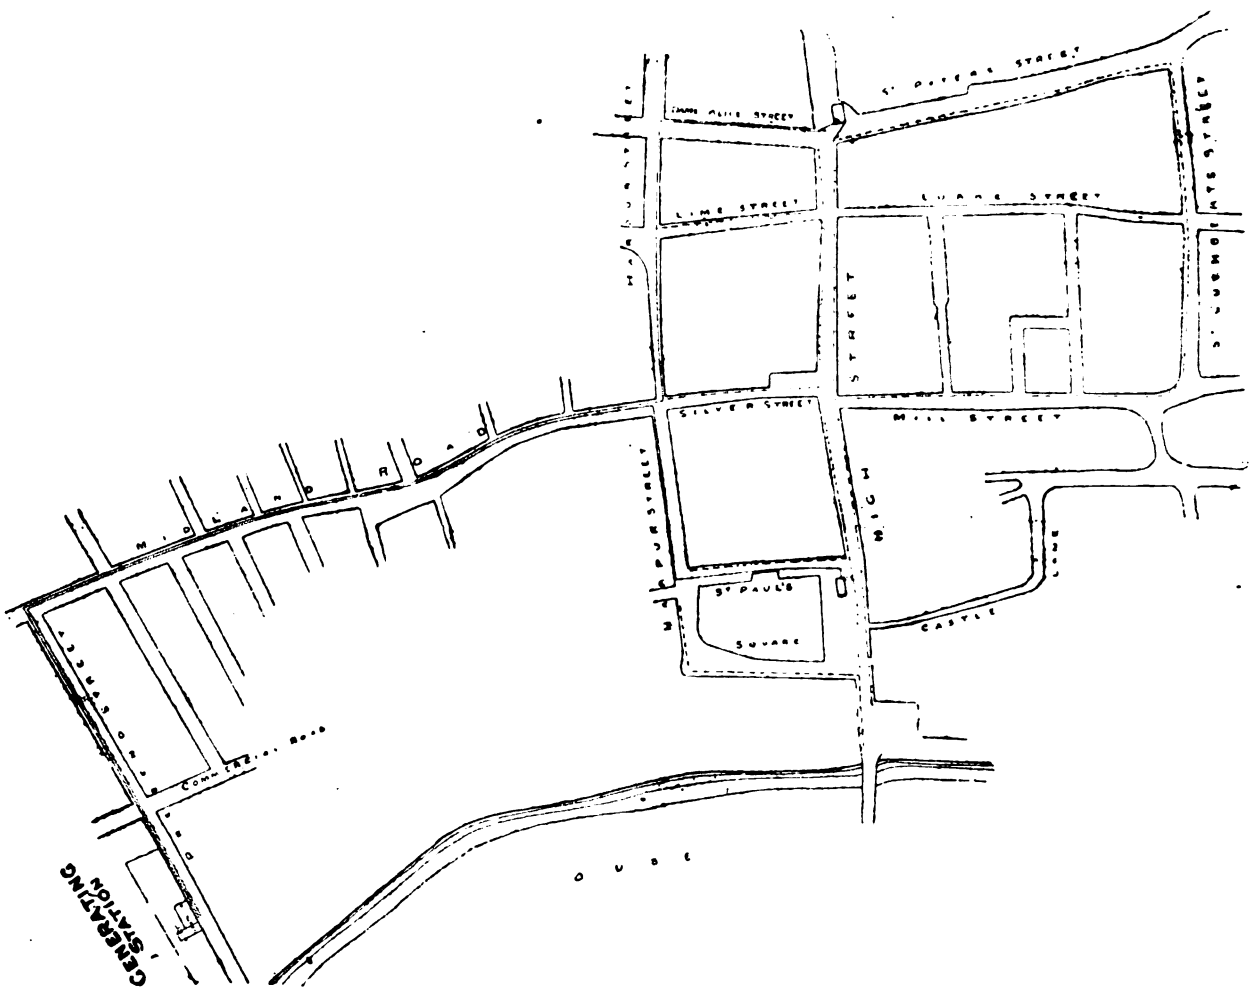
THE ELECTRICITY WORKS AT BEDFORD.

General Remarks.

The prominent characteristics of the town of Bedford are more of an educational than of a manufacturing nature, and hence it has established a wide reputation for the bringing up of the youth of both sexes. Bedford has a long and eventful history, and the district is rich in objects of interest to the antiquarian. Situated on the banks of the Ouse, which passes through the town, it is in direct communication with the Metropolis, the journey to London by rail only occupying about one hour. The town is well paved, and an ornamental embankment, about one mile in length, affords an agreeable promenade on the northern side of the river.



Bedford Electric Light Station.—Map showing in Continuous Lines Route of Feeders and Site of Sub-stations, and in Dotted Lines the Position of the Distributing Mains.

At the commencement of the century the population comprised 4,000 persons, and at present the number of inhabitants reaches approximately 25,000 souls, the area of the borough being some 2,200 acres. The various schools, which it will be unnecessary to particularly specify, are open to boys and girls whose parents, or other legal guardians, are resident in the town. Among the public buildings may be mentioned the Shire Hall, the Corn Exchange, and the Assembly Rooms. The High-street Bridge—one end or the commencement of which is shown on the accompanying plan, was erected over the Ouse in 1813, on the site of the old bridge, which is reported to have supported the gaol where John Bunyan, of "Pilgrim's Progress" fame, was imprisoned.

Preliminary Steps in Electric Lighting.

A few years ago when many local authorities applied to the Board of Trade for provisional orders to supply the electric light, it was considered by the Bedford Corporation that they should also obtain parliamentary powers for this purpose. As a result a provisional order was granted in August, 1890, but the Corporation did not for some years take advantage of the powers thereby conferred upon them. In fact, it seemed at one time as if the provisional order would lapse. Not having taken any definite action in the matter, the Bedford Electric Lighting Company came upon the scene. But to this many of the inhabitants objected. Still the Corporation hesitated, and the company pressed for parliamentary powers. Meetings of the ratepayers were held, and a committee was appointed to prevent, if possible, the provisional order from lapsing into the hands of the company. The matter did not terminate there, and the dispute as to who should supply the electric light in the town was carried to the Board of Trade. It may be as well to recall some of the remarks made by Sir Courtenay Boyle in reply to the deputations to the Board of Trade on the subject in March last. Sir Courtenay Boyle then said:

"The Corporation have had an electric lighting order since August 4, 1890, and not done anything under that order at present, except to give to the difficulties of the situation their careful consideration. The time must come when consideration is not sufficient, and some definite action must be taken, and it seems as if the time has now arrived when, in the interests of a large section of the rate payers of Bedford, some definite steps should be taken. If the Corporation will act upon their order, and will undertake to do something to show that they really intend to carry out their powers, the Board of Trade will be very loth to interfere with those powers. If the Corporation will, as soon as they can, pass the necessary resolution to supply electricity within the compulsory area proposed in the company's order, their assent will not be dispensed with and their order will stand, but if they will not so resolve, their consent will be dispensed with, and an order will be granted to a company. The ratepayers' interests

Digitized by Google

will be safeguarded, because the Corporation's order will not be at once revoked. The compulsory area will be open to reconsideration, so that if the company get the advantages for which they contend they shall be liable to supply at once, or within the compulsory time, a rather more extended area than has been suggested. Something has been said about the position of the company. I have nothing whatever before me to lead me to infer that the company will not be able to satisfy the Board of Trade as to their ability. If the company do not satisfy the Board of Trade within six months as to their ability to carry out their powers in the compulsory area within the limited time, or if they do not conform to the terms as to the compulsory area, their order will be revoked. There is now an opportunity given to the Corporation to decide aye or no whether they will do something or agree together on doing nothing. If they do something their powers will stand, but if they do nothing they will forfeit their powers."

A few days subsequently the Board of Trade intimated to the Bedford Corporation that they would allow the latter six months for the carrying out of the order in the compulsory area proposed by the company. Being thus put on their mettle, the Corporation decided in April last, although not unanimously, to proceed with the work.

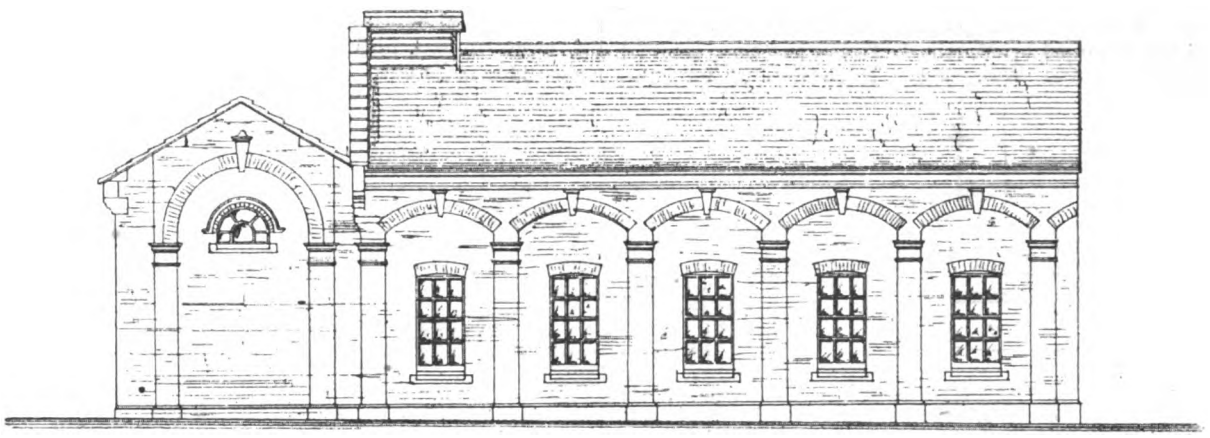
ELECTRIC LIGHTING COMMITTEE.
GEORGE WELLS, J.P., Mayor (chairman).
ALDERMEN:
ASTELL. | YOUNG.
COUNCILLORS:

BLAYDES.	JARVIS.
BURRIDGE.	RICHARDS.
CARTER.	SHELTON.
HARRISON.	SHARPIN.
G. HOWARD.	SPENCER.
J. H. HOWARD.	TAYLOR.

The Electric Lighting Committee (whose names are given above) called in Mr. Francis H. Medhurst, B.Sc., M.I.E.E., of 13, Victoria-street, Westminster, S.W., to advise them on the subject.

The Adopted System.

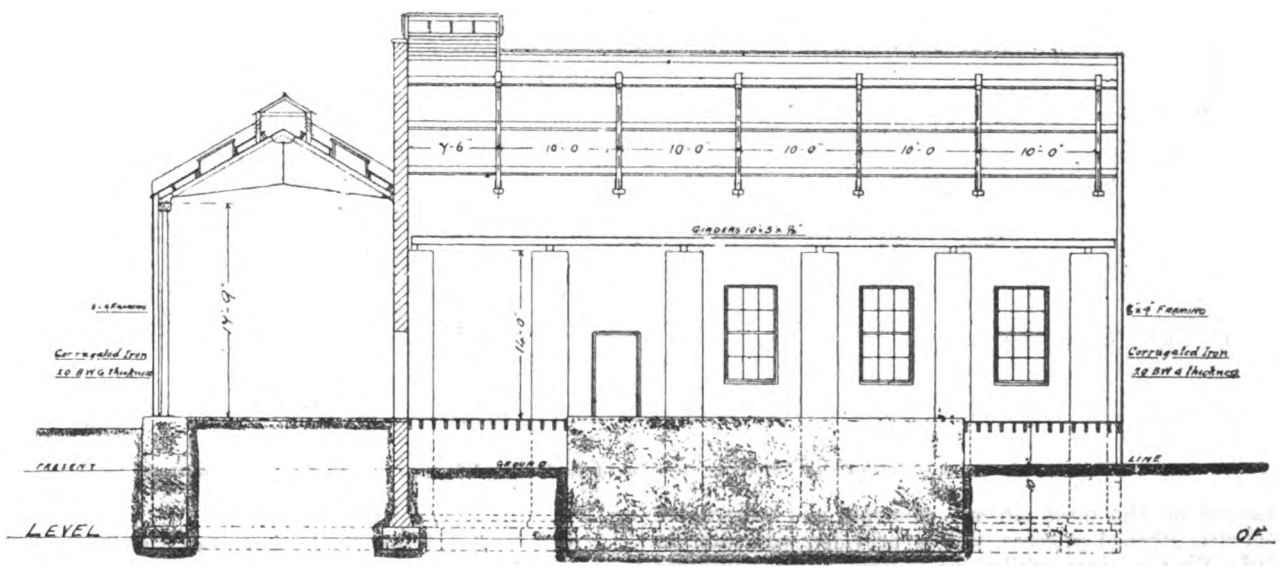
After having taken into consideration the straggling nature of the town and the sites available for the erection of the station, Mr. Medhurst suggested the laying down of a high-pressure alternating-current system of generation, with distribution to consumers from sub-stations at low pressure on the three-wire method. Having adopted this recommendation, the Corporation instructed Mr. Medhurst to prepare plans and specifications for the work. This was done and tenders were invited, the following being accepted:



Bedford Electric Light Station.—Elevation of Buildings from Prebend-street.

Buildings, T. Coleman	£1,565
Plant, Johnson and Phillips	5,200
Mains and transformers, Telegraph Manufacturing Company	2,271
Crane, Grafton and Co.	85
Total	£9,121

As the cost of the buildings may be considered to be low, it is well to explain that this contract did not include the foundations, which were made by the Corporation.



LONGITUDINAL SECTION OF ENGINE HOUSE

Bedford Electric Light Station.—Longitudinal Section of Boiler and Engine House.

The construction and equipment of the station have been rapidly carried out. As shown on the plan, the generating station has been built in Prebend-street, on land belonging to the Corporation, about 1,200 yards from the distributing centre in the town. There is ample space available for extending the buildings from either end, so as to provide for future extensions of the plant. The general arrangement of the station is indicated on the plan of the boiler and engine houses, whilst an external view of the station is given in the front elevation from Prebend-street.

The Boiler-House.

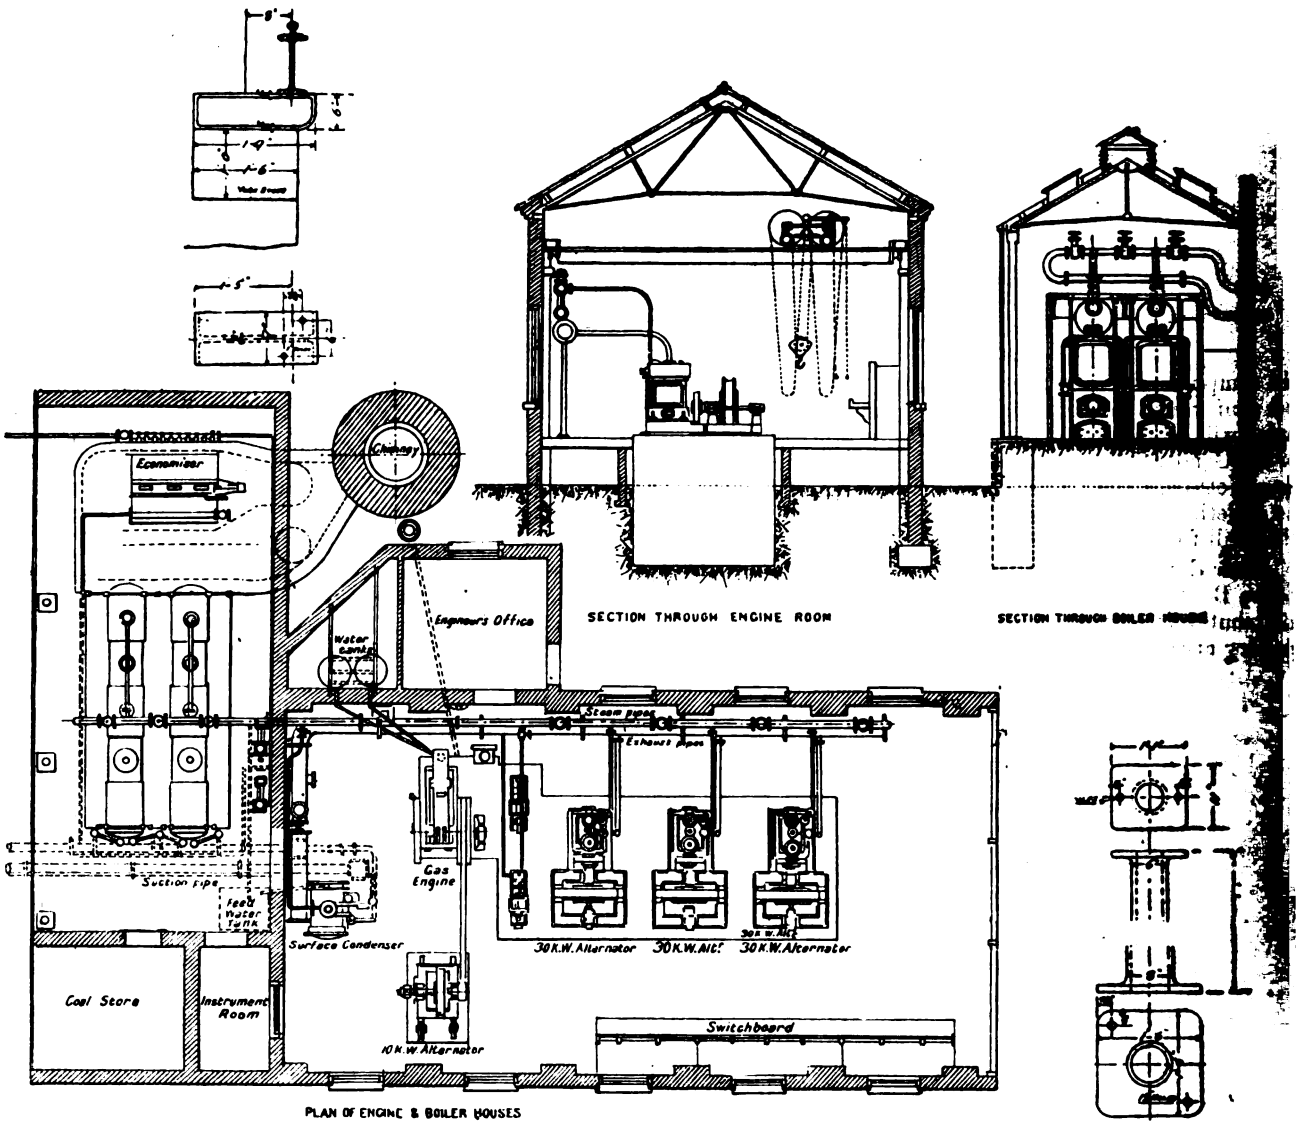
As shown in plan and section, the boiler-house is equipped with two Babcock and Wilcox water-tube boilers, each of

Digitized by Google

which is capable of evaporating 2,500lb. of water per hour, at a pressure of 130lb., with the feed water at 60deg. F. There is nothing new to say of these boilers, which are provided with a double feed service and with Hopkinson's fittings throughout. The feed pumps, of which there are two, are of the Worthington duplex type, each capable of delivering 1,500 gallons of water per hour, and made by the Worthington Pumping Engine Company, of Queen Victoria-street, London, E.C. A Green's economiser is arranged in the main flue, and a galvanised iron feed-water tank is sunk in the floor of the boiler-house, as shown.

The escaping gases from the boilers are utilised to heat the feed water by being passed through the economiser, which was supplied by Messrs. E. Green and Son, Limited, of Manchester and Wakefield. It consists of 96 tubes edge of the Ouse. From this tank a pipe is carried to each pump, either of which can be made to feed direct into the boilers, or force the water round the economiser tubes and thence into the boilers at a much higher temperature.

The steam main, which has been constructed on the ring system, is of steel, 6in. in diameter, with the flanges and branches welded on solid, and is carried through the boiler-house wall into the engine-room. The branch pipes connecting each boiler to the steam main, and the branches from the latter to each engine, are of copper, as are also the bends. The main pipe for the exhaust steam is of cast iron, 14in. in diameter. The exhaust steam from the engines is either taken to the surface condenser, or is allowed to pass into the atmosphere through a vertical pipe 22ft. in height.



Bedford Electric Light Station.—Plan showing General Arrangement of the Plant and Sections through Engine and Boiler Houses.

arranged on the most modern principle, and constructed from strengthened patterns, and is provided with internal lids for the top boxes, whilst the bottom branch pipes are fitted with access caps, thus enabling the tubes and bottom boxes to be readily cleaned internally. The motive power for driving the scraper gearing is afforded by a small high-pressure steam-engine bracketed to the end of the gearing frame, the scrapers thus traversing the pipes continuously from end to end, and preserving a clean heating surface. The sections of pipes were tested to a pressure of 350lb. per square inch, and in the aggregate the economiser contains 960ft. of heating surface.

It may not be uninteresting if we follow the working of the plant in the boiler-house. The feed-water tank is supplied with water both from the town mains and with the hot water coming from the condenser, to which reference will be subsequently made. By means of a valve the circulating water from the condenser can either be passed into the feed tank or into the discharge-pipe laid down to the

The Engines.

It will be seen from the general plan that the engine-room contains three main steam-engines, which are coupled direct to the alternators. These engines, which, together with the exciter engines and condensing plant, were made by Messrs. G. E. Belliss and Co., Limited, of Ledsam-street Works, Birmingham, are double-acting high-speed compound single eccentric engines of the company's E.C./5 standard pattern, running at a speed of 360 revolutions a minute. The high and low pressure cylinders of each engine are 8in. and 14in. in diameter respectively, the length of the piston stroke being 6in. The working parts of the engines, which are enclosed for the purpose of effective lubrication, are readily accessible through a door at the back of the casing.

A noteworthy feature in connection with these engines is the valve arrangement and the method of lubrication. Both the high and low pressure slide valves are placed in the same valve chest and are worked by the same eccentric.

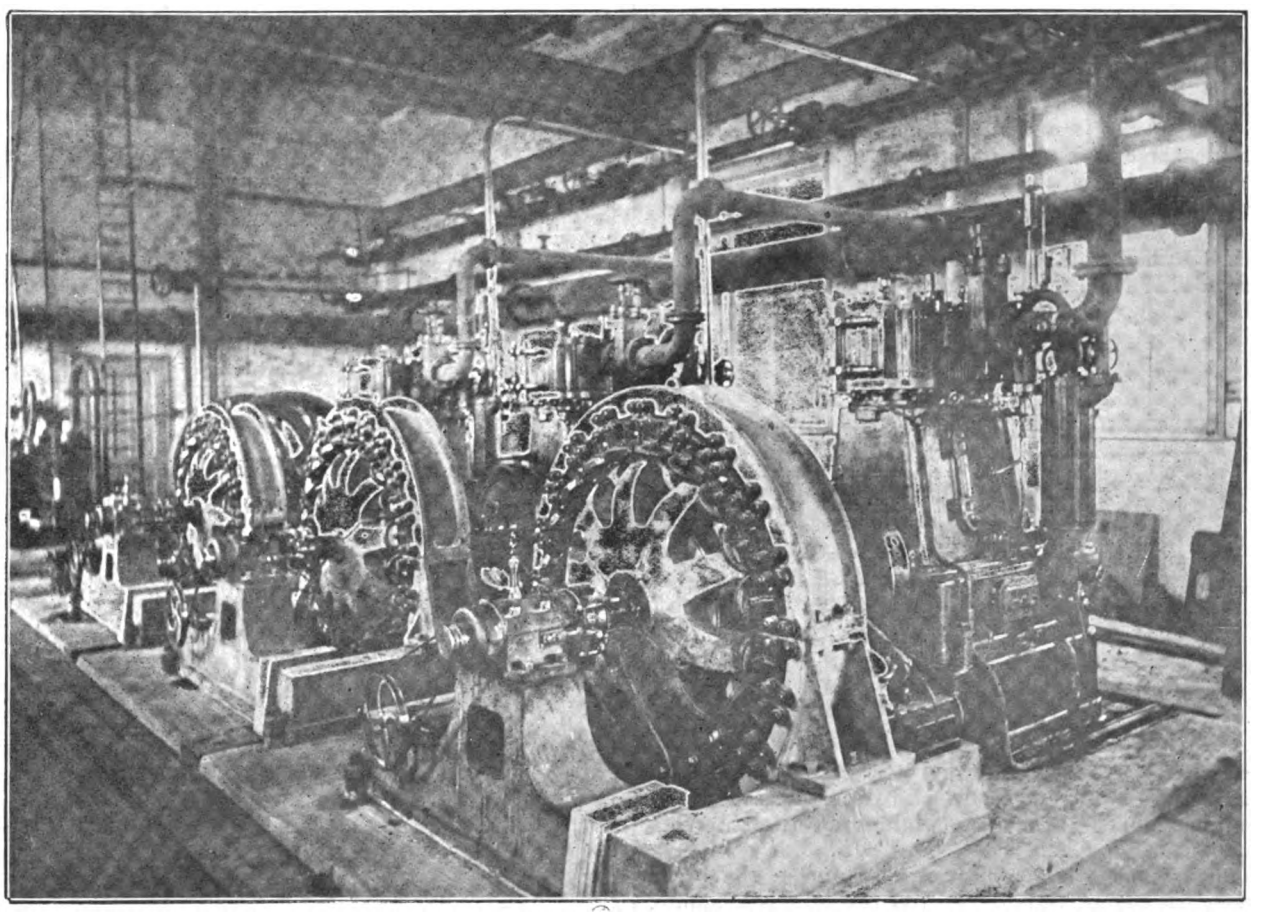
Digitized by Google

The cranks are set opposite to each other, and steam is admitted simultaneously to the top end of one cylinder and to the bottom of the other. As the reciprocating parts are thus balanced, a high speed is rendered possible without setting up undue vibration. This is specially noticeable at Bedford, where more vibration seems to be caused by the gas-engine than by the whole of the steam-engines. As far as the method of lubrication is concerned, the oil is applied to all the engine bearings under pressure from a system of pipes in connection with a tank which is placed at a level of about 20ft. above the engine-house floor. The oil escaping from the bearings drains into the lower part of the crank-chamber and thence into a sump placed below the level of the engine-room floor, whence it is pumped by a small duplex pumping engine back to the tank. Thus the oil is being constantly circulated, and is kept clear of dirt by special filtering arrangements arranged in the high-level tank.

station work. The circulating water is drawn from a well built in the Ouse, which adjoins the generating station, and is twice passed through the condenser tubes. There is a lift of 12ft. from the river level to the condenser base, and the water has to be forced through an additional height of 4ft. in the condenser.

A line of cast-iron suction and discharge pipes has been laid from the condenser to the river—a distance of about 260ft. These pipes have an internal diameter of 8in. The end of the suction pipe which dips into the well is fitted with a perforated suction box. The boiler blow-off pipes and all drains from the steam-traps, etc., in the engine-room are connected to the main discharge-pipe. A cast-iron pipe for the drainage of the economiser is also carried down to the river.

The water drawn from the well by the circulating-pump is passed twice through the tubes—the steam playing outside them. The condensed steam is then either allowed



Bedford Electric Light Station.—Internal View showing Line of Alternators and Engines.

In addition to the three main engines, there are two engines for driving the exciting dynamos. These are also of the enclosed double-acting type, but differ from the others in so far that they have single cylinders 4½in. diameter by 3in. stroke, and run at a speed of 650 revolutions per minute.

The Condensing Plant.

As shown on the general plan, the main exhaust-pipe delivers into a surface condenser, of which drawings are annexed. The condensing plant, which has been supplied by Messrs. Belliss and Co., comprises an independent surface condenser with air and circulating pumps fitted to it. The condenser has tube plates of rolled brass and brass tubes, which are secured to the former by means of screwed glands and tape packings. It has a total cooling surface of 400 square feet, is capable of condensing 4,000lb. of steam per hour, and will maintain a vacuum of 14lb. per square inch in the exhaust-pipes. The air and circulating pumps are both double acting, and are driven direct from the steam-cylinders by a prolongation of the piston rods. The arrangement is simple and compact, and presents many features of advantage for central-

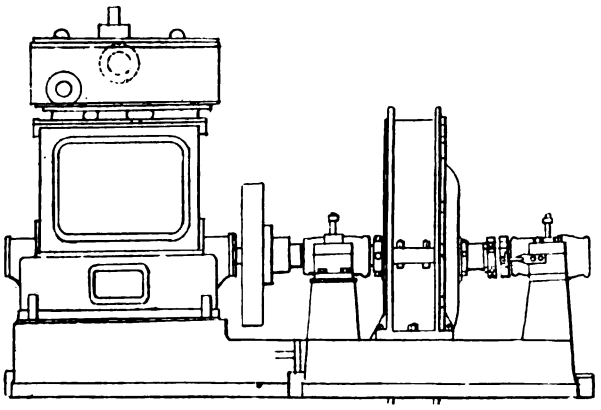
to pass down the discharge-pipe, or, as already mentioned, it is caused to enter, by means of a valve, the hot-well or feed-water tank in the boiler-house. The condensed steam is not used for boiler feed purposes on account of the admixture of oil gathered in the engines.

The Alternators and Exciters.

In coming to consider the alternators, we have to record the interesting fact of the adoption of the new type of machine designed by Mr. Gisbert Kapp, and introduced by Messrs. Johnson and Phillips a few months ago. These alternators have revolving fields and stationary armatures. A plan, elevation, and end view of one of the alternators coupled direct to its corresponding engine are annexed. One of the principal features of this type of machine is the fact that the winding of the field magnets consists of a single coil; the magnets, which are of cast steel, are claw-shaped, and the faces of the pole-pieces are arranged parallel with the shaft. As will be seen from the internal view of the station, the exciting coil is placed on the shaft between the magnets. The coils of the armature are wound over cores formed of charcoal iron stampings, each coil being separately wound, and all the coils are connected in

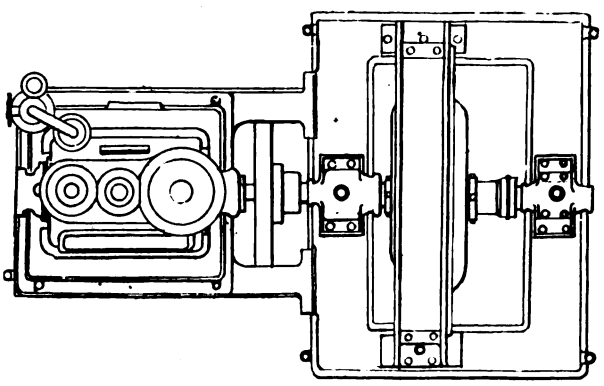
Digitized by Google

series when put into position. It is possible to remove, if necessary, any armature coil that may have become defective, and substitute another in a few minutes. One of the main advantages of this type of alternator is the fact that it can be short-circuited without any fear of being damaged.



Bedford Electric Light Station.—Elevation of Direct-Coupled Belliss Engine and Kapp Alternator.

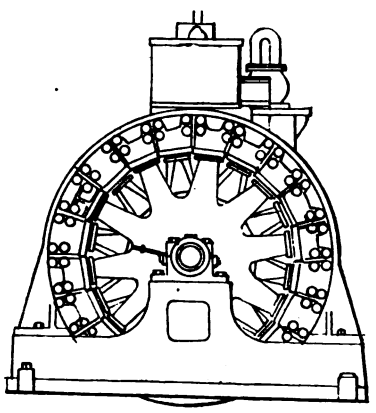
As will be seen from the plan, there are four alternators. Of these, three have each a capacity of 30 kilowatts, the current being 15 amperes at 2,100 volts. These machines are provided with an automatic system of sight-feed lubrication for the bearings. For this purpose a small pump, driven by a belt from an extension of the armature shaft, is provided. The method is entirely automatic, and works well.



Bedford Electric Light Station.—Plan of Belliss Engine and Kapp Alternator.

The exciters for the three large alternators are of Messrs. Johnson and Phillips's type, driven by separate engines, as already mentioned. They are two in number, each giving 66 amperes at 60 volts.

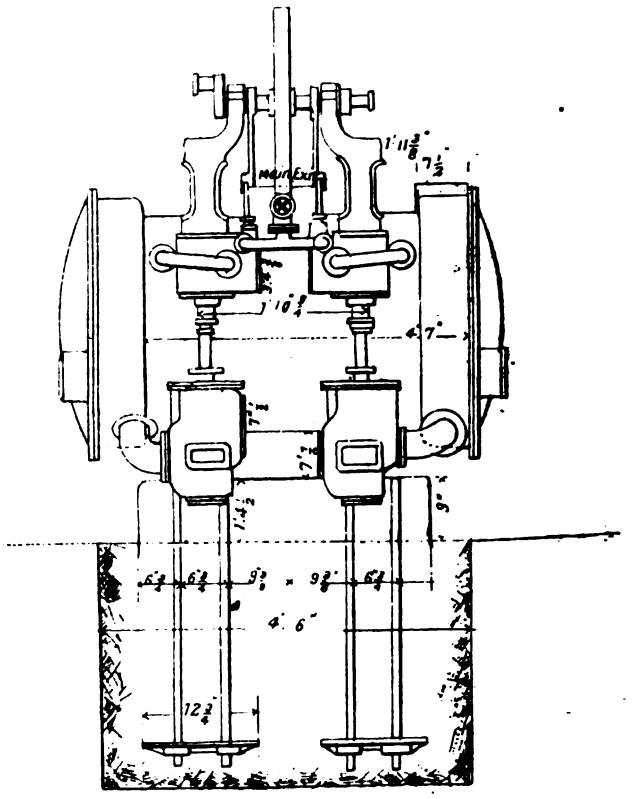
With a view to economical working during the day, a Crossley gas-engine, running at 180 revolutions a minute, has been erected for driving the fourth alternator. The engine is of 20 b.h.p., and is fitted with a double flywheel.



Bedford Electric Light Station.—End Elevation of Kapp Alternator and Belliss Engine.

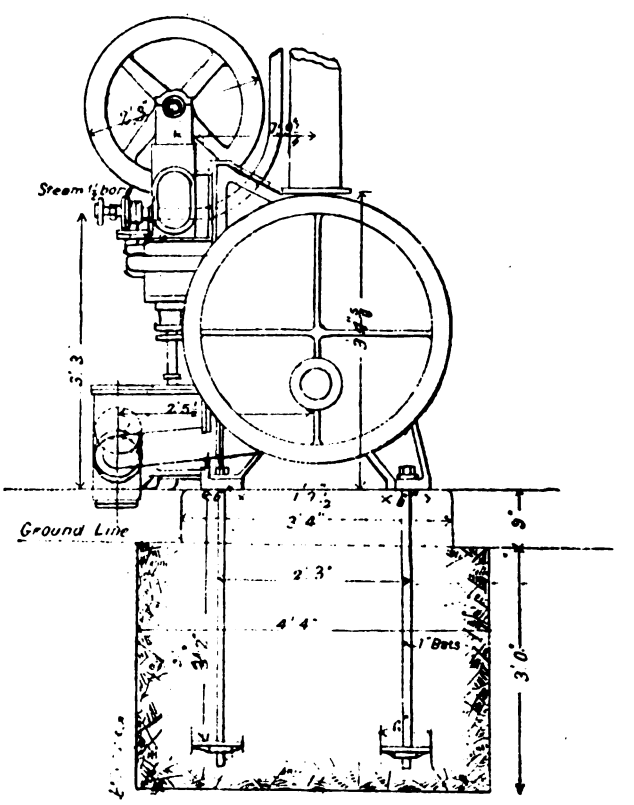
One of the flywheels is grooved to take five cotton ropes, and is provided with an outside bearing and pedestal, so as to prevent any undue strain on the journal. An automatic starting device is employed to set the engine to work. This engine actuates, by means of the five ropes, a 10-kilowatt Kapp alternator of the same type as those previously referred to. The small exciter for this machine is coupled direct to a prolongation of the armature shaft.

The engine-room is equipped with an overhead traveller made by Messrs. Grafton and Co., of Bedford. It has a



Bedford Electric Light Station.—Elevation of Condensing Plant.

capacity of six tons and a span of 29ft. The crab has two main side frames and two cross transomes, and between the cheeks is contained the whole of



Bedford Electric Light Station.—End View of Condensing Plant.

the gearing. This comprises single, double, and treble purchase—the treble purchase being obtained by means of snatch block and return chain. There are four ratchets and an automatic self-sustaining brake, by means of which the load can be held or lowered with ease and safety. The

Digitized by Google

cross traversing motion is also actuated by means of hand hauling chains from below, and it gears direct by means of spur gearing on to one of the axles of the crab.

The Switchboard Arrangements.

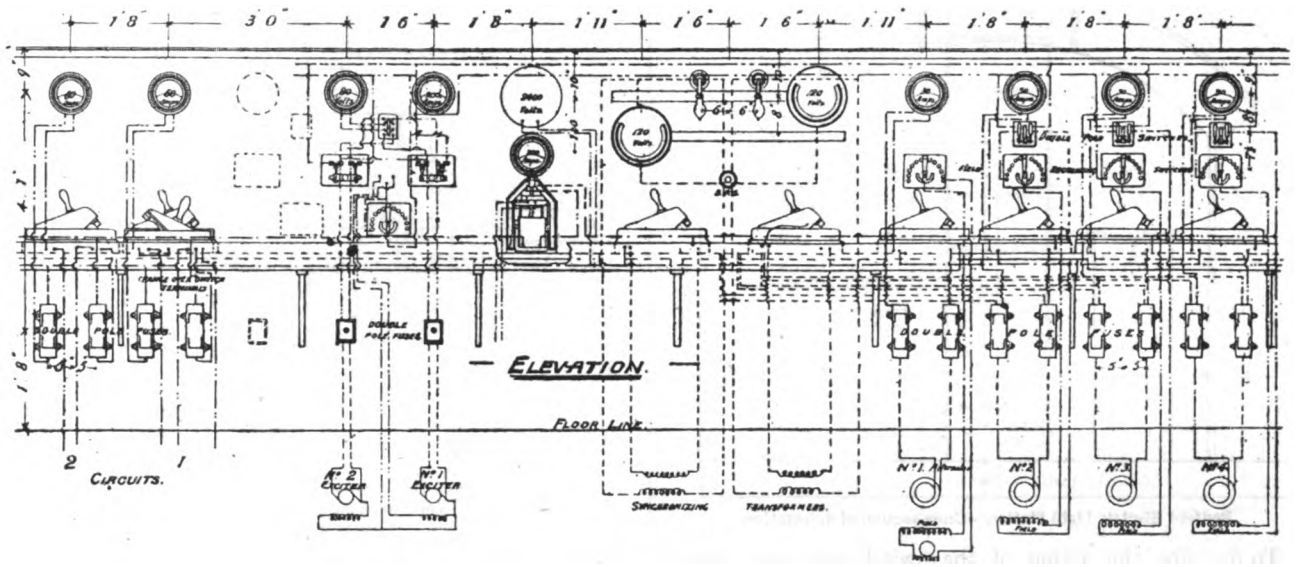
In describing the switchboard, of which a plan and elevation are subjoined, it may be as well to deal with it stage by stage, leaving the gas-engine alternator for the moment out of consideration. Briefly, each alternator is provided on the board with an ammeter, main switch, exciter switch and rheostat, and double-pole fuse; and each exciter with a double-pole switch and a common ammeter and voltmeter and rheostat.

Let us first deal with one alternator, say No. 4. The two leads from this machine are conveyed under the floor of the engine and dynamo room to separate fuses. Both leads are then taken through the main switch; next one is connected to the omnibus bar through the ammeter, whilst the other lead is directly connected to the second omnibus bar. An electrostatic voltmeter and a Mengarini watt-meter are arranged in the circuit. A lead is also taken from each main fuse to the terminals on the synchronising board, where by means of a plug and a switch the alternator is connected to the synchroniser, the primary leads being connected to the primaries of the transformers.

The synchroniser consists of two transformers with an incandescent lamp and a Cardew voltmeter in the secondary circuit of each, and having a double-pole switch to connect the secondaries. The same arrangement is followed in the case of the other two alternators.

The leads from the two exciters are taken to the board through fuses and switches, a third wire being provided for the exciter field. The current then passes through a voltmeter and ammeter on to omnibus bars, from which it is taken to the double-pole field switches and rheostats on the alternator part of the board, where the excitation of the alternator fields is regulated by the latter.

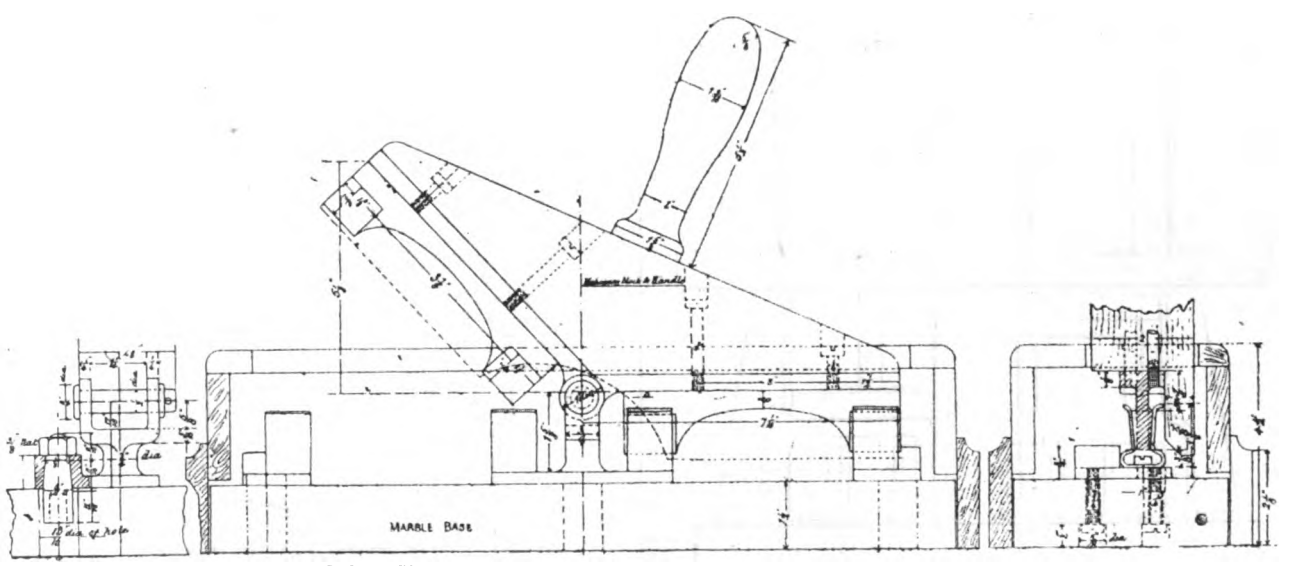
The current from the alternator omnibus bars is led through fuses to two change-over switches, where the feeder circuits, in each of which an ammeter is placed, are arranged, as shown, on the left-hand side of the board.



Bedford Electric Light Station.—Elevation of Switchboard, showing the Connections.

The object of these switches, which have been designed by Mr. Medhurst and Mr. Hope-Johnstone, is to automatically change over at the sub-station from the five-unit transformer to the 30-unit converter, and *vice versâ*. A view of the switch is given.

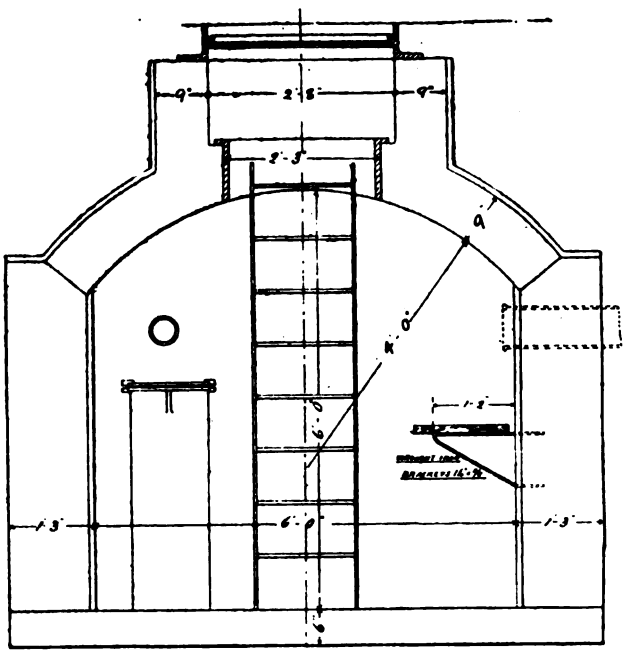
It will be seen from the illustration, which shows the arrangement of the automatic change-over switch at the sub-station, that mercury-cups are fixed on a slate base, and bridging contact pieces are provided on insulating slabs of ebonite. There are three bridging-pieces connecting three pairs of mercury-cups, and three bridging-pieces which connect three other pairs of mercury-cups. Above the mercury-cups two solenoids are fixed, and their iron cores are attached to the ebonite slabs by brass connecting-pieces. The top ends of the covers are each attached to a rocking pulley by means of a short piece of flat link chain. The pulley carries the contact springs of two small switches, one in the circuit of each solenoid winding. Stops are provided to arrest the pulley when the contact-pieces have been lifted out of the mercury-cups by the action of either solenoid. A segment-shaped piece of metal is arranged which moves freely on the spindle of the pulley, and when in the position shown



Bedford Electric Light Station.—Changing-over Switch at Generating Station.

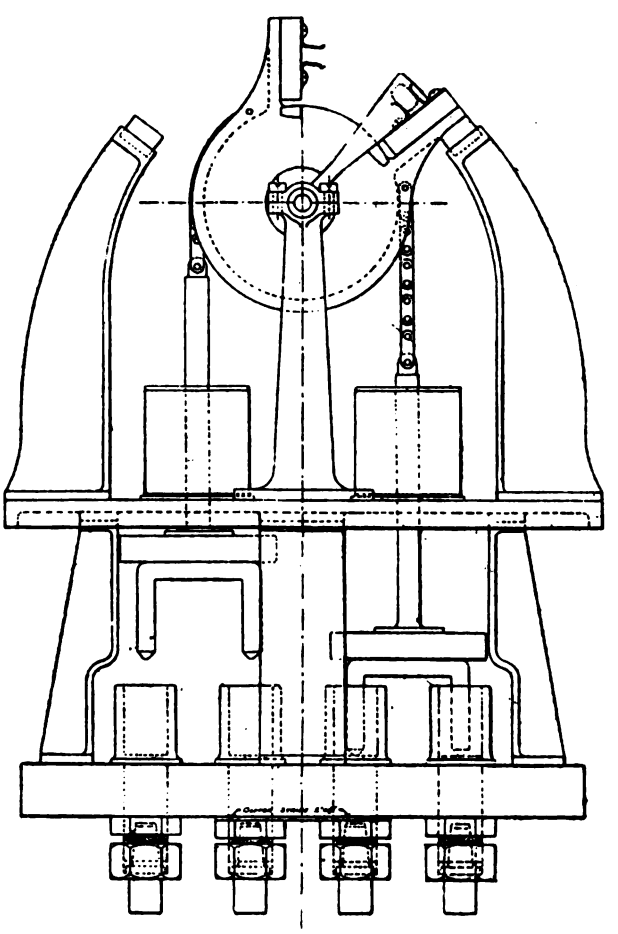
Digitized by Google

makes contact with the springs on the left, and thus completes the circuit of the solenoid to the left. Supports are provided to also form guides to keep the bridging contact-pieces in their proper position.



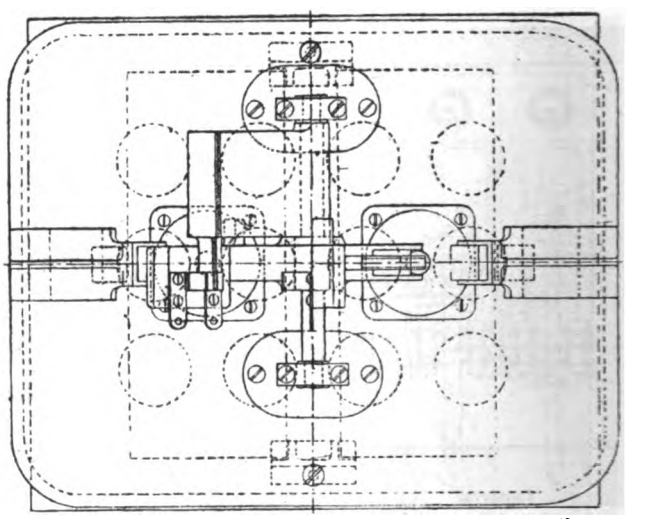
Bedford Electric Light Station.—Cross-section of Sub-station.

To describe the action of the switch, we will assume that the three mercury-cups to the left are connected to the three secondary terminals of the large transformer, and that the three cups to the right are connected to the three secondary terminals of the small transformer. The three



Bedford Electric Light Station.—Elevation of Automatic Change-over Switch at Sub-station.

cups second from the left and the three cups next to them will be connected to the three-wire secondary mains; the left-hand solenoid winding is connected as a shunt across the 100-volt terminals of the large transformer, and the right-hand solenoid winding is connected as a shunt across the 100-volt terminals of the small transformer. Then, in the position in which the switch is shown, the small transformer is connected to the secondary distributing mains, and the moving segment has completed the circuit of the left solenoid. There is, however, no current in this solenoid, because the large transformer is disconnected from the main omnibus bar in the central station. Directly the attendant in the generating station moves the changing switch, thus taking the load off the



Bedford Electric Light Station.—Plan of Connections of Automatic Change-over Switch.

small transformer and putting it on the large transformer, then the left solenoid is excited and attracts its core, thus

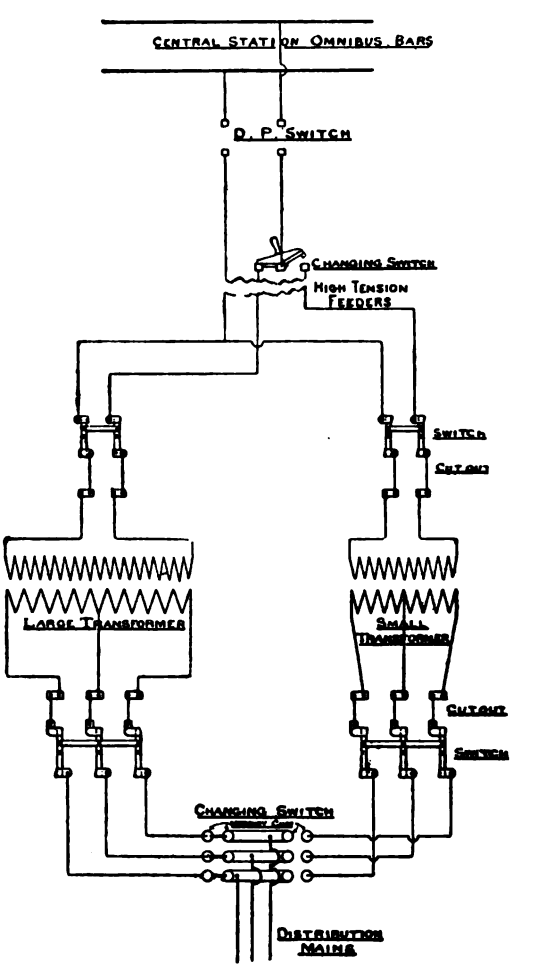


DIAGRAM OF CONNECTIONS TO TRANSFORMERS

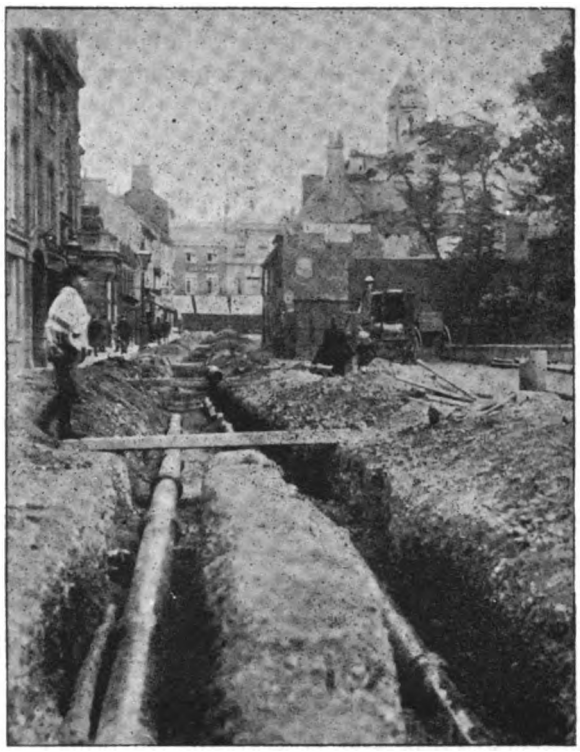
Bedford Electric Light Station.

lowering the bridging-pieces into the two left-hand mercury-cups, and at the same time lifting the bridging-pieces out of those on the right. This breaks the circuit of the small transformer and connects the large transformer to the distributing mains. The pulley will now be arrested by a

Digitized by Google

stop, and the segment will be carried over by its impetus and make contact with the springs on the right, so that the circuit of the left solenoid is broken immediately it has done its work, and the circuit of that on the right is completed ready to operate the switch when it is required. From the above description it is obvious that the solenoids are only momentarily excited, so that the watts wasted in actuating the apparatus are absolutely negligible.

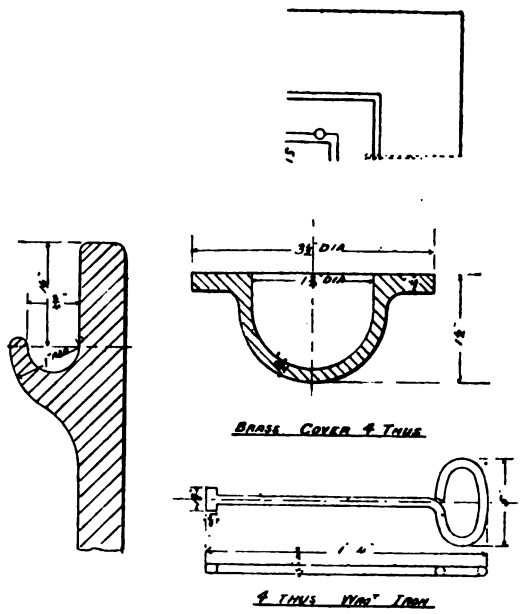


Bedford Electric Light Station.—Laying the Pipes and Cables.

The Distributing System.

As will be observed from the map showing the line of mains, the distribution is effected from two transformer sub-stations, with a three-wire low-pressure network. The sub-stations are built underground, one being at the Bunyan Statue, and the other at St. Paul's-square, as shown. The former contains a 30-unit Parsons transformer, and the latter one of 30 units and one of five units for dealing with light loads. The high-pressure feeders are $^{19}/_{17}$ single cables for the large transformers, and one $^{7}/_{18}$ cable for the five-unit, one of the $^{19}/_{17}$ cables being used as a common return. The large transformers are fed by separate feeders, and are about 1,200 yards distant from the generating station. The transformation is from 2,000 to 210 volts.

The cables are all rubber insulated, and are drawn into lead-jointed cast-iron spigot and socket pipes, the high-pressure mains being drawn into 6in. pipes where they all run together, and into 4in. pipes where they diverge to their respective sub-stations. The three-wire low-pressure system consists of three single cables, at present all $^{19}/_{12}$'s, which are drawn into 6in. pipes in the principal streets, thus permitting additional cables to be drawn in to supplement the two outside conductors, and in the side streets the cables are drawn into 4in. pipes. Cast-iron drawing-in boxes are laid about every 50 yards for the high-pressure pipes, and about every 25 yards for the low-pressure, the latter being also used for service connections. The service pipes are of 2in. wrought iron, screwed into the sides of the boxes.



Bedford Electric Light Station.—Details of Drawing-in Box.

The pipes and boxes are constructed and laid with the object of having them not only watertight, but also air-tight, by means of lead joints in the pipes and rubber joints between the pipes and boxes and between the boxes and lids, the latter being well tightened down with bolts. This arrangement is detailed in the illustrations. It is proposed to instal a suction air-pump at the generating station, and to connect it with the network of pipes. This is a feature much to be commended, and there is no doubt that this arrangement will overcome the difficulty of explosions of gas and air.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIII. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

ELECTRIC COOKING.

What is the value of a pioneer to any industry? We doubt few, if any, of those who come into any industry after the pioneer work is done realise the money value to them of the work of the pioneers. A demand for something is created, and the demand is supplied through a long series of years, not always by those who created the demand, but often by those who had no part in the troublous times, and who reap the reward without deigning to thank those who did the work. The history of electric heating and electric cooking ought to place in the forefront of those who have educated the public, and shown the industry what can be done in this direction, the names of Mr. Dowsing and the firm of Crompton and Co. It is to them, if this branch of the industry succeeds, that success is due. The history of the development in England is, briefly, that the Carpenter system of heating made its appearance here about the time of the Crystal Palace Exhibition. At first it was in the hands of the General Electric Company—at least, it was first exhibited at their stand—then Messrs. Crompton devoted a room to it, and Mr. Dowsing lectured to the visitors. Subsequently Messrs. Crompton took the matter up in a still better business manner, opened a branch establishment under the management of Mr. Dowsing, since when, through evil and through good repute, that gentleman has been persistently and consistently advocating the claims of electricity as a heating servant. Mr. Crompton is down to give a paper at the Society of Arts on the subject. We are inclined to the opinion that an extension of business in the direction of electric heating and cooking utensils means reform in other directions. At first sight it would seem improbable that any connection could exist between such cooking apparatus and architectural designs, but we think a little explanation will show that such connection will, if it does not, exist. Before, however, calling attention to this phase of the subject, we may touch on another. Why should electricity be used for heating purposes as different from cooking purposes? The open grate is a privilege that Englishmen will not readily give up, but it is the open grate, whatever be its advantages, that causes most of the dirt about a room. The dirt and smoke from coal are a nuisance, carpets and furniture cannot easily be kept clean, and because of this there is a daily expenditure of money, an expenditure which must as certainly be reckoned as part of the cost of heating our houses as is the cost of the coal itself. Unfortunately, these indirect expenses are seldom calculated. Few ever think that a new carpet has to be provided a year sooner because of open fires. The smoke troubles we will not discuss. They are only felt to be real sometimes to a Londoner, perhaps, when he revels in a London fog. The indirect cost of burning coal in an open grate is very large, and those who suggest the introduction of any other form of heating rooms should not forget it. It is to this that the architect must pay attention, and, it may be, must in the near future make his designs to include, not heating by

Digitized by Google

means of open grates, but by electrical means. In a vast number of cases heating cannot be treated separately from cooking, hence the combined value for these purposes must be insisted upon. First and foremost, then, comes the question of cleanliness. This has been touched upon above, but cleanliness for cooking purposes is an all-important property, and should be one to commend itself to users of any apparatus. Gas-stoves have been brought to great perfection, and are admirable adjuncts to the kitchen, but gas cannot compare with electricity for cleanliness. Another property of electricity that should appeal to the cook in favour of electricity is the ease and certainty with which the temperature can be regulated. No other form of heating lends itself so well to such regulation. The necessity of a constant temperature is well known to cooks, and hitherto their only method of even approximately getting what they want has been to produce too great heat and then dissipate a portion of it as well as they could. That means a great waste and an increased expenditure. With electricity everything could be regulated to the utmost nicety. Enough has been said, however, to show that this particular phase of the industry will not be allowed to go back for want of convincing arguments. On the contrary, everything seems to favour its more rapid development as central stations become commoner and current is more easily obtained.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTRIC COOKING OF INSTITUTION DINNER.

SIR,—It may interest your readers to know that we supplied seven large electric ovens, four hot-plates, and other electrical apparatus for cooking the above dinner. We had some difficulty at first in convincing the *chef* that cooking could actually be carried out by electricity, and he was so incredulous that he demanded a trial beforehand. Of course, he was soon convinced of the practicability of the matter, and in the end he cooked 16 saddles of mutton, 30 brace of game, and numerous small dishes. Several other dinners served at the same place were also partly cooked by electricity, for the result was so good that the *chef* did all he could that evening by the aid of our apparatus. As a proof that the apparatus gave him perfect satisfaction, the *chef* has written us as follows: "I beg to inform you that as a practical cook of many years' standing, I felt rather doubtful of cooking being done by electricity; but after having used your roasting stoves and other apparatus, I am not only convinced but astonished to see how well joints can be roasted, and in a shorter time than by gas or in front of a range."

We give the above so that members who were unable to see the actual cooking operations carried out may know how the food was prepared, and with what successful results.—Yours, etc., CROMPTON AND CO., LIMITED.

London, S.W., November 27, 1894.

THE DEVIL AND THE DOG.

SIR,—The yellow dog is barking up the wrong tree. It doesn't know the difference between "coal bill" and "coal pile"; and when the wicked printer man goes and confuses them of malice aforethought, the poor bilious-looking jaundiced animal also gets muddled and can't tell "tother from which." Therein he is less clever than the learned pig, who *did* know his letters—but that is another tail, and a curly one. Seriously, however, Mr. Editor, you should feel highly flattered when out of the many pages of letterpress which yourself and contributors send out every week to an admiring crowd of genuine subscribers, an envious and jealous critic is only able to detect a few misprints, dropped letters, and other small villainies—perhaps even a piece of bad grammar, but whisper it low! *If* he were able to find out mistakes of theory and fact, or instances of wilful attempts to mislead the *sometimes* uninformed town councillor, then we should all have to hide our diminished heads, and, like Brer Fox, "lay low and say nuffin"; but things being as they are, don't you know, why all I can say, "Aren't we jolly clever?" Oh! by the way, have you seen that little extract from the just published issue of a monthly technical journal? This is what the editor says: "We have no particular desire to see the technical Press in general undertake the systematic criticism of its competitors. An effort in this direction made by one of the electrical papers, if it serves no other purpose, is useful perhaps as a warning of what might be expected should the average journal assume the office of critic." I couldn't beat that if I tried: so no more from—Yours, etc., P. D.

[The above is from a gentleman who is not unknown as a writer upon electrical subjects, who has made himself an acknowledged position as a specialist on certain phases of electrical work, and hence we can hardly refuse to let him have his say. The so-called criticisms of our contemporary do not concern us. No one takes them as the utterances of independent authority, or as coming from a source which inspires respect. For education they are valueless, for power impotent, and useful only to show the utter inanition of the dregs of technical literature.—ED. *E. E.*]

THE ELECTRICITY WORKS AT BEDFORD.

(Concluded from page 633.)

The low-pressure mains between the two sub-stations are only connected together through suitable fuse-boxes, and as far as possible T-joints have been avoided in the low-pressure mains near the sub-stations by running separate cables from the terminal and fuse boards therein to the various main streets. The high-pressure cables have an insulation resistance of 5,000 megohms and the low-pressure 1,500 megohms per mile. Both high and low tension cables, and also the service wires, are double braided, and finally taped and compounded. All the transformers, switches, and earthing devices and terminal boards in the sub-stations are in separate iron watertight cases. The original contract was for about 2,400 yards of pipes, but this has been increased to 3,800 yards, and all completed within the original contract time.

The whole of the work outside the central station was entrusted to the Telegraph Manufacturing Company, Limited, of Helsby, near Warrington, who have with their own staff, under the superintendence of their engineer, Mr. A. Whalley, installed everything, laid the pipes and boxes, pulled in and jointed cables and services, and also fixed and connected the sub-station apparatus. Everything (excepting the transformers and cast ironwork, which they supplied) was manufactured by the Telegraph Manufacturing Company, including cables, jointing tools, and the necessary testing instruments.

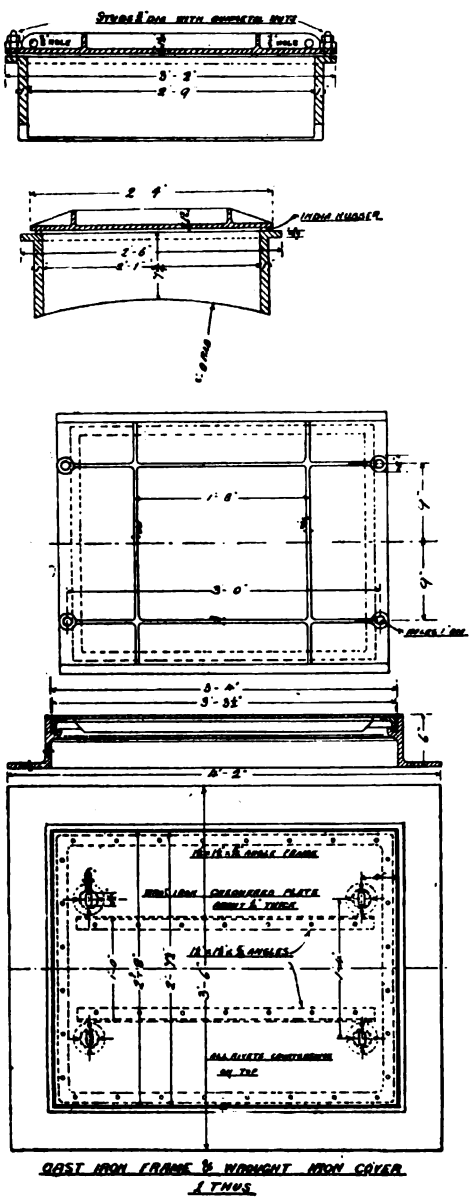
Private and Public Lighting.

It will no doubt have been understood that the generating plant has a capacity of supplying 2,000 10-c.p. lamps simultaneously alight; but this is insufficient to meet the demand. This will be gathered when we mention the interesting fact that even at the present time, when the electricity works are on the point of being set in operation, there are 2,500 10-c.p. lamps already wired, whilst the work of wiring for 500 additional lamps is being proceeded with. This is a very satisfactory commencement, and in order to deal with the increased requirements it has been decided to instal another steam alternator of a capacity of 90 units, and a third 30-unit transformer.

The consumers, who are mostly tradespeople in the centre of the town, will be supplied with electrical energy at 6d. per unit. This compares favourably with the price of gas,

Digitized by Google

which is provided by a company at the rate of 3s. 3d. per thousand, and we should not be surprised to hear of further extensions of the electrical plant at no distant date.



Bedford Electric Light Station.—Details of Frame and Cover of Drawing-in Box.

So far the Corporation, with the exception of deciding upon street-lighting experiments with two incandescent lamps, have done nothing in the matter of public lighting. A few arc lamps judiciously erected in the principal thoroughfares would do much to improve the illumination of the main streets, and no doubt when the electricity works have been in operation for some time the Corporation will be induced to erect arc lamps, or, at any rate, incandescent lamps of high candle-power. As a matter of course, the substitution of electric for gas lamps would transfer a portion of the present outlay on public gas lighting to the revenue of the electricity works, a point which is worth the consideration of the Corporation.

Conclusion.

In bringing this description to a close, we must compliment the Corporation of Bedford upon having established municipal electricity works. Not only so, but our congratulations are due to Mr. Medhurst, the consulting engineer, for the able manner in which the works have been designed and brought to their present successful position. Our thanks are also due to Mr. W. J. Hope-Johnstone, the clerk of works for the plant (who will probably remain at Bedford as the electrical engineer in charge), for his kind assistance in the preparation of this article. Mr. C. Esson, has superintended the installing of the electrical plant on behalf of Messrs. Johnson and Phillips; Mr. H. G. Bone, the erection of the engines and condenser for Messrs. Belliss and Co.; and Mr. J. Hull, the construction of the buildings for Mr. T. Coleman, of Bedford. The undertaking has our best wishes for its success both electrically and commercially.

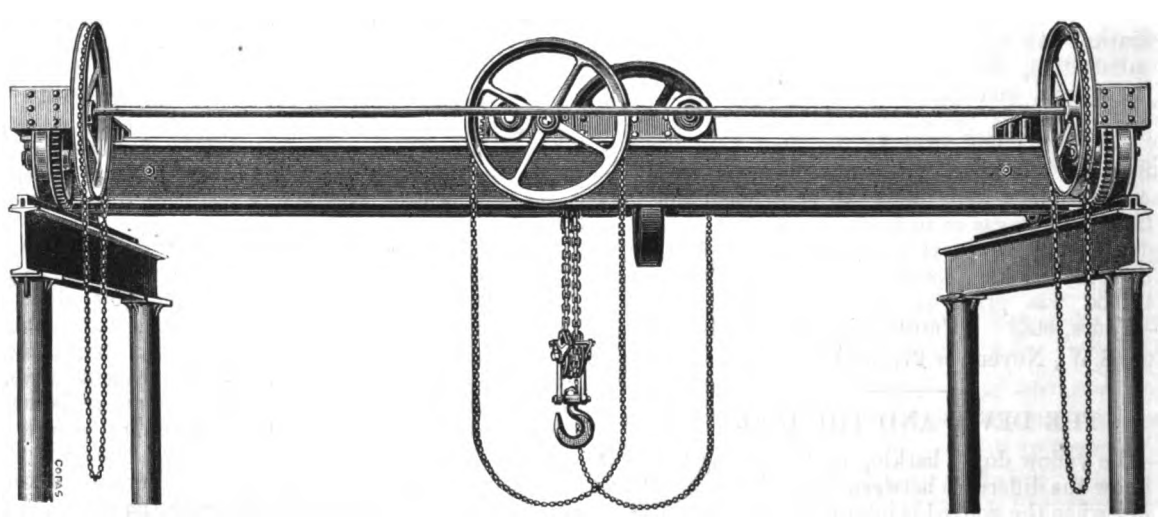
REGULATIONS OF SUPPLY OF CURRENT BY THE BEDFORD CORPORATION.

Conductors.—Each conductor used through an installation shall be of such a sectional area that the current in it shall not exceed 800 amperes per square inch. The section of the conductors shall also be so proportioned that the fall of pressure between the points of connection with the Corporation service wires and the lamps furthest therefrom shall not exceed two volts. Every conductor must be stranded.

Insulation.—The insulating covering of all fixed conductors shall consist of at least one coating of pure india-rubber, one coating of vulcanised indiarubber, braided and compounded to preserve the insulation from mechanical injury; and the above coatings shall be of such thickness that the insulation resistance shall not be less than 600 megohms per mile. This condition need not be adhered to in the case of flexible conductors joined up to the installation through a removable plug fuse, or ceiling rose, but the insulation of these flexible conductors should be of as good quality as possible.

Insulation Tests.—The Corporation reserve to themselves the right of refusing to connect up to their mains installations which have not the following minimum insulation resistances: for 25 lamps, two megohms; for 50 lamps, 1 megohm; for 100 lamps, ·5 megohm; for 150 lamps, ·4 megohm. The insulation will be measured with the lamps removed, but all fuses in place and switches turned on.

Protection for Conductors.—All conductors, where practicable, shall be closed in strong casings of well-seasoned



Bedford Electric Light Station.—Overhead Traveller.

Digitized by Google

wood, the fillet dividing the two conductors being not less than ½in. in width in the smallest-sized casings used, and increased in proportion for larger casings. The lids to the casings shall be screwed down along the outside edges, and not to the central fillet, and in fixing the casings no nails or screws shall be driven through the central fillet. Wherever practicable the casings shall be run upon the surface. Where it is necessary to sink them into plaster walls, the casings must be covered with one coating of oil paint outside and a coating of shellac varnish inside.

Metal Tubes.—The conductors are not to be run in metal tubes. To pass conductors through walls porcelain tubes are recommended. Under no conditions whatever are staples to be used for the fastening down of conductors.

FITTINGS IN CONNECTION WITH INSTALLATIONS.

Switches.—The metal parts of all switches are to be mounted upon non-combustible bases, such as porcelain, the cover being of the same material preferably, or of metal. The switch is to be so designed as to have a "quick-make and quick-break" action, and the metal parts preferably so arranged that screwheads, etc., do not come through to the bottom of the base. Should they do do, the holes must be filled up with plaster of Paris well shellaced, or some equivalent material.

Fuses.—Fuses must be of good design, and similar in general construction to the switches before mentioned. A fuse should be placed on both the positive and negative wire for every branch circuit that is intended to carry more than five lights. All flexible connections must be fitted with a fuse.

Ceiling Roses.—Ceiling roses should be of the same general construction as switches and fuses, and must be fitted with a safety fuse.

Gas Fittings.—Gas fittings are not to be used for the support of incandescent lamps as well as gas.

Arrangement of Circuits.—The "trunk" system of wiring a building is not to be recommended. "The division board" system is always considered preferable, and may, at the Corporation engineer's option, be insisted on.

Apparatus.—Any apparatus not used for ordinary lighting purposes, such as motors, regulating switches, resistance or retarding coils, must be specially approved by the Corporation's engineer.

Connecting.—The Corporation only undertakes to connect up to the house so far as to bring their service wires into a position to be agreed upon. The consumer must run his conductors from the point of termination of the service wires, giving the Corporation facilities for introducing the meter in a position to be approved by the Corporation. The consumer must supply the two main secondary fuses to be inserted as near the Corporation's service mains as practicable, and also a double-pole switch of suitable construction next to the safety junctions.

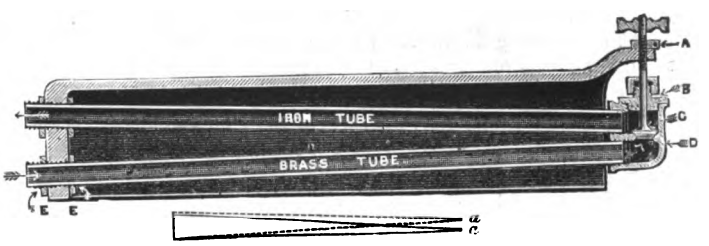
Testing.—The Corporation may refuse to connect up any house before the installation has been tested and inspected by them, and at any date after the house is connected up the Corporation may at once cut off the supply of electricity to it if the installation becomes defective and unsafe. When a consumer makes addition to the number of lights previously installed, the addition must be inspected and passed by the Corporation's engineer before it is connected to the older installation.

General.—The consumers must follow the rules of the fire insurance offices in which they are insured in addition to these rules.

Lamps.—The Corporation are prepared to supply lamps at the rate of 1s. 6d. per lamp (unfrosted) of 8, 10, 16, 25, or 32 candle-power, and at the rate of 2s. 6d. for lamps of 50 c.p., and 5s. for lamps of 100 c.p. This is done for the consumer's own benefit, inasmuch as the market is at present flooded with cheap and inefficient lamps using current very lavishly, and lasting but a very short time. The result is that in order to effect an apparent saving of 6d. per lamp in the first cost, the consumer has his electric light bill increased by from 2s. 6d. to 4s. per annum for every lamp installed. The Corporation will not give a supply of energy to any premises unless they are satisfied that the electric lines, lamps, fittings, and apparatus therein are in good order and condition.

GEIPEL'S STEAM-TRAP.

It has been found that for the high steam pressures now increasingly adopted steam-traps of the old types are not well adapted for this purpose, and the result is that trouble and loss of steam have arisen from their use. This fact was emphasised by Prof. Kennedy, who, in his presidential address to the Institution of Mechanical Engineers, stated that steam-traps required more looking after than all the rest of the machinery combined. This is due to the increased strain on the working parts and joints owing to the high pressure, and to the higher temperature of the steam. Steam-traps may be divided, broadly, into two classes—the one being operated by gravity, the other by expansion and contraction due to changes of temperature. In the former class the working parts are enclosed in a vessel generally made of cast iron, whilst in the latter class the parts need not be so enclosed. This distinction is obviously in favour of the expansion trap, for not only does the case involve the removal of a cover and the remaking of a joint each time the trap is inspected, but the continual oxidation of the levers and spindles, etc., used for opening and closing the valves causes rapid wear, and necessitates continual readjustment. The difficulty with the expansion trap has been due hitherto to the relative smallness of the motion set up in the linear expansion of the metal used, as well as in the positive nature of that motion. This has resulted in the cutting of the valve face and consequent leakage through the valve; for when the trap has been set for use with steam at a particular pressure, and the valve arranged to close with "live" steam at that pressure, it is apparent that should the pressure be increased inadvertently there is increased expansion, to which something must give way.



It is claimed for the steam-trap illustrated, which has been devised by Mr. W. Geipel, that it obviates both these defects. In the first place, the particular form in which the expansion parts are arranged—viz., that of an isosceles triangle—causes a considerable motion to be imparted to the apex for very small changes in the length of these parts; and, in the second place, there is a certain amount of elasticity in the pipes which there is not in the case of the direct thrust generally adopted in these traps. The method adopted by Mr. Geipel in practically applying this trap is shown in the illustration. The lower or brass pipe is connected to the steam-pipe, the upper iron pipe forming the discharge. These two pipes form the two sides of the isosceles triangle above mentioned, the valve seat being at the apex. The valve spindle is fixed to the frame of the trap. When cold the brass pipe is contracted, the apex is drawn down to the position marked *a* so that the valve is fully open, and the water is discharged. As soon as steam enters the brass pipe, the latter expands and raises the apex to the position marked *a*, when the valve is closed. In order that the valve may be set to blow off at any pressure desired, a screw adjustment is provided. In addition to this, when it is desired to blow through, the valve may be opened by hand, and, so that it shall not require resetting after blowing through, there is a lock-nut, A, on the spindle. The valve may be readily examined by unscrewing the top, B. This is a desideratum, as it is a common occurrence for the valves in all steam-traps to become choked with sediment, or to require attention otherwise. The form of the trap is compact, and therefore is very suitable for fixing on the bed-plates of engines. It is also claimed for the trap that it is specially suitable for marine engines, where its use should involve a considerable saving of labour and attention, as well as effecting economy in steam by opening and closing the drain-valves at the proper time. The makers of this steam-trap are the Shillingford Works Company, of 12, London-street, E.C., who state that they have already supplied a number of these traps in different works.

New Publication.—A new fortnightly paper has been issued in Berlin under the title of the *Zeitschrift für Beleuchtungswesen*, which, as the name indicates, deals with questions of illumination. The editor is Dr. H. Lux, whose name is certainly appropriate.

PRACTICAL NOTES ON DYNAMO CALCULATION.*

BY ALFRED E. WIENER.

(Continued from page 393.)

The approximate thicknesses for the various kinds of belts are:

Single belts ..... $h_b = \frac{3}{16}$ in.
Light double belts ..... " $= \frac{9}{32}$ in.
Heavy double belts ..... " $= \frac{11}{32}$ in.
Three-ply belt ..... " $= \frac{7}{16}$ in.

Inserting these figures in (84), the width of the belt is obtained:

$$\text{Single belts} \ldots\ldots b_b = \frac{\cdot 2}{\frac{3}{16}} \times \frac{W}{S_b} = 1\cdot 1 \times \frac{W}{S_b} \quad . \quad (85)$$

$$\text{Light double belts} \ldots b_b = \frac{\cdot 2}{\frac{9}{32}} \times \frac{W}{S_b} = \cdot 7 \times \frac{W}{S_b} \quad . \quad (86)$$

$$\text{Heavy double belts} \ldots b_b = \frac{\cdot 2}{\frac{11}{32}} \times \frac{W}{S_b} = \cdot 6 \times \frac{W}{S_b} \quad . \quad (87)$$

$$\text{Three-ply belts} \ldots\ldots b_b = \frac{\cdot 2}{\frac{7}{16}} \times \frac{W}{S_b} = \cdot 45 \times \frac{W}{S_b} \quad . \quad (88)$$

Single belts are used for all smaller sizes up to 100 kilowatts output, light double belts up to 200 kilowatts, heavy doubles up to 400 kilowatts, and three-ply belts for capacities from 400 kilowatts up.

Based upon the above formulæ, the author has prepared the following Table XLVI., from which the belt dimensions for various outputs and for different belt speeds can readily be taken:

TABLE XLVI.—Sizes of Belts for Dynamos.

Capacity of dynamo in kilowatts.		Thickness of belt, inch.	Width of belt. Belt speed, in feet per minute — 2,000	2,500	3,000	3,500	4,000	4,500	5,000	5,500	6,000
			in.	in.	in.	in.	in.	in.	in.	in.	in.
1	Single belt	3-16	·6	·5	·4	—	—	—	—	—	—
2		3-16	1·1	·9	·7	—	—	—	—	—	—
3		3-16	1·7	1·3	1·1	1·0	·8	—	—	—	—
5		3-16	2·75	2·2	1·8	1·6	1·4	—	—	—	—
7·5		3-16	4·1	3·3	2·75	2·4	2·1	—	—	—	—
10		3-16	5·5	4·4	3·7	3·1	2·75	2·5	2·2	—	—
15		3-16	8·25	6·6	5·5	4·7	4·1	3·7	3·3	—	—
20		3-16	11·0	8·8	7·3	6·3	5·5	4·9	4·4	—	—
25		3-16	—	—	9·2	7·9	6·9	6·1	5·5	—	—
30		3-16	—	—	11·0	9·5	8·25	7·3	6·6	—	—
40		3-16	—	—	14·7	12·6	11·0	9·8	8·8	—	—
50		3-16	—	—	18·3	15·75	13·75	12·25	11·0	10	9·2
60		3-16	—	—	22·0	18·9	16·5	14·7	13·2	12	11·0
75		3-16	—	—	27·5	23·5	20·5	18·5	16·5	15	13·75
100		3-16	—	—	—	—	27·5	24·5	22	20	18·5
150	Double belt.	9-32	—	—	—	—	26·2	23·5	21	19	17·5
200		11-32	—	—	—	—	30·0	26·75	24	21·8	20
250		11-32	—	—	—	—	37·5	33·5	30	27·5	25
300		11-32	—	—	—	—	45·	40	36	32·75	30
400	3-ply	7-16	—	—	—	—	45	40	36	32·75	30
500		7-16	—	—	—	—	56·5	50	45	41	37

The width of the belt being thus determined, the breadth of the pulley rim is found by adding from ½in. to 2in., according to the width of the belt.

PART II.—CALCULATION OF MAGNETIC FLUX.

1.—USEFUL AND TOTAL MAGNETIC FLUX.

31. *Magnetic Field—Lines of Magnetic Force—Magnetic Flux, Field Intensity.*—The surrounding of a magnetic body, as far as the magnetic effects of the latter extend, is called its "magnetic field."

According to the modern theory of magnetism, magnetic attractions and repulsions are assumed to take place along certain lines, called "lines of magnetic force"; the magnetic field of a magnet, therefore, is the region traversed by the magnetic lines of force emanating from its poles.

The lines of magnetic force are assumed to pass out from the north pole and back again into the magnet at its south pole; their direction, therefore, indicates the polarity of the magnetic field.

The total number of lines of magnetic force in any magnetic field is termed its "magnetic flow," or "magnetic flux," and is measured in webers; a field of 1,000,000 webers, or one megaweber, for example, is one containing 1,000,000 lines of force.

The intensity of the magnetism at any point within the region of magnetic influence of a magnet, or the field intensity of a magnet, is expressed by the number of these magnetic lines of force per unit of field area at that point, measured perpendicularly to their direction.

The unit of field intensity is one line of magnetic force per square centimetre of field area, and has received the name of gauss.

A magnet pole of unit strength is that which exerts unit force upon a second unit pole, placed at unit distance from the former. The lines of force of a single pole, concentrated in one point, are straight lines emanating from this point to all directions—*i.e.*, radii of a sphere. The surface of a sphere of one centimetre radius is 4π square centimetres; a pole of unit strength, therefore, has a magnetic flux of 4π absolute or C.G.S. lines of magnetic force, or 4π webers.

The number of C.G.S. lines of force, or the number of webers expressing the strength of a certain magnetic field, must consequently be divided by 4π, or by 12·5664, in order to give that same field strength in absolute units of magnetism—*i.e.*, in unit poles.

A magnetic field of unit intensity also exists at the centre of curvature of an arc of a circle whose radius is one centimetre and whose length is one centimetre, when a current of one absolute electromagnetic unit of intensity, or of 10 practical electromagnetic units—that is, of 10 amperes—flows through this arc. Therefore, the unit of magnetic flux—*i.e.*, one C.G.S. line of force, or one weber—is equal to $\frac{10}{4\pi}$ practical electromagnetic units, or one practical electromagnetic unit $= \frac{4\pi}{10}$ webers.

32. *Useful Flux of Dynamo.*—The total number of lines of force cutting the armature conductors is called the "useful flux" of the dynamo.

According to the definition given in Chapter 1 we have:

$$\text{Volts} = \frac{\text{Number of C.G.S. lines cut per second}}{10^8} \quad . \quad (89)$$

Let now Φ = total number of useful lines, or useful flux, in webers;

K = number of conductors all around pole-facing circumference of armature;

$K = m \times n$, for ring armatures;

$K = 2 \times m \times n$, for drum armatures and for drum-wound ring armatures;

(where m = number of commutator divisions;

n = number of turns per commutator division;

$m \times n$ = total number of convolutions of armature, see Chapter 11).

N = speed in revolutions per minute; and

b = number of bifurcations of current in armature—*i.e.*, number of pairs of armature portions connected in parallel, see Chapters 26 and 27;

then

One conductor in one revolution cuts 2Φ lines of force, for the Φ lines emanating from all the north poles, after passing the armature core, return to the south poles, hence pass twice across the air-gaps, and, in consequence, are cut twice in each revolution by every armature conductor.

The armature makes $\frac{N}{60}$ revolutions in one second, hence

One conductor in one second cuts $2\Phi \times \frac{N}{60}$ lines.

Each one of the $2b$ parallel armature portions contain

* From the *Electrical World* (New York).

Digitized by Google

$\frac{K}{2b}$ conductors connected in series; in each of these $2b$ armature circuits, therefore,

$\frac{K}{2b}$ conductors in one second cut $2\Phi \times \frac{N}{60} \times \frac{K}{2b}$ lines.

But, according to the law of the divided circuit, the E.M.F. generated in one of the parallel branches is the output voltage of the machine; the E.M.F. generated by any armature consequently, by virtue of (89), is

$$E = \frac{\Phi \times K \times N}{b \times 60 \times 10^8} \text{ volts} \quad . \quad . \quad . \quad . \quad (90)$$

and from this we obtain the number of useful lines required to produce an E.M.F. of E volts, thus:

$$\Phi = \frac{6 \times b \times E \times 10^9}{K \times N} \quad . \quad . \quad . \quad . \quad . \quad (91)$$

For dynamos with but one pair of parallel circuits in the armature—*i.e.*, for bipolar machines and for multipolar dynamos with series connections—we have $b = 1$ (see *b*, Chapter 26), and the useful flux for this special case is

$$\Phi = \frac{6 \times E \times 10^9}{K \times N} \quad . \quad . \quad . \quad . \quad . \quad (92)$$

This is the formula usually given in text-books for the useful flux of a dynamo.

(To be continued.)

CITY AND GUILDS OF LONDON INSTITUTE.

LECTURE XII.—GENERAL DESCRIPTIVE KNOWLEDGE OF MAGNETS AND ELECTROMAGNETS. — BEST METHOD OF WINDING ELECTROMAGNET COILS FOR VARIOUS SERVICES.

(Specially contributed.)

Direction of Current and Polarity of Core.—Our definition of a magnet said that, freely suspended, the magnet would take up a position such that its ends would point north and south. I mentioned that the magnetic north pole was not quite coincident with the geographical north pole. The former varies its position between certain limits, while the latter is constant. That end of a magnet which points to the north we, however, call the north-seeking pole of the magnet, or more frequently, because it is shorter, the north pole simply. The opposite end is similarly called the south seeking pole, or, more shortly, the south pole. In many cases, and especially with permanent magnets, the north-seeking pole is marked by means of a notch in the steel or is coloured red, and hence has been called the marked pole. The reason why some people prefer to call the north pointing or seeking pole the marked pole, is because the pole which points towards the north in a magnet is really the south pole of the magnet. However, we need not trouble about this for the present. It is enough if we all agree to call that pole which points towards the north the north pole, and stick to it. Now you may ask how to wind a core, and the proper direction for the current to go through the coils so as to obtain a north pole.

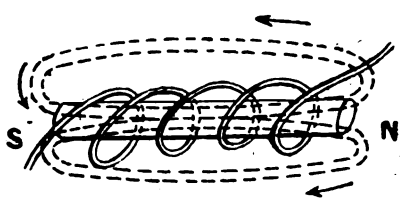

FIG. 1.

Suppose, then, I take a piece of iron, Fig. 1, and hold it so that I face one end. I also take a piece of insulated wire and commence to wind at the farther end. I wind, as you see, towards the right hand. If, now, still facing the end of the core, I send a current through the coil such that it goes from the coil at the top of the core *towards the left hand*—that is, in a direction *opposite* the direction of the hands of a watch—then I shall face a north pole. If, however, I face a pole the current around which is in the same direction as the hands of a watch, then I am facing a south pole.

The lines of force come from the magnet towards you when facing a north pole, and go away from you when facing a south pole. In other words, when the magnetic circuit is partly of iron or other magnetic material and partly of air, the lines of force are supposed to leave the metal at its north pole and enter at its south pole.

It is upon properties belonging to these lines of force that the industrial value of magnetism depends. It is of the utmost importance, then, that the lines of force should be in such positions as to allow the easy utilisation of the properties required. Unfortunately, lines of force are not always easily harnessed.

Density of Lines of Force.—I have explained that if I have a complete ring of soft iron, and generate lines of force by means of a current through the coil on this ring, almost the whole of the lines are within the iron ring. A few escape, but practically all are enclosed. If Fig. 2 represents

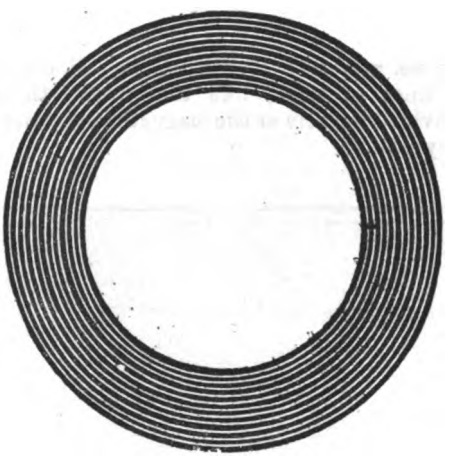

FIG. 2.

such a ring round which all the lines circulate, then the density of the lines is the same throughout the ring—that is, the same number of lines pass through any one section of the ring as pass through another. In this case it is very easy to get an expression for density. Thus let the section of the iron be circular, then the area of the section is

$$A = r^2 \pi.$$

where A = area of section, r = radius, and π = 3·1416, the ratio of the diameter to the circumference of a circle.

Further, let

d = density of lines per square inch;

N = total number of lines;

then $$d = \frac{N}{r^2 \pi};$$

or, density per square inch $= \frac{\text{total number}}{\text{area of section in sq. ins.}}$.

But now suppose the ring is not complete, but that the path of the lines or the magnetic circuit includes an air-gap or air-gaps, as Fig. 3. The lines, instead of going straight across through an air-space whose sectional area is the same as that of the iron, go through an air-space whose sectional area is greater than that of the iron, so that the density of lines per square inch over the greater area is less than in the case before discussed. If the coils acting, or rather the amperes, and the coils acting are as before, the total number of lines will be less if the air-space is an additional resistance to the iron. The number of lines will only be the same when the acting force and the magnetic resistance of the circuit are constant. If the air-gap is very very small compared with the sectional area of iron, the lines will go almost straight across; but if the length of air-gap is long, the lines bulge out largely. Fig. 4 shows

Digitized by Google

the lines as indicated by iron filings across an air-gap. You see a large number go almost straight across, but also a large number bulge out and increase the sectional area of the field very considerably.

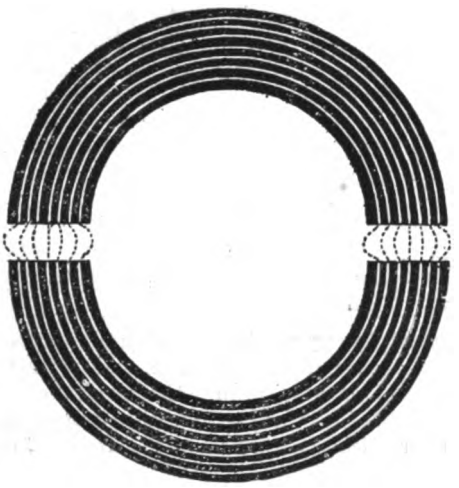

FIG. 3.

I think we may take it without fear of error that the magnetic lines of force, like the current through conductors, divide inversely as the magnetic resistances through which they pass.

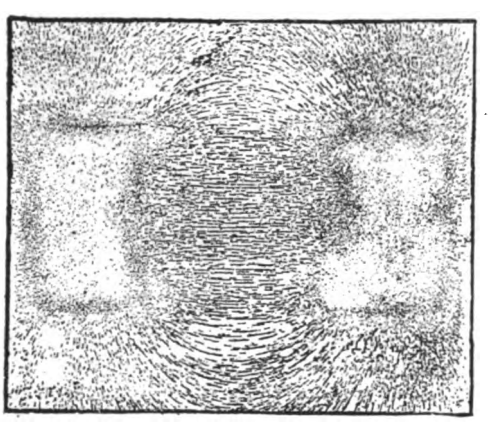

FIG. 4.

Directive Properties of Lines of Force.—Although we have no earthly knowledge as to what causes or constitutes a line of force, it is possible to talk and write about it, and from observed phenomena endow it with properties so as to make a good working hypothesis for the study of magnetism. Let us then assume that the magnetic line of force—that is, the cause—gives us as a result a circuit of matter. Go a little further, and talk about this result as if it was the final point to investigate. A circuit of iron filings is a circuit of tangible matter. But the circuit is there whether the iron filings are or not, and we may therefore assume that in the invisible circuit something tangible takes the place of the filings. This something may be oxygen atoms or molecules, nitrogen atoms or molecules, these being the gases which go principally to make the air-space, or the circuit may consist of air impurities, or adulterations of air, or, further, it may consist of that hypothetical matter called ether. Now, I am fully convinced in my own mind that of whatever any individual line circuit may be composed it is something tangible, and therefore I proceed to endow the line with the property of occupying space. This may seem an unimportant property, but it is not so, as if it exists no two lines can occupy the same space. If, therefore, we have one line or lines existing in a given space, and attempt to put another line or lines in that space, we must, so to speak, push aside the firstcomers, or distort the original contour of the circuit. Now, to push aside or to distort the contour means the expenditure of force. In other words, the existing lines resist being moved or having their shape disturbed. To this resistance we have given the name of *repulsion*. It is owing to this property of resistance or repulsion that when one north pole is brought into the neighbourhood of another, it seems to be pushed away. This push, or repulsion, can be measured. Later on we shall see why a south pole brought near a north pole is not pushed away, but, on the contrary, is pulled towards it. These phenomena give rise to the statement that like poles repel, unlike poles attract.

Continuing the view just expressed, let us imagine two sets of lines of force brought into the same space. But first of all, if the view expressed is correct, we shall see that if any space is *completely filled* with lines of force, it will be absolutely impossible to force any more lines into that space; or as the space gets filled with lines, you will see at once that more and more power is required to force in more lines. Experiment shows this to be correct, for though a small increase of force will at first increase the lines through a piece of iron almost in proportion to the force employed, when the iron begins to get full of lines, or is saturated with them, a very large increase of the producing force fails to send many more lines through. The space, then, into which I tried to bring these two sets of lines is far from being saturated. These sets of lines will only cease to act upon each other when the lines are parallel; hence one magnet, with its bevy of lines, when brought into the field of another magnet will try to take up a position, and will take up that position if free to move, so that its lines are parallel to those of the field into which it is brought.

Now, the earth is supposed to be a huge magnet, and it therefore has its lines of force; hence the reason why any magnet we use, if free to move, takes up a position pointing north and south. It takes up that position because when the position is attained its lines are parallel to those of the earth.

PHYSICAL UNITS.

BY MAGNUS MACLEAN, M.A., F.R.S.E.

(All Rights Reserved.)

(Continued from page 122.)

ELECTROMAGNETIC SYSTEM OF UNITS.

§ 55. In the electromagnetic system all the units are derived from the definition of magnetic pole given in § 48. From the experiments of Oersted and of Ampère we are led to regard a linear conductor carrying a current as producing a magnetic field. If the linear conductor be bent into a circle of unit radius, then unit magnetic pole placed at the centre is acted on by unit force per unit length of the conductor when unit current is flowing in it. The total force acting on the unit pole is therefore 2π units. If Γ be the symbol used to represent current, then

$$[\Gamma] = [F\,L\,m^{-1}];$$

$$= [L\,M\,T^{-2} \times L \times L^{-\frac{3}{2}} M^{-\frac{1}{2}}\,T\,\mu^{-\frac{1}{2}}];$$

$$= [L^{\frac{1}{2}}\,M^{\frac{1}{2}}\,T^{-1}\,\mu^{-\frac{1}{2}}].$$

If we have, as in a practical experiment we would have, a magnet of length l and strength of pole m suspended at the centre of a coil of radius r, large in comparison to l, and if n be the number of turns in the coil, and θ the angle between the plane of the coil and the axis of the magnet, the moment G tending to turn the magnet when a current Γ is in the coil, is

$$G = \Gamma \times m\,l \times 2\pi\,n\,r \times \frac{1}{r^2} \cos\theta;$$

$$\therefore [G] = [\Gamma\,m];$$

$$[\Gamma] = [G\,m^{-1}] = [F\,L\,m^{-1}],$$

which is the same as above.

Let us suppose the coil to be fixed so that its plane is vertical and in the magnetic meridian, that the intensity of

Digitized by Google

the magnetic field at the magnet is H; then when the deflection of the magnet due to the current Γ in the coil is θ, the moment G tending to bring the magnet back to its original position is

$$G = m\,l\,H \sin\theta.$$

Equating these two expressions for G we get

$$\Gamma = \frac{r}{2\pi n} H \tan\theta.$$

$$\therefore [\Gamma] = [L\,H] = [L \times L^{\frac{1}{2}} M^{\frac{1}{2}} T^{-1} \mu^{-\frac{1}{2}}] = [L^{\frac{1}{2}} M^{\frac{1}{2}} T^{-1} \mu^{-\frac{1}{2}}].$$

§ 56. The quantity of electricity Q is equal to the product of the current into the time during which it lasts.

$$[Q] = [\Gamma\,T] = [L^{\frac{1}{2}} M^{\frac{1}{2}} \mu^{-\frac{1}{2}}].$$

§ 57. The work done in urging a quantity Q of electricity through a difference of potential V is, as in § 43, = Q V.

$$\therefore [V] = [W\,Q^{-1}] = [L^2 M T^{-2} \times L^{-\frac{1}{2}} M^{-\frac{1}{2}} \mu^{\frac{1}{2}}] = [L^{\frac{3}{2}} M^{\frac{1}{2}} T^{-2} \mu^{\frac{1}{2}}].$$

§ 58. The capacity of a conductor is, as defined in § 44, the quotient obtained by dividing the quantity of electricity with which it is charged by the potential which this charge produces in it. Hence

$$[C] = [Q\,V^{-1}];$$
$$= [L^{\frac{1}{2}} M^{\frac{1}{2}} \mu^{-\frac{1}{2}} \times L^{-\frac{3}{2}} M^{-\frac{1}{2}} T^2 \mu^{-\frac{1}{2}}];$$
$$= [L^{-1} T^2 \mu^{-1}].$$

§ 59. The dimensions of a resistance are

$$[R] = [V\,\Gamma^{-1}];$$
$$= [L^{\frac{3}{2}} M^{\frac{1}{2}} T^{-2} \mu^{\frac{1}{2}} \times L^{-\frac{1}{2}} M^{-\frac{1}{2}} T \mu^{\frac{1}{2}}];$$
$$= [L\,T^{-1} \mu].$$

§ 60. The coefficient of self-induction of a circuit, in a medium of constant permeability, is the ratio of the counter E.M.F. of the circuit to the rate of variation of the current producing it. In symbols

$$L_1 = e \div \frac{d\Gamma}{dt}$$

where L_1 is the cofficient of self-induction,

$$\therefore [L_1] = [L^{\frac{3}{2}} M^{\frac{1}{2}} T^{-2} \mu^{\frac{1}{2}} \div L^{\frac{1}{2}} M^{\frac{1}{2}} T^{-1} \mu^{-\frac{1}{2}} \times T^{-1}] = [L\,\mu].$$

If M_1 be the coefficient of mutual induction between two circuits, then the counter E.M.F. e^1, in one circuit, due to a current Γ in the other circuit, is $e^1 = M_1 \frac{d\Gamma}{dt}$,

$$\therefore [M_1] = [L\,\mu].$$

§ 61. These electromagnetic quantities may now be put into a tabulated form for convenience of reference:

Name.	Symbol.	Relation to other quantities.	Dimensions in L M T μ.
Current	Γ	Length × magnetic force	$L^{\frac{1}{2}} M^{\frac{1}{2}} T^{-1} \mu^{-\frac{1}{2}}$
Quantity	Q	current × time	$L^{\frac{1}{2}} M^{\frac{1}{2}} \mu^{-\frac{1}{2}}$
Potential	V	work ÷ quantity	$L^{\frac{3}{2}} M^{\frac{1}{2}} T^{-2} \mu^{\frac{1}{2}}$
Electromotive-force	E	work ÷ quantity	$L^{\frac{3}{2}} M^{\frac{1}{2}} T^{-2} \mu^{\frac{1}{2}}$
Capacity	C	quantity ÷ potential	$L^{-1} T^2 \mu^{-1}$
Resistance	R	Electromotive force ÷ current	$L\,T^{-1} \mu$
Self-induction.	L_1	Electromotive force / rate of variation of current	$L\,\mu$
Mutual induction	M_1	Electromotive force / rate of variation of current	$L\,\mu$

§ 62. The dimensions of these electromagnetic quantities have been obtained by starting with the dimensional formula of unit quantity of magnetism, and from it deriving that of unit current. Similarly we might start with the dimensional formula of unit current in electrostatics, and from it derive the dimensional formula of unit quantity of magnetism, and hence of all other magnetic and electromagnetic quantities. For, as in § 55,

$$[m] = [F \cdot L\,\Gamma^{-1}];$$
$$= [L\,M\,T^{-2} \times L \times L^{-\frac{3}{2}} M^{-\frac{1}{2}} T^2 K^{-\frac{1}{2}}];$$
$$= [L^{\frac{1}{2}} M^{\frac{1}{2}} K^{-\frac{1}{2}}].$$

The rest of the quantities need not be worked out in detail. They are all given in the tables below. The reader is also referred to the following papers for further information on this subject: "On the Different Systems of Measures for Electric and Magnetic Quantities," by Prof. R. Clausius (*Phil. Mag.*, June, 1882, p. 381); "On the Dimensions of a Magnetic Pole in the Electrostatic System of Units," by Prof. J. D. Everett (*Phil. Mag.*, May, 1882, p. 376, and June, 1882, p. 431); also articles on the same subject by J. J. Thomson and Prof. J. Larmor in *Phil. Mag.*, June, 1882, pp. 427 and 429; "Remarks on Absolute Systems of Physical Units," by A. F. Sundell (*Phil. Mag.*, August, 1882, p. 81); "On the Dimensions of a Unit of Magnetism in the Electrostatic System of Measures," by R. Clausius (*Phil. Mag.*, August, 1882, p. 124), also J. J. Thomson (*Phil. Mag.*, September, 1882, p. 225), and Oliver J. Lodge, D.Sc. (*Phil. Mag.*, November, 1882, p. 357); "On Systems of Absolute Measures for Electric and Magnetic Quantities," by Prof. H. Helmholtz (*Phil. Mag.*, December, 1882, p. 430).

§ 63. Table of dimensions of electric and magnetic quantities:

Name.	Symbol.	L M T K.	L M T μ.
Quantity of electricity	q Q	$L^{\frac{3}{2}} M^{\frac{1}{2}} T^{-1} K^{\frac{1}{2}}$	$L^{\frac{1}{2}} M^{\frac{1}{2}} \mu^{-\frac{1}{2}}$
Current	γ Γ	$L^{\frac{3}{2}} M^{\frac{1}{2}} T^{-2} K^{\frac{1}{2}}$	$L^{\frac{1}{2}} M^{\frac{1}{2}} T^{-1} \mu^{-\frac{1}{2}}$
Magnetic potential	V	"	"
Surface density	σ	$L^{-\frac{1}{2}} M^{\frac{1}{2}} T^{-1} K^{\frac{1}{2}}$	$L^{-\frac{3}{2}} M^{\frac{1}{2}} \mu^{-\frac{1}{2}}$
Electric displacement	σ	$L^{-\frac{1}{2}} M^{\frac{1}{2}} T^{-1} K^{\frac{1}{2}}$	$L^{-\frac{3}{2}} M^{\frac{1}{2}} \mu^{-\frac{1}{2}}$
Magnetic surface density	σ^1	$L^{-\frac{3}{2}} M^{\frac{1}{2}} K^{-\frac{1}{2}}$	$L^{-\frac{1}{2}} M^{\frac{1}{2}} T^{-1} \mu^{\frac{1}{2}}$
Electric potential	v V	$L^{\frac{1}{2}} M^{\frac{1}{2}} T^{-1} K^{-\frac{1}{2}}$	$L^{\frac{3}{2}} M^{\frac{1}{2}} T^{-2} \mu^{\frac{1}{2}}$
Total electromotive force	e E	$L^{\frac{1}{2}} M^{\frac{1}{2}} T^{-1} K^{-\frac{1}{2}}$	$L^{\frac{3}{2}} M^{\frac{1}{2}} T^{-2} \mu^{\frac{1}{2}}$
Quantity of magnetism.	m	$L^{\frac{1}{2}} M^{\frac{1}{2}} K^{-\frac{1}{2}}$	$L^{\frac{3}{2}} M^{\frac{1}{2}} T^{-1} \mu^{\frac{1}{2}}$
Magnetic pole	m	$L^{\frac{1}{2}} M^{\frac{1}{2}} K^{-\frac{1}{2}}$	$L^{\frac{3}{2}} M^{\frac{1}{2}} T^{-1} \mu^{\frac{1}{2}}$
Intensity of magnetic field.	H	$L^{\frac{1}{2}} M^{\frac{1}{2}} T^{-2} K^{-\frac{1}{2}}$	$L^{-\frac{1}{2}} M^{\frac{1}{2}} T^{-1} \mu^{-\frac{1}{2}}$
Magnetic force	H	$L^{\frac{1}{2}} M^{\frac{1}{2}} T^{-2} K^{-\frac{1}{2}}$	$L^{-\frac{1}{2}} M^{\frac{1}{2}} T^{-1} \mu^{-\frac{1}{2}}$
Magnetic moment	M	$L^{\frac{3}{2}} M^{\frac{1}{2}} K^{-\frac{1}{2}}$	$L^{\frac{5}{2}} M^{\frac{1}{2}} T^{-1} \mu^{\frac{1}{2}}$
Intensity of magnetisation	I	$L^{-\frac{3}{2}} M^{\frac{1}{2}} K^{-\frac{1}{2}}$	$L^{-\frac{1}{2}} M^{\frac{1}{2}} T^{-1} \mu^{\frac{1}{2}}$
Magnetic induction	B	$L^{-\frac{3}{2}} M^{\frac{1}{2}} K^{-\frac{1}{2}}$	$L^{-\frac{1}{2}} M^{\frac{1}{2}} T^{-1} \mu^{\frac{1}{2}}$
Intensity of electric field	f	$L^{-\frac{1}{2}} M^{\frac{1}{2}} T^{-1} K^{-\frac{1}{2}}$	$L^{\frac{1}{2}} M^{\frac{1}{2}} T^{-2} \mu^{\frac{1}{2}}$
Specific inductive capacity	K	K	$L^{-2} T^2 \mu^{-1}$
Capacity	c C	L K	$L^{-1} T^2 \mu^{-1}$
Resistance	r R	$L^{-1} T K^{-1}$	$L\,T^{-1} \mu$
Magnetic permeability	μ	$L^{-2} T^2 K^{-1}$	μ
Magnetic susceptibility	κ	$L^{-2} T^2 K^{-1}$	μ
Self-induction	L_1	$L^{-1} T^2 K^{-1}$	$L\,\mu$
Mutual induction	M_1	$L^{-1} T^2 K^{-1}$	$L\,\mu$

§ 64. It will be noticed from these expressions (1) that mass appears always under a square root and does not appear in any of the expressions involving K and μ to integral powers; (2) that the ratio of the dimensions in terms of K to the dimensions in terms of μ is a power of $L T^{-1} K^{\frac{1}{2}} \mu^{\frac{1}{2}}$. Hence, if we suppose that every electric and magnetic quantity has definite dimensions in terms of length, mass, and time, $K^{\frac{1}{2}} \mu^{\frac{1}{2}}$ must be of the dimensions of a slowness or the inverse of a velocity, and "the two systems become identical as regards dimensions, and differ only by a numerical coefficient just as centimetres and kilometres do." [See "On the Suppressed Dimensions of Physical Quantities," by A. W. Rücker, M.A., F.R.S., *Proceedings* of the Physical Society of London, vol. 10, p. 37; and "On the Dimensions of Electromagnetic Units," by Prof. G. F. Fitzgerald, F.R.S, same volume, p. 95.]

§ 65. By supposing the dimensions of K and μ to be zero, the ordinary electrostatic and electromagnetic systems of units are obtained. The quantities generally used in the two systems are given in the following table:

Name.	Symbol.	Dimensions in electrostatic system.	Symbol.	Dimensions in electromagnetic system.	Ratio.
Quantity...	q	$L^{\frac{3}{2}} M^{\frac{1}{2}} T^{-1}$	Q	$L^{\frac{1}{2}} M^{\frac{1}{2}}$	$\frac{q}{Q} = L T^{-1} = v$
Current...	γ	$L^{\frac{3}{2}} M^{\frac{1}{2}} T^{-2}$	Γ	$L^{\frac{1}{2}} M^{\frac{1}{2}} T^{-1}$	$\frac{\gamma}{\Gamma} = L T^{-1} = v$
Potential..	v	$L^{\frac{1}{2}} M^{\frac{1}{2}} T^{-1}$	V	$L^{\frac{3}{2}} M^{\frac{1}{2}} T^{-2}$	$\frac{v}{V} = L^{-1} T = \frac{1}{v}$
Capacity...	c	L	C	$L^{-1} T^2$	$\frac{c}{C} = L^2 T^{-2} = v^2$
Resistance	r	$L^{-1} T$	R	$L T^{-1}$	$\frac{r}{R} = L^{-2} T^2 = \frac{1}{v^2}$

One electromagnetic unit of quantity $= v$ electrostatic units.

" " " " current $= v$ " "

" " " " potential $= \frac{1}{v}$ " "

" " " " capacity $= v^2$ " "

" " " " resistance $= \frac{1}{v^2}$ " "

where v (determined by experiments to be referred to subsequently) is a velocity of 3^{10} centimetres per second, or 300,000 kilometres per second.

WHAT IS ELECTRICITY?—VII.

BY SYDNEY F. WALKER.

REFLECTION OF ELECTRICAL WAVES.

Readers of my previous articles upon this subject will remember that the view I have ventured to put forward as to the nature of electricity is that it is simply a mode of motion, just as heat, light, and sound are, but at a different rate, and possibly in a different manner, to either of those forces. I have already pointed out the close similarity that exists between the different forces named and electricity, in the fact that conduction takes place in all of them under very much the same laws; that the presence of any one of them, electricity included, in any body increases the apparent size of that body; and that all, though necessarily in different degrees and with different substances, possess the property of altering the chemical constituency of compound bodies.

Seeing that the different forces represent different forms and rates of motion, we should necessarily expect that there would be diversities in the similarities of their resultant action, and, further, we should expect that some properties would be peculiar to one or more rates of motion, to one or more of the forces, but not common to all. The more features of similarity, however, that we find between a force supposed to be outside the group and those known to be inside, the stronger does the argument become that the outsider is really one of the group. If, therefore, we can show that electricity or electric waves are reflected and refracted as heat and light rays are, we shall have a strong argument in favour of my contention that electricity is a mode of motion, like the other physical forces.

As students of electrical literature are aware, the late Prof. Hertz went a very long way towards proving this, and he actually succeeded in obtaining reflection of electromagnetic waves. What Prof. Hertz actually proved was, that if in the path of a series of electromagnetic waves created by an induction coil an object be placed capable of reflecting those waves, just as mirrors reflect waves of light or heat, the actual phenomena of reflection were obtained. My object in drawing attention to this is the hope that some of those who have the time and the appliances at their disposal will carry on Prof. Hertz's experiments to their logical conclusion, and prove or disprove my supposition that an electrically-charged body is sending waves into space, just as a luminous, a heated, or a sounding body does, and that these waves may be caused to reflect and possibly also to refract.

In order to pursue this investigation with advantage it may be well to enquire what we mean by reflection, since it will be evident that a substance that reflects one of the physical forces may not reflect another. To follow the theory I ventured to put forward in one of the earlier articles, the rate of motion already existing in any particular body on which a ray impinges may be such as to combine readily and fully with the motion brought by the ray when the latter is, say, a ray of heat, while it may not be able to combine with a ray of electricity, supposing such to exist. In the case of the reflection of light rays, we see this selective property exercised all around us. Thus, a substance we know as black has the property of absorbing and, on the theory enunciated above, of combining with the whole of the motion brought by the impinging ray. A substance we know as red is only able to absorb a portion of the motion, reflecting the remainder out again, and giving us the phenomena of colour. A substance that is white, as we know, absorbs very little of the motion brought by an impinging ray, reflecting nearly the whole of it; while, again, bright polished substances, such as mercury, silver, and to a lesser degree copper, and other coloured metals have the property, not only of reflecting a mass of light rays, but of reflecting every ray brought to them in the exact inverse order in which they arrive.

To reflect electric rays, then, we require to find a substance that does not readily absorb a charge of electricity, or, in other words, one which, while it is a poor conductor, has also a small electrostatic capacity. An experiment I think that should prove successful might be made with a large hollow metal sphere charged to a very high potential, and the neighbourhood explored with a sheet of ebonite and a light pith ball. If waves of electricity are given out by the highly-charged sphere, just as waves of sound are given out, say, by a tuning-fork, evidence of them would be found and of their reflection. Possibly a careful consideration of some of the phenomena of electrostatic induction may lead to the conclusion that this also is only a form of reflection.

PHYSICAL SOCIETY.

At the ordinary general meeting, held on 23rd inst., Prof. Rücker, F.R.S., president, in the chair, **Mr. Womack** read a paper on "**A Modification of the Ballistic Galvanometer Method of Determining the Electromagnetic Capacity of a Condenser.**" The condenser is placed in parallel with one arm, S, of a Wheatstone's bridge arrangement of non-inductive resistances. A balance for steady currents having been obtained, the condenser is placed in circuit, and the throw on depressing the battery key determined. The condenser is then thrown out of circuit, and the proportionality of the arms of the bridge disturbed by changing the value of S to $S + dS$. The steady deflection due to this change

Digitized by Google

is then read. From these two readings and the known value of S and dS the capacity is immediately determined. In practice, readings of deflection may be taken with equal positive and negative values of dS. To avoid changes of E.M.F. of the battery, the author finds it best to use a reversing key in the battery circuit, and to observe the throw on reversing the current instead of on simply breaking it. One advantage of the method is that there is no need to know the galvanometer or battery resistance, and the author points out that it may be of service in the simultaneous determination of the resistance and of the joint capacity and inductance of a submarine cable, or of a telephone or telegraph line.

Prof. Perry asked what were the advantages of the method as compared with the Rayleigh-Sumpner method.

Mr. Blakesley thought that the correction for damping in the ballistic part of the experiment might be avoided if in the second part the disturbance of balance due to the increment, dS were measured by half the first throw of the needle on making the galvanometer circuit, instead of by the steady deflection. He doubted whether reversing the current in the battery circuit would have just twice the effect of simply breaking the circuit.

In reply, **Mr. Womack** said he had not tried the method of reading suggested Mr. Blakesley, but with regard to the reversing of the battery circuit, that was found to give in practice as nearly as possible twice the deflection which resulted from simply breaking.

A paper by **Prof. S. P. Thompson** and **Mr. Miles Walker** on "**Mirrors of Magnetism**," was read by Prof. Thompson. It was pointed out that, corresponding to the theory of electric images produced by insulated conductors, there is a theory of magnetic images produced by bodies of infinite magnetic permeability. A magnet pole in the latter theory is the analogue of an electric charge in the former, and a body of infinite magnetic permeability is the analogue of an insulated conductor (which is electrostatically indistinguishable from a body of infinite dielectric capacity). Experiments were made to determine how far the magnetic images due to thick sheets of iron recorded with those deduced by theory for the case of infinite permeability. The image of a north pole in an infinite plane sheet should consist of a south pole of the same strength at a point coinciding with the optical image of the north pole, together with an equal north pole distributed uniformly over the surface of the infinite sheet, as a free electrical charge would be, and so exerting no finite action. Working at distances of a few inches in front of the surface, a sheet of iron a few feet in length and breadth and a couple of inches thick was found to realise the theoretical conditions with very tolerable exactness. In a coil of wire placed on one side of the sheet a current was started or stopped, and the electromotive impulse produced in a subsidiary exploring coil was detected by means of a ballistic galvanometer. That the effect of the actual mirror was equivalent to that of the theoretical image was verified by substituting for the iron a coil equal and similar to the first, and coinciding with its optical image. Sending the same primary current as before round the two coils (with due regard to its direction in the second coil), hardly any appreciable difference in the secondary impulse was observed. This was found to hold good whether the original primary coil had its axis perpendicular or oblique to the plane of the magnetic mirror. Some observations on spherical sheets were also recorded, but in this case the conclusions were less simple.

The paper was followed by a discussion, in which **Mr. Boys**, **Prof. Perry**, **Prof. Ayrton**, **Dr. Burton**, **Mr. W. Bailey**, and **Prof. Carey Foster** took part.

Prof. Ayrton exhibited a "**Student's Apparatus for Verifying Ohm's Law**," designed by himself and Mr. Mather. The current flowing through a circuit is to be measured (not necessarily in terms of any defined unit) by means of a galvanometer, while the potential difference between two fixed points is measured by means of an idiostatic electrometer. Within small limits of experimental error the current and potential difference are found to vary in the same proportion, but the electrometer and its manner of use constituted the chief interest of the paper. The fixed and moving parts (inductors and needle) are alike cylindrical in form (the term being understood in its most unrestricted sense) and the generating lines are vertical. There is a vertical axis of symmetry, such that the disposition of these cylindrical parts would remain unchanged if the instrument were rotated through 180deg. about the axis. The needle is hung by a very thin phosphor-bronze strip, and to obtain a reading when it differs in potential from the inductors by an amount which we have to measure, it is brought back to its ordinary zero position by turning a torsion-head to which the upper end of the suspending strip is fixed. The potential difference is then proportional to the square root of the angle through which the torsion-head has been turned, but the E.M.F. of a moderate battery of accumulators can be read with very fair accuracy. The authors have bestowed great care on the design of the needle, so that for a given potential difference the turning moment divided by the moment of inertia may be as great as possible. The whole instrument is protected from external inductive influence by having the inner surface of its glass case coated with a transparent conducting varnish, which Prof. Ayrton has described elsewhere.

Prof. Ayrton, also showed an idiostatic electrometer whose needle, instead of being suspended, was pivoted on an axle. The instrument is rapid and nearly dead-beat in action, and gives a scale-reading of about 3in. for an E.M F. of 100 volts.

Prof. S. P. Thompson expressed great admiration for the instruments exhibited, but denied that the law which they served to prove was Ohm's law at all, and this led to some discussion as to what Ohm's law really is.

Prof. Ayrton briefly replied.

THE RECENT EXPLOSION IN THE CITY.

In our last issue we reported the proceedings of the Board of Trade enquiry into the circumstances connected with the explosion which occurred in the City on the 10th inst. as far as it had been carried. The enquiry was resumed by Major Cardew on Friday last at Winchester House. Mr. R. W. Wallace (instructed by Messrs. Ashurst, Morris Crisp, and Co.) appeared for the City of London Electric Lighting Company, Limited; Mr. Russell Griffiths, for the Aldermen and City Commissioner of Police; and Mr. Baylis for the City Commissioners of Sewers.

Mr. T. G. Chesterman, M R.C.V.S., said that he made a *post-mortem* examination of the mare killed by the accident on the evening of the 10th inst., at the request of Mr. Boutland, its owner. He found nothing whatever to cause death. There was no appearance of congestion, and all the internal organs were perfectly healthy. He discovered no wounds, and he could not say, as the result of his examination, what the animal died from.

Major Cardew: Was there anything to indicate the passage of a current through the tissues of the body?

Witness: Nothing; and there were no signs of asphyxia. If he had not been told that the mare died from a shock, he should have been unable to account for its death.

Mr. H. Smith, foreman of cable mains to the City of London Electric Lighting Company, said he superintended the laying of the main from the Watling-street cable. The pipes were already in, and they had only to draw through the main, which was laid in lengths and connected together at junction-boxes. He was not present when the connections at the junction-boxes were made, that work being the duty of the jointing foreman. The main was in about 15 separate lengths from Watling-street to Bankside, the generating station, and each length was labelled. Replying to **Mr. Griffiths**, witness said it was his duty to see the mains left properly at each junction-box, and he did so in the present case. He satisfied himself that the right label was attached to each separate length of main. In answer to **Mr. Wallace**, witness stated that the labels, some of which were of linen and others of paper, were securely fastened with iron wire. Men going into the junction-boxes, however, might accidentally tear them off. He noticed that the tubes were crossed at some places, but that could not always be avoided.

Mr. Parrott, jointing foreman, said he superintended the jointing up of the Watling-street main. Each length was labelled, and the men jointed them up accordingly. Before any jointer got into a box to make the necessary connections he examined the labels, which were still there. He also examined each joint after it was made. Since the accident occurred he had traced the cable quite through, and had found that it was crossed with the Milk-street cable between the box in Maiden-lane and the box outside Edison and Swan's shop on the west side of Queen-street. In reply to **Major Cardew**, witness stated that when he jointed up the cables the labels were wrongly attached. Somebody must have made a mistake in putting the labels on. This was the only instance they had had of the kind. Replying to **Mr. Griffiths**, witness said the mistake must have been made in the labelling. When he traced out the cable on the day after the accident there were four or five men with him. The first examination in the junction-boxes of the cables was also made on that day. Nobody connected with the laying of the cable was with him when the inspection was made. He was positive that, according to the labels, the cables were properly connected. On the 13th the second engineer (Mr. Bates) examined the boxes at Thames-street and Queen-street, and saw the labels.

Mr. A. Cook, superintendent of cable-laying and of the transformer stations, said he gave the order for the jointing of the Watling-street cable to be performed, but he did not examine the labels before the work was proceeded with. He had been connected with electrical work for 12 years, and knew how to test a cable for continuity. Such a test would have revealed the existence of the fault. He was not present at the Watling-street station when the switching on of the new main took place, he having been occupied at Worcester Wharf in paying the men.

Major Cardew: Were you aware that the main was to be made alive?

Mr. Cook: Not of the exact time.

Major Cardew: But I suppose if you had so instructed the men it would have been deferred until you could have attended?

Mr. Cook: Well, we intended making it alive earlier in the morning, but they were not quite ready at Bankside. The foreman was left with instructions at Watling-street to make it alive on a signal from Bankside.

Major Cardew: Did you look into the arrangements for switching the main on?

Witness: Yes; they were the same as those on previous occasions for making a main alive. In answer to **Mr. Griffiths**, witness said he asked Mr. Peard, engineer of the testing department, whether he had tested the Watling-street main, and he replied he had made a rough test, and he then asked him if it were good enough to be put on, and he said yes. A note was here produced, written by Mr. Parrott to Mr. Peard, as follows: "Can Watling-street main be put in pillar? Wanted to be at work by 11 a.m." Mr. Peard's reply was: "The cable is good, but the final test has not yet been taken. Can go in pillar." The meaning of the phrase, "can go in pillar," was that the main was in a fit condition to be made alive.

Mr. Oliver Peard, electrical engineer in charge of the testing department, said the first he knew officially of a new main was on receiving a notification from the cable-jointing department, on a special form, that it was ready to be tested; and until he returned

Digitized by Google

a signed certificate as to the result of the testing to be made by him he was not responsible for any use made of the main. That was well understood. If a main were wanted in a hurry he would be informed of the fact, and would thereupon make a rough test to discover any fault in the insulation. The cable was then put into terminals provided for it at each end. The meaning of his words, "can go in pillar," was simply that the cable was ready for the final test, and not that it could be made alive. It ought not to be made alive until he returned his certificate guaranteeing that it was sound. In addition to the insulation test a pressure test was made, and subsequently the electrostatic capacity and the copper resistance of the main were taken. This series of tests occupied uncertain periods, but he had never made them under two days; and during that time, as far as he knew, the main being tested was never used.

Major Cardew: Mr. Cook told us that he asked you if the main were good enough to be put on, and that you said "yes."

Mr. Peard: That is not true. My reply was simply that I had made a rough test for insulation resistance, and that it was fairly good.

Major Cardew: You were aware the main was to be brought into work that day?

Mr. Peard: I did not think Mr. Cook would make a high-tension main of that importance alive when he knew that only a rough test had been made.

Major Cardew: Have you ever previously known a cable to be put to work before you had completed your tests?

Mr. Peard said he had not. There had never, so far as he knew, been any fault of insulation on the Benetfink main before.

Mr. Joseph M'Mahon, foreman of the transformer department, said he switched on the new main at Watling-street station on the 10th inst. Mr. A. Cook telephoned to the effect that he was to proceed to Watling-street station and wait for word from Bankside to switch on. He thought the main had been already charged. When he switched on he noticed after about a minute a kick in the lights. His orders had always been that the pressure should be on at Bankside first, and that the switching on should take place afterwards.

Mr. J. P. Buck, superintendent of conduits, and **Mr. F. H. Jackson**, engineer in charge of the generating station, having given formal evidence, the enquiry terminated.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Madrid.—Tenders are invited by December 8 by the Spanish Government for the construction of a telephone system at Santa Cruz, Teneriffe. Tenders are to be sent to the Ministère d'Outre Mer, Madrid.

Coventry.—The Corporation invite tenders from manufacturers for electricity meters. Particulars may be obtained on and after Friday, November 30, at the office of Mr. Robert Hammond, the consulting electrical engineer, Ormond House, Great Trinity-lane, London, E.C. Tenders to be delivered to Mr. Lewis Beard, town clerk, by Wednesday, December 12.

Enniscorthy (Ireland).—Tenders are invited for providing the Enniscorthy District Lunatic Asylum with internal telephonic communication, about 13 stations being required. Tenders will be considered by the Board on December 12, and should be sent, addressed to the chairman, so as to reach the asylum by 6 p.m. on December 11. Furthers particulars can be obtained from the resident medical superintendent.

Blyth.—The Cowpen District Local Board (Blyth, Northumberland) invite tenders for the efficient lighting, by electricity or otherwise, of the lighting area within their district for a period of seven or ten years respectively, commencing from August 15, 1895. A plan of the district can be seen and further information obtained at the Surveyor's Office, Commercial-buildings, Waterloo, Blyth. Tenders, endorsed "Lighting," to be sent to Mr. Robt. T. Guthrie, clerk to the Board, not later than December 20.

London, N.— Tenders are invited for the supply of new and the purchase of old stores for 12 months from January 1, for the Great Northern Railway Company. A list of the contracts, and separate forms of tender for each contract, may be obtained on application to Mr. Martin, stores superintendent, Doncaster, by whom every information will be furnished. The stores must be in every case equal in quality to the company's sealed samples and patterns, which will be exhibited in the Stores Department, Doncaster, where they may be inspected, on application to the stores superintendent, from now until December 7 between 10 a.m. and 4 p.m., and the contractors are requested to call and examine them before tendering. N.B.—The patterns of telegraph and electric lighting material will be exhibited at the Telegraph Stores, Retford. The company's samples and patterns cannot be sent to contractors for inspection. Tenders, addressed to the Stores Committee, marked on the outside with a description of the stores tendered for, must be sent to the company's offices, at King's Cross, in the envelopes specially provided, so as to be received by 10 a.m. on December 8. Mr. William Latta, secretary.

RESULTS OF TENDERS.

London, W.C.—Thirty-four tenders were received for the Salisbury Estate electric lighting, the totals for the whole job varying from £5,437 to £8,473. The lowest tender was from Messrs. B. Verity and Sons, who offered a combination of Edwin Danks's dry-back boilers and Parsons turbines, and made stronger guarantees than any other tenderer in reference to the absence of vibration. The contract has accordingly been allotted to them.

St. Pancras.—The Vestry have received the following tenders for supplying and laying armoured cable mains:

W. T. Henley's Telegraph Works Company, Limited (accepted)	£17,104 16 3
Callender's Bitumen, Telegraph, and Waterproof Company, Limited	17,817 16 7
Alternative tender	17,760 6 7
Siemens Bros. and Co., Limited	18,581 7 9
Fowler-Waring Cables Company, Limited	18,645 13 4
British Insulated Wire Company, Limited	18,848 19 3
India Rubber, Gutta Percha, and Telegraph Works Company, Limited	23,650 19 5
Alternative tender	21,713 13 8
W. T. Glover and Co.,	25,767 7 8
Alternative tender	22,331 3 2

For the extension of the underground sub-station, the tenders were:

J. Steed (accepted)	£208 16 9
J. O. Richardson	226 12 5
C. W. Killingback and Co.	244 7 5
J. Mowlem and Co.	284 0 10

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £3,415.

Glasgow.—A new Conservative club was opened yesterday (Thursday) in Bothwell-street. It is lighted electrically.

Burton.—Mr. Codrington, R.E., has held an enquiry into the application of the Town Council to borrow £53,000 for various purposes, including electric lighting.

Newcastle.—The foundation-stone was laid yesterday (Thursday) of the new John Knox Presbyterian Church in Elswick-road. It is intended to light it electrically.

Brazilian Submarine Telegraph Company. — An interim dividend of 3s. per share has been declared by the Board for the quarter ended September 30, payable on December 21.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 25th inst. amounted to £913, as compared with £580 in the corresponding week of last year.

Sale.—The Brighton and Hove Electric Light Company, Limited, announce for sale the whole of the plant, machinery, and stock at Brighton. Particulars will be found in our advertisement columns.

Aberdare.—A meeting of the promoters of the proposed company to provide for the electric lighting of Aberdare has been held at the Boot Hotel, and arrangements were made for the formation of the company.

Croydon.—Councillor Dr. Hobson has suggested to the Croydon County Council that incandescent gas lamps should be used in streets which would "in all probability not be benefited by the proposed electric light."

Leamington.—Alderman R. Eardley Wilmot, who has presented a report on the last year's work at the pump-room, pointed out that among the improvements decided upon last March was a new electric light installation.

Ayr.—The Town Council have unanimously agreed to remit to a committee, with powers, the completion of the purchase for £1,000 of a site in Mill-street, abutting on the river, as the central station for the electric light.

Olympia.—The London County Council have approved of plans for alterations on the ground level of the large hall at Olympia, provided the four divisions in the palace be enclosed and be lighted with the electric light.

Worcester.—The new Electricity Committee of the Town Council comprises the Mayor, the Deputy-Mayor, Aldermen Hill, Ernest Day, and W. Holland, Councillors Cock, W. Caldicott, H. Day, Chaplin, and Millington.

International Trade Exhibition, Limited.—This Company has been registered, with a capital of £2,000 in £1 shares, to establish and carry on the business of exhibition promoters, restaurateurs, advertisement contractors, and caterers.

Hampstead —The Metropolitan Asylums Board have approved of the draft agreement with the Vestry of Hampstead for the supply for three years certain of electrical energy to the North-Western Hospital at 4d. per Board of Trade unit.

Home Telephone Company, Limited.—The creditors of the above-named Company are required, on or before December 14 next, to send in their names and addresses, and the particulars of their debts or claims, to Mr. E. A. Horne, 85, Queen Victoria-street, London, E.C., the liquidator of the Company.

City and South London Railway.—The receipts of the Company for the week ended November 25 were £957, against £897 for the corresponding week of 1893, or an increase of £60. The total receipts for the current period of the present half-year amount to £18,648, as against £17,370 in the corresponding period of 1893, an increase of £1,278.

Islington.—The Vestry have received a deputation from the Islington Board of the Independent Labour party with reference to the provision of work for the unemployed during the ensuing

Digitized by Google

winter, and in connection with the installation of the electric light in the parish. The Works Committee are to present a report on the subject.

Newcastle.—A meeting of Newcastle City Lighting Committee was held on Tuesday, when Mr. J. Barker Ellis was re-elected chairman, and Mr. W. J. Matthewson, vice-chairman. It was proposed by Mr. T. Waller, and carried, that two new electric lamps be erected, one at the bottom of Picton-place and the other at the east end of Byker Bridge.

Williamson Electrical and Engineering Company, Limited.—Notice is given that a general meeting of the members of the above-named Company will be held at Temple-chambers, 33, Brazennose-street, Manchester, on December 17, for the purpose of having an account laid before them showing the manner in which the winding up has been conducted.

Granada Railway Company, Limited.—This Company has been registered with a capital of £300,000 to construct, equip, and maintain railways, light railways, tramways, wire, electric, pneumatic, water, or other powers, telegraph and telephone lines and works, and any means of communication, connection, and propulsion in the kingdom of Spain or elsewhere.

Bournemouth.—The trustees of the Punshon Memorial Wesleyan Church are considering a scheme for lighting the church by electricity. The Town Council have received a letter from the Secretary of the Board of Trade stating that the promoters of the Poole and Bournemouth Tramways Company have been granted an extension of time till August 4, 1895.

Dundee.—The Gas Committee of Dundee Town Council have received an application from Messrs. Jaffe Bros., jute merchants, to have their establishment in Seagate illuminated with electric light. The engineer reported that the mains would require to be extended in Seagate to give effect to the request, and this he estimated would involve an expenditure of £135. It was agreed that the request should be granted.

Chiswick.—The surveyor to the Local Board has submitted plans of the extra ground required at the electric lighting station, the area being 72ft. On the proposal of Mr. Hunt it was decided to allow the use of this ground for the works. In reply to a letter from the Board, Messrs. Bourne and Grant wrote stating that the work should be pushed on with all expedition after the Board had decided to allow them the necessary land.

Electric and General Investment Company, Limited.—We are informed that the directors have declared an interim dividend on the capital paid up on the ordinary shares of the Company at the rate of 10 per cent. per annum for the six months ending November 30, 1894, the dividend to be payable on and after December 20 next. The transfer books of the company will be closed from December 6 to December 20 inclusive.

Conversion of Firm.—Messrs. Nalder and Harrison inform us that they have formed their business into a limited company, trading under the name of The Nalder and Harrison Construction Syndicate, Limited, in order to increase the capital sufficiently to cope with the large amount of work they have now in hand. The business will be carried on under the same management, and the shares are being privately subscribed for by the directors and their friends.

An Interesting Model.—Mr. John G. Masson, stamp and die cutter, South Constitution-street, Aberdeen, who has gained many prizes for expert workmanship, has just completed an exceedingly ingenious model which he intends to enter for competition for a prize of £20 offered by a popular London weekly. The subject of the model is "The Village Smithy." The model is lighted by electricity. A small battery gives a light of 1½ c.p. The battery is sufficient to give light for nine hours.

London.—Messrs. Rashleigh Phipps and Co. have received the contract for the electric lighting of Mr. Frank Wyatt's new house in Queen's-gardens, and also for Mr. J. A. Mitchell's new restaurant in Princes-street, and the offices of the National Assurance Company of Ireland in Nicholas-lane. They have also just completed the lighting of the Wimpole Hotel, Wimpole-street, and Limmer's Hotel, George-street, Hanover-square, and are very busy with electric lighting several private houses, etc., in the West-end.

Cassel Gold Extracting Company.—The directors have resolved to pay a dividend of 5 per cent. in cash, together with one share each in the African Gold Recovery Company, Limited, and the Australian Gold Recovery Company, Limited, for every 20 fully-paid shares held in the Cassel Company, and one share in the New Zealand Crown Mines Company for every 40 fully-paid shares held in the Cassel Company, all free of income tax; two of the third issue of Cassel shares, with 10s. each paid, to be counted as one fully-paid share.

Brighton.—On the proceedings of the Lighting Committee at a meeting of the Town Council, Councillor Wishart complained of the prolonged obstruction of Church-street by excavations for electric lighting purposes. Councillor Stafford promised that the work should be pushed forward as rapidly as possible. Replying to Councillor Daniel, Councillor Stafford said the committee could not see their way to give additional light in Meeting House-lane, as the two lamps there were 90ft. apart, whereas the regulation distance was 150ft.

Wolverhampton.—Alderman Gibbons at a meeting of the Town Council presented a complaint with regard to the taking up of the footway in narrow streets on market days to place the electric light in shops. He thought the work should be done with less inconvenience to pedestrians. The Mayor said the obstruction which had been caused should not occur again. The following have been appointed members of the Lighting Committee of the Town Council: the Mayor, Aldermen Dickenson, Jackson, and S. T. Mander; Councillors Allen, Craddock, Ironmonger, Jenks, Johnson, McBean, Pinson, Shepherd, and J. J. Tate.

Litigation.—In the Chancery Division on Friday last, before Mr. Justice North, the Electrical Power Storage Company, Limited, and the Electric Construction Company, Limited, were plaintiffs in an action against the Chloride Electrical Storage Syndicate, Messrs. Mather and Platt, and Mr. John Hopkinson. Sir Richard Webster moved to restrain an alleged infringement of what he called the great patent for secondary batteries. The patent, which had been extensively used, was now 13½ years old, and would expire in May next, so that time was of the essence of the matter. The defendants not being ready with their affidavits, the motion was ordered to stand over till Thursday next week.

Manchester.—The City Council have been considering the question of the gas management, and incidentally Mr. Alderman Higginbottom, deputy-chairman of the Gas Committee, pointed out that four years ago the Gas Committee suffered under one great disadvantage. They then had to face the introduction of the electric light into Manchester. That suggested a formidable rival to gas, and the committee were afraid of launching out and spending a large capital in improvement when their revenue seemed likely to diminish. The experience of London and other places showed there was no ground for fear, and so of late the committee had spent large sums in extending and remodelling their works.

Municipal Installations.—Blackpool's electric lighting system has, says the *Blackpool Gazette*, received a lot of attention from other corporate bodies who are desirous of lighting up their respective towns by similar means. There may have been a lack of foresight in making the local installation, but this is compensated for in other directions, I take it. Anyway, there is little doubt that peregrinating deputations, picking up information and having an enjoyable pleasure tour at the expense of the ratepayers, are generally very favourably impressed with what they see at Blackpool. The Mayor of Harrogate, the ex-Mayor (Alderman Fortune), and other members of the Harrogate Town Council have visited us, and were conducted over the works in West Caroline-street by Mr. Hesketh. At night all the lights upon the Promenade were turned on for the benefit of the deputation, who afterwards foregathered with local councillors at the Winter Gardens and Opera House.

Wigan.—Notice has been given by the Wigan and Districts Tramways Company, Limited, of an application for a provisional order for the construction of new tramways in the districts of the Hindley and Ince-in-Makerfield Local Boards and the borough of Wigan. It is provided that the company may use horse, steam, mechanical, or electric power. The clause runs: "To empower the tramways company and their lessees to work the intended tramways by electricity, steam, or any other motive power, and partly by one power and partly by another, and to authorise the tramways company and their lessees to erect, place, make, and maintain works, engines, machinery, dynamos, and apparatus for the production, storage, and supply of electricity or other power, and to lay down and construct mains, wires, pipes, conductors, apparatus, and things necessary or proper for the transmission of electricity or other power, and the working of the intended tramways, or any of them, by electricity or other power."

Harrow.—The Governors of Harrow School have intimated to the Harrow Local Board their willingness to favourably consider a proposal for lighting the school chapel, library, and other school buildings, provided they had full estimate of the cost. The Board's engineer offered to estimate at 5 per cent. if the work was carried out, and 2½ per cent. if it was not carried out. The headmaster of the school would not pledge himself to this expense, so the Board decided to ask 10 good firms for tenders. Eight were sent in, and the committee having charge of the matter sent up two of those tenders to the Board for consideration. These were from the Brush Company and from Messrs. Crompton. The Board accepted Messrs. Crompton's provisionally, and it was announced it amounted to £8,762 for plant, etc., and £1,686 for maintenance, as against the engineer's estimate of £9,300 and £2,092. The Board expressed themselves exceedingly satisfied, the estimate of the accepted firm being so close to that of their electrical engineer.

Luton.—The following resolution has been passed by the Town Council: "That application be made to the Board of Trade on or before December 21, 1894, for a provisional order empowering the Mayor, Aldermen, and Burgesses of the borough of Luton to supply electricity for public and private purposes within the said borough, in accordance with the provisions of the Electric Lighting Acts, 1882 and 1888, and the rules made by the Board of Trade relative thereto under the said Acts; and the town clerk and parliamentary agents are hereby authorised to give all notices and do all other acts and things necessary and legal to complete and finally obtain the said provisional order; and, further, that the memorial to the said Board of Trade, so soon as prepared, be sealed with the common seal of the Town Council, and duly signed by the Mayor and town clerk." Considerable discussion took place on the proposed compulsory area, and it was ultimately decided that the area be George-street, Market-hill, Park-square, Cheapside, King-street, Upper George-street, Wellington-street to Stuart-street, and Bute-street.

Llandudno.—Messrs. Dickenson and Co., Darlaston, have written to the Improvement Commissioners enclosing plans of an electric tramway they propose to construct along the shore of the Conway Bay from Deganwy to Llandudno. The Deganwy Estate Company have approved the scheme, and the promoters

Digitized by Google

sought the approval of the Board. Mr. Elias Jones moved, and Mr. Bevan seconded, that the plans be referred to committee. Mr. Jones (Cedars) moved that the Board approve the principle of the scheme that day, without committing themselves to details. The scheme would develop the erection of residential property on the Conway shore, and ought to have commenced years ago. People would be able to come from Deganwy shopping to Llandudno in a quarter of an hour. Surely Llandudno tradesmen would not object to that. Mr. J. Owen seconded. Mr. Elias Jones saw no reason for such a great hurry. They were not opposed to the scheme, but it should be reported upon first. Several members thought it would facilitate matters if the principle of the scheme were approved that day, and eventually the amendment of Mr. Jones (Cedars) was carried by the casting vote of the chairman.

Westminster Electric Supply Corporation, Limited.—An extraordinary general meeting of this Company was held on Wednesday at the office, Eccleston-place, Belgravia, Mr. J. H Powell presiding, in the absence of Lord Suffield (chairman of the Company). The Chairman formally moved resolutions to the effect that out of the newly-created share capital of £100,000, £40,000 in 8,000 shares of £5 each be forthwith issued at a premium of £1 per share, and in the first instance be allotted to shareholders on the register on the 14th inst., in the approximate ratio of one to every completed eight shares then held; that the amounts due on the shares be payable as follows: £1 (premium) on January 3, 1895, £2 on January 15, 1895, and £3 on July 1, 1895, the new shares to rank for dividend (on amount of capital paid) from January 1 next; and that the balance of 12,000 shares be retained until such time as the Board deem it desirable to issue them. Mr. E. Boulnois, M P., seconded the resolutions, which, after a complaint from Mr. Tooth that the shares were not offered to the shareholders at par, were agreed to unanimously.

The Rhondda.—At the fortnightly meeting of the Rhondda Local Board the clerk read letters he had received from various colliery companies in respect to the proposed scheme to light the valleys by electricity. Messrs. Cory Bros., Cardiff, stated they had no supply of electricity to spare at the Gelli colliery, but at the Pentre collieries they could afford to supply the Board with 50-c.p. lights. As they were not accustomed to supply electricity to outsiders, it would be difficult for them to furnish terms. The company were prepared to give further consideration to the scheme. If the Sanitary Authority would grant a license for supplying the district generally, the company might be disposed to consider a scheme for laying down an additional installation to light the streets as well as the houses. Messrs. D. Davis and Sons, Ferndale, replied that they would give the scheme their consideration, and would forward their views to the Board in a few days. The Glamorgan Coal Company, Llwynypia, enquired whether the Sanitary Authority desired them to lay down cables, and what number of lights were necessary. After receiving full particulars of the scheme the company would be able to give a definite reply.

Leigh.—The Local Board have held a meeting, at which the chairman said that application had to be made to the Local Government Board for a provisional order for the extension of the gas-works during the month of November. Application had also to be made to the Board of Trade for a provisional order to supply electricity in the Local Board district within the month of November. All the details with respect to the introduction of the electric light would have to be fully considered hereafter. At the present time they had merely to pass a formal resolution to apply to the Board of Trade for a provisional order. The Gas Visiting Committee had been to Nelson, Lancaster, Morecambe, and Blackpool, and had also made enquiries elsewhere, and they were of opinion that the time had now arrived when the electric light ought to be supplied to Leigh; and they had reason to believe that there would be an adequate demand to justify them in introducing it to Leigh. He then formally moved, and Mr. R. Guest seconded, the following resolution which was carried unanimously: "That the report, dated November 13, 1894, of the Gas Visiting Committee, now produced and read, having reference to the supply of electric lighting within the Leigh urban sanitary district, be approved and adopted, and that the clerk be authorised to make application to the Board of Trade for a provisional order to supply electricity within the Leigh urban sanitary district under provisions of the Electric Lighting Acts, 1882 and 1890."

Dover.—It has been reported by the town clerk that the electric light company had paid their account for August, but the accounts for September and October were outstanding. The Chairman remarked that he thought the company should pay more promptly, the gas company would not want such long credit. Notice was received from the electric light company of their intention to continue their mains as far as Buckland Church, it having been decided to adopt the light in that church. A letter was read from Mr. Lawson, the engineer to the company, suggesting that as men expecting the work of fixing street lamps and laying mains were in the town, the light of the streets by electricity should be continued to the Town Hall. A memorial very extensively signed was also received from the inhabitants of Biggin and Cannon-street making a similar request. Councillor Finnis expressed his opinion that they ought to wait until the street was widened before going into the matter. The Chairman said he could not see that there was any objection to light Cannon-street. Councillor Barnes moved that the matter should stand over for a week. Councillor G. Mowll said he did not see how the Town Ward Lighting Committee could report until, the street was widened, as to the lamps required. Alderman Peake said that the complaint as to the street being badly lighted did not originate from any fault on the part of the gas company, but because the Council had not expended enough to light the street properly. They were open to compete with the electric light company so far as light was concerned. The matter was allowed to stand over for a week.

Edinburgh.—The Lord Provost has stated in a speech to the Town Council that the scheme for lighting the city by electricity would soon be completed, and he thought the Council was very much indebted to the convener of the sub-committee for the energy he had shown in carrying out the mandate of the Council. He trusted that the citizens would take kindly to the new light and become good customers of the town. In his opinion the introduction of the electric light would not affect in any degree the consumption of gas, provided, of course, the Gas Commissioners charged a popular price for it. There was plenty of scope for gas, not only as a heating agent, but also as a motive power. Messrs Mackenzie and Cranston gave notice of a motion to remit to the Lord Provost's Committee to consider and report as to whether it is desirable at this stage to arrange for laying down electric light high-tension cables from the station to Nicolson-street for the purpose of supplying domestic lighting through transformers. The Town Council have resolved, on the motion of Bailie Anderson, seconded by Mr. Hunter, to remit to the Lord Provost's Committee to consider and report as to which mode of tramway traction the Council should adopt in view of a change, wholly or partially, to mechanical power. The Electric Light Committee of the Edinburgh Town Council have agreed to supply electric current for the lighting of the M'Ewan Hall and the Medical School, New University, and also to give a supply to large business premises, called the Globe Mart, at the top of the Canongate. The supply is granted on the usual terms, that a certain amount of current is taken for three years. These buildings are outside the compulsory area.

Cardiff.—A special meeting of the Lighting and Electrical Committee of the Cardiff Corporation was held on Friday last at the Town Hall, Cardiff, the Mayor (Alderman Carey) presiding, for the purpose of making a primary selection of candidates for the post of electrical foreman at the Cardiff electric lighting works, the salary of which is £3 per week. The candidates selected to appear before the committee were Philip Peter, St. John's, Worcester; Thomas J. Archer, Chelmsford; and Charles H. Yeaman, Victoria-street, Westminster. Messrs. Leaf and Co. are now engaged fitting the new Aberdare Hall for the electric light. Mr. Harpur, the borough engineer, has told an interviewer that although meters for private consumers had been ordered some months ago, they have not yet been supplied. In consequence of this, a new scale of charges has been drawn up which it is intended shall remain in force until such time as meters can be obtained. The new scale is as follows:

Per lamp per annum. s.	d.	C.P. lamp.
15	0	8
22	6	16
34	0	25
45	0	32
66	0	50
113	6	100
227	0	200
340	6	300
		Watt arc lamp.
100	0	250
200	0	500

In lieu of a rate of payment of 6d. per Board of Trade unit as agreed in the requisition. For private residents and offices the charge will be one-third less.

Snowdon.—It was originally intended that the ceremony of cutting the first sod of the Snowdon electric railway would take place on Dec. 5. Owing to unforeseen circumstances this function has been postponed until December 15. The following letter has appeared in the *Times*: "Sir,—If I am not boring you about a matter which has already occupied much of your space, I should like, failing a better man's pen, to deal very briefly with the *altera pars*. Having known the Snowdonian district for 30 years, I am well aware how much the attractiveness of the great mountain could be increased by giving the 'old man in a hurry,' the middle-aged one, and the young facilities for ascending to heights sublime without the laborious walk of five miles from base to summit. No pedestrian would be robbed of his walk by the making of a funicular or other railway, and only one side of the giant hill would be disfigured. In all cases of this kind it is 'Arry who is dreaded, and he only is thought of; there are, however, many scholars and men of business and others with scant holidays who would make the ascent if only Snowdon were treated like Vesuvius, the Rigi, and Pilatus; and I feel confident that neither a cultured man like Canon Rawnsley nor more homely lovers of grand scenery need fear anything from the multiplication of excursionists, male and female, learned and ignorant, serious and frivolous. I made the ascent years ago on foot without a guide, being then what a Welshman called a good 'pedestinarian,' and I should like the glories of the mountain to be enjoyed by those whose holidays and breath are alike short. These latter look to wheels to help them, and I trust that the wheels will be forthcoming ere long.—Very truly yours, R. St. J. Corbet, St. Mary's-place, Shrewsbury."

South Staffordshire Tramways Company.—Justice Williams has had before him the petition of Smallman and others for a winding-up order in the matter of the South Staffordshire Tramways Company. Mr. Parker, for the petitioner, said the Company

Digitized by Google

did not dispute, but asked for an adjournment. The assets were in the hands of a receiver and manager appointed by Justice Kekewich, and the action was coming for trial before Justice Kekewich in Chancery. His Lordship asked what was there to try? Mr. Parker replied that the point had been taken, and Justice Kekewich was now of opinion that he had not jurisdiction to appoint a manager, but only to appoint a receiver in this as a going concern. In that case the Company would be able to pay off these creditors, who were trade creditors. Mr. Stuart Smith, for the Company, and Mr. Levitt, Q.C., for the largest creditor, the Electric Construction Company, agreed to an adjournment. His Lordship said the case must stand over for a week. The case of Marshall *v.* the South Staffordshire Tramways Company, Limited, has been before Mr. Justice Kekewich in the Chancery Division, on the motion for judgment. Plaintiffs, who are the holders of debentures, asked for a declaration that mortgage debentures issued by the Company and its predecessors in title, and now outstanding, constitute the first charge on all the undertaking and property of the Company for an account of which is due and owing to plaintiffs—viz., principal, interest, and costs; and also to have a receiver and manager of defendant Company's undertaking included in the said debentures. At the conclusion of the arguments of counsel his Lordship held that the plaintiffs had no ground whatever for asking for a manager, and the only thing they were entitled to was the appointment of a receiver to make proper enquiries.

Bristol.—The chairman of the St. George's Local Board has informed the Board that a private company was seeking powers to light the parish by electricity, and he submitted to them whether they ought not to obtain such power, and then they would be in a position to use it if required. They ought not to give themselves to a private corporation without defending themselves to some extent. It was agreed to leave the matter to the new body to be dealt with. There was a large attendance at the meeting of the Electrical Committee of the Town Council on Saturday, all the members being present with the exception of Alderman Proctor Baker—viz., the Mayor, Alderman Pethick (high sheriff), Messrs. Bastow, Board, Hill, Hughes, Lloyd, Pearson, Pembery, Tryon, and Wills. The secretary having read the formal appointment of the committee, the Mayor proposed, and Mr. Charles Wills seconded, that Mr. George Pearson be appointed chairman for the ensuing year, and the motion was carried unanimously. On the motion of Mr. Pearson, Mr. Stephen Tryon was appointed deputy-chairman. The chairman, deputy-chairman, Alderman Pethick, and Mr. Hughes were appointed a sub-committee for finance for the ensuing year. The secretary reported the result of the circular letters to the occupiers of premises in St. Stephen-street, and the committee determined not to make the extension at present. Applications for a short extension along Percival-road, Clifton, were considered, and the committee determined to make the extension on the usual agreements, guaranteeing a minimum consumption, being entered into. Applications for an extension to Pembroke-road were considered and declined. An application for an extension to Victoria-square, Clifton, was reported, and the secretary was directed to send a circular letter to the residents of the west side of the square, with the view of ascertaining the amount of support the undertaking would receive in the event of an extension being made.

Asylum Lighting.—Messrs. Ernest Scott and Mountain, Limited, Newcastle-on-Tyne, send us particulars of the electric lighting installation carried out by them at New Craig House, Morningside, Edinburgh, to the order of the Managers of the Royal Edinburgh Asylum for the Insane. There are two steel Lancashire boilers, each 25ft. long by 7ft. 6in. in diameter, of a working pressure of 140lb. per square inch. These supply steam to four compound horizontal steam-engines, each capable of developing 60 h.p., for driving four dynamos — one engine being a spare. The engines are each fitted with cylinders of the following diameters: high pressure 8½in. diameter, and low pressure 14½in. The stroke is 16in. The engines are each constructed to run at a speed of 150 revolutions per minute. Four dynamos are provided of Messrs. Scott and Mountain's improved type, each machine being constructed to give an output of 240 amperes at 105 volts. The speed is approximately 700 revolutions per minute. The dynamos are belt driven. The installation is divided into 12 main circuits and a large number of sub-circuits. The whole of the cables used throughout the installation are highly insulated with vulcanised indiarubber, the minimum insulation resistance being 600 megohms per statute mile, but from careful tests taken by the consulting engineer, it has been found that the insulation of the whole of the building is extremely high; all cable is run in continuous wood casing, fitted with a moulded cover secured by brass screws. Great consideration has been given by the architect and consulting engineer to the class of switch most suitable for an installation of this kind, and the switches throughout are of a special type, the object being to prevent the patients interfering with them or switching on the lights. The switches in the main corridors, and in all positions where they could in any way be tampered with by the patients, are all of the sunk type, of solid brass, the face of the switch lying flush with the wall, and the switch can only be put on or off by a special key kept by the attendant. The whole of the work in connection with the lighting of the house has been carried out under Mr. W. A. Bryson, M.I.E.E., consulting electrical engineer, Glasgow, and Messrs. Sidney Mitchell and Wilson, architects, Edinburgh.

Coventry.—The General Works Committee of the Town Council have reported that in the agreement made April, 1893, between the Corporation and Mr. Graff Baker with respect to the equipment of the tramways, it was provided that if before September 30, 1893, the undertakers shall not have equipped the tramways upon the Thomson-Houston overhead system, the Corporation might require the tramways to be so equipped within three months from the date of such notice, and if after the expiration of such three months the tramways shall have not been so equipped, either party to the agreement might determine the same. No part of the tramways was equipped on September 30, 1893. After various postponements, the committee had received another letter stating that a gentleman interested in the matter was expected from New York, and asking that the matter may be again postponed until his return. The committee considered, however, that no more delay should take place, and recommended that notice be given to the proprietors of the tramways requiring the tramways to be equipped within three months. Alderman Marriott moved the adoption of the report, and said the whole subject had given the committee a vast amount of trouble and much anxiety. He thought every member must be pretty well satisfied that it was high time something was done to bring the matter to a conclusion one way or another. Either Coventry ought to have the tramways properly equipped and worked, or if that were not done, the rails should be removed. He was not one to advocate their removal—although in the first instance he was not a great advocate for tramways being laid—as the public had much appreciated them. It was the Council's duty to see that no more time was lost in getting them into proper order. Nearly two years had elapsed since the trams ceased to run, and sufficient time had been given to the owners. Time after time they had applied for extensions, and he thought nothing had been wanting on the part of the Corporation. The last communication made to them was that some gentleman was about to leave America. It was not said whether he was coming here or going to Australia, or what he intended to do. At any rate, it was high time the Council knew what all this was about, and he had great pleasure in proposing the adoption of the report. Alderman Singer seconded the adoption of the report, and it was carried unanimously. The corporate seal has been affixed to a mortgage of the general district fund for £300 at 3¼ per cent. for the electric light.

Ealing.—The Electric Lighting Committee of the Local Board have reported that a letter had been received from Mr. C. Shepheard, J.P., in which he stated that the electric lighting of his house in Grange-road had given great satisfaction. Messrs. Penny and Co. had written intimating their intention to wire five houses they were about to erect in Montpelier-road. Messrs. Bramwell and Harris, the engineers to the Board under the scheme, wrote that they were unable to ascertain with whom the fault lay that the work of laying the electric light mains in the Uxbridge-road towards the Acton boundary had been proceeded with in disregard of a resolution of the Board and of the instructions conveyed by them to the contractors in pursuance of that resolution. Mr. St. John thought that this letter was very unsatisfactory, and the Chairman expressed a similar opinion. The surveyor reported that, including applications from the Drayton Court Hotel and the three adjoining shops, and one from the High-street (which applications had just come to hand), the number of private 8-c.p. lamps applied for was 3,580, out of the 5,000 that at the inauguration of the scheme it was computed would be required by private residents; that number of lamps applied for was included in some 58 applications. Thirty-eight of these applications had been complied with by the connections being made; five other connections would be completed in the present week, and others, it was expected, would be finished in the course of the following week. The Surveyor added that he would be much mistaken if by March next the full number of 5,000 private lamps were not applied for, and the record in this matter for all England be thus broken. The Electric Lighting Committee, in their report, stated that the question of the extension of the mains for the purposes of private lighting had been considered by them, and was again deferred pending the signing of forms of application by the residents of the Mount Park district and tradesmen on the Haven Green-parade who had signed the memorial presented to the Board, and asking for the introduction of the light into that locality. Mr. Baker Hays urged that the Board should at an early period consider the question of extending the mains to, at any rate, the Haven Green-parade (for the accommodation of the shops there) and Woodville-road, if not beyond, into the Mount Park district. He pointed out that an increased private consumption of the light meant an additional revenue to the Board, with a consequent reduction of the cost of the street-lighting, and also of the rates; and whilst not formally moving on the present occasion any resolution on the subject, urged that the Board should take an early opportunity of letting the residents in the Mount Park district know that the Board had absolutely a definite intention of introducing the light into that district. When that intention was made known, Mr. Baker Hays asserted, signed agreements from residents to use the light would be readily and numerously obtained. Mr. Tidy thought that before proceeding to consider any extension of the electric area the Board should first have completed the works in the present area, as regarded repairs to the footpaths necessitated by the laying of the mains and the erection of the lamps that were not at present put up along the Uxbridge-road; there was, he said, plenty of work to do in connection with the present part of the scheme before any extension of the work was resorted to. Mr. Baker Hays responded that the matters to which Mr. Tidy had referred related to past history, and were matters of detail with the contractors; the proposed extension of the mains for the purposes of private lighting in other parts of the district was a matter of future work. The subject was not further pursued.

PROVISIONAL PATENTS, 1894.

NOVEMBER 19.

22302. **Improvements in chairs for electric tramways, underground channel or conduit.** John Wilkinson, 27, Rawcliffe-street, South-shore, Blackpool.

22303. **Improvements in arc lamps.** Victor Henry Coates, Lagan Foundry, Belfast.

22325. **Improvements in safety and distributing fuses for electric light wire and for other purposes.** Ralph Gooch Tyler, 5, Crown-court, Cheapside, London.

22310. **Improvements in and relating to multipolar dynamo machines.** George Leonard Addenbrooke, 433, Strand, London.

22341. **Improvements in connection with the pickling of articles with the aid of electricity and apparatus therefor.** William Stepney Rawson and Woodhouse and Rawson United, Limited, 74, Coleman-street, London.

NOVEMBER 20.

22394. **Electric liquid level indicator.** William Blenheim, Station-road, Egham.

22403. **Improvements in and connected with steam-engines for driving dynamo-electric machines.** James Weir and James Gilmore Latta, 87, St. Vincent-street, Glasgow.

22453. **Improvements in the manufacture of insulated electric conductors and in the method of and apparatus for producing the same.** John Robinson, Norfolk House, Norfolk-street, London. (Complete specification.)

22458. **An improved electrically-propelled carriage.** Frank King, 47, Lincoln's-inn-fields, London.

22460. **Improvements in or connected with electrically-propelled vehicles for common roads.** Frank King, 47, Lincoln's-inn-fields, London.

22465. **Improvements in electrical switches.** William Thomas Burbey, 77, Chancery-lane, London.

NOVEMBER 21.

22486. **A sheet, card, or book, with alphabetical spaces or divisions containing names, numbers of telephone, and address of clients or customers, for telephone renters' use.** Sydney Buckthought, 53, Arcade-chambers, St. Mary's-gate, Manchester.

22517. **Improvements in commutator brushes for dynamo-electric machines.** William Begg, 62, St. Vincent-street, Glasgow.

22521. **Improvements in electric gas-lighters.** Axel Orling, 4, Corporation-street, Manchester.

22531. **Improvements in and connected with resistances and switches for electric circuits.** Michael Holroyd Smith, 55, Chancery-lane, London.

22547. **Improvements in electrodes applicable for use in electric accumulators and other electric apparatus.** Alexander Emil Hugo Honrichs, 191, Fleet-street, London. (The Firm of Hirschwald, Schäfer, and Heinemann, Germany.)

NOVEMBER 22.

22613. **Improvements in or relelating to the electro-chemical decomposition of solutions of salts.** James Charles Richardson, 19, Claremont-square, London. (Complete specification.)

22615. **Method of and apparatus for illumination by means of combustible gas with forced supply produced by electrical energy.** Louis Denayrouze, 28, Southampton-buildings, Chancery-lane, London.

NOVEMBER 23.

22700. **Improvements in accumulators.** Auguste Lesquoy, 70, Palace-chambers, Westminster.

22718. **Improvements in or relating to electric motors.** Alfred Julius Boult, 323, High Holborn, London. (Emmanuel Depoux, France.)

NOVEMBER 24.

22270. **Electrically-illuminated timepiece.** George Ashford, Montefiore, Caerleon-road, Newport, Mon.

22779. **Improvements in phonographs.** Joseph Oulton, 2, Market-street, Bradford.

22819. **Improvements in lock and block electric apparatus for railways.** Edward Tyer, 28, Southampton-buildings, Chancery-lane, London.

22821. **Improvements in conduits for electrical conductors and in the mode of making same.** James Tatham, 28, Southampton-buildings, Chancery-lane, London.

22824. **Short-circuiting device for stopping dental motors.** Francis Napier Denison, 4, South-street, Finsbury, London. (Complete specification.)

22826. **Improvements in the treatment of solutions of zinc chloride for the purification thereof for electrolytic purposes.** John Brock, Arthur Edward Waring, and Ferdinand Hurter, 47, Lincoln's-inn-fields, London.

22827. **Improvements in and relating to the treatment of solutions of chloride of zinc for the purification thereof for electrolytic purposes.** James Brock, Arthur Edward Waring, and Ferdinand Hurter, 47, Lincoln's-inn-fields, London.

22802. **Automatic electrical wonder.** William Frank White, 41, Meyrick-road, Clapham Junction, London.

22842. **Improvements in automatic circuit breakers for electric currents.** Jean Lorwa and Pierre Feys, 45, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1881.

129.* **Galvanic batteries.** Johnson. (Faure.) (Third edition.)

2272. **Storing electricity.** Swan. (Fifth edition.)

1889.

10933. **Electromoters.** Von Dolivo-Dobrowolsky and others. (Second edition.)

19555. **Electric induction.** Von Dolivo-Dobrowolsky and others. (Second edition.)

1890.

3082. **Incandescent electric lamps.** Langhans. (Second edition.)

5750. **Armatures for dynamo-electric machines, etc.** Crompton. (Fritsche.) (Second edition.)

8703. **Electric welding.** Thompson. (Coffin.) (Second edition.)

9861. **Electrical storage batteries.** Boult. (Tommasi and another.) (Second edition.)

14624. **Electrolytically making metallic articles.** Elmore. (Second edition.)

1893.

20698. **Electric cables.** Hardingham. (Felten and Guilleaume.)

21631. **Electrolytic apparatus.** Caldwell.

23074. **Electrical switches.** Theermann.

24889. **Phonographs, graphophones, etc.** Young.

24979. **Measuring and recording electric pressures and currents.** Baron Kelvin.

1894.

62. **Dynamo-electric machines.** Kingdon.

67. **Arc lamps.** Mensing.

646. **Voltaic batteries.** Walker and others.

14202. **Signalling by electric lamps.** Fitzpatrick. (Boughton Telephotos Company.)

15506. **Voltmeters, etc.** Brown.

17297. **Armatures for dynamo-electric machines.** Lake. (Eickemeyer.)

NOTES.

Lecture.—Mr. E. Scott, chief draughtsman to the Electric Construction Corporation, has delivered a lecture on "Electricity" at Wolverhampton.

Night Watchmen's Check.—An electric system for controlling the rounds of night watchmen is described, together with illustrations, in *L'Electricien* of December 1.

Old News.—The *Globe* has just discovered that the Allgemeine Elektricitäts-Gesselschaft (*sic*) have brought out an electrically-lighted lifebuoy. We gave particulars of this months ago.

City and South London Railway.—This Company have raised their fares between the hours of 8 and 10 a.m. to 3½d. from Stockwell to the City. There is a good deal of grumbling at this advance of ½d.

Smithfield Club Show.—This year the Smithfield Club Show will open at the Agricultural Hall on December 10 and will close on the 14th. In the machinery department the number of exhibitors is larger than ever.

Antwerp Exhibition.—The London Chamber of Commerce has received a copy of the official list of all the awards made to exhibitors at the Antwerp Exhibition. This list may be inspected at the office of the Chamber.

Bedford Electricity Works.—We omitted to mention in our description of these works last week that the photograph showing an internal view of the station was taken by Messrs. E. Walker and Co., of Midland-road, Bedford.

Look Here!—Lord Sandhurst, at a quarterly general court of the governors of Middlesex Hospital, stated that the adoption of the electric light in the hospital had effected a saving of several hundred pounds in the course of the year.

Lime-street Telephone Exchange.—The National Telephone Company announce that any subscriber to the system can obtain permission to view the new Lime-street exchange by applying to Mr. A. Calder, metropolitan manager, 58 and 59, London-wall, E.C.

Society of Arts.—On Monday next, at 8 p.m., the third Cantor lecture on "Modern Developments in Explosives," by Prof. Vivian B. Lewes, will be delivered. On Wednesday, at 8 p.m., a paper will be read on the "Manufacture of Salt," by Mr. Thomas Ward."

Electric Traction in Dublin.—One of the *Daily News* young men has evidently been reading some of the back numbers of the *Electrical Engineer*, for he announced on Monday that the Dublin Southern Tramways Company have made arrangements to run their cars by electricity.

Mining and Mechanical Engineers.—The North of England Institute of Mining and Mechanical Engineers assembles in general meeting to-morrow (Saturday) in the Wood Memorial Hall, Newcastle. Mr. Alex. Siemens will present a paper on "The Cost of Electric Transmission of Power."

An Opportunity for Electric Traction.—As will be seen from our report of the meeting of the Tramways Company of France, the company have decided to substitute electric for horse traction at Rouen. The opportunity is one which should not be overlooked by English electrical firms.

Madras Electric Tramway Company.—Mr. J. E. O'Shaughnessy, a retired senior executive engineer of the P. W. D., Madras, and lately executive engineer of the Civil and Military Station Municipality, Bangalore, has been appointed chief engineer to the Madras Electric Tramway Company.

American Institute of Electrical Engineers.—The offices of the American Institute of Electrical Engineers have been removed to Rooms 1,009 and 1,010, Havemeyer Building, 26, Cortlandt-street, New York. The institute meetings will be held at 12, West Thirty-first-street, as hitherto.

Cooking by Electricity.—*L'Energie Electrique* of the 1st inst., in paying a tribute to the efforts put forth in London to obtain a day load for supply companies by the use of electric heating and cooking appliances, refers to the apparatus made by Messrs. Crompton and Co., of which it gives various illustrations.

Royal Statistical Society.—A paper has been read before this society on "The Eleventh United States Census" by the Hon. Robert P. Porter, superintendent of the eleventh census. At the conclusion of the lecture, Dr. Holleritt, by means of lantern slides, gave an account of his system of electrical tabulation.

Finsbury Polytechnic.—The sixth annual dinner of the clubs and societies of this institution will be held on Saturday, 15th inst., at the Three Nuns Hotel, Aldgate. The Archdeacon of London will preside, and Mr. F. W. Pixley will be in the vice-chair. Tickets can be obtained of the hon. secretaries, at the institution, Appold-street, E.C.

Registered Telegraphic Addresses.—The third and last supplement to the 1894 volume of "Sell's Directory of Registered Telegraphic Addresses," containing new registrations, cancellations, and alterations from June 1 to August 31 in the case of the Metropolis, and for May 15 to August 11 in the case of the provinces, is about to be sent out.

Electric Light Lanterns.—A supplemental list for 1894-95 of electric light and other lanterns has been issued by Mr. J. H. Steward, of 406, Strand, and 7, Gracechurch-street, E.C. Among the various specialities mentioned in the list are an electric triple lantern, one for institution or club work, an electric theatre light in substitution for the limelight, and a scenic projection lantern, together with accessories.

Northern Society of Electrical Engineers.—The annual general meeting will be held at the Palatine Hotel, Hunt's Bank, Manchester, on Monday, December 10, when the president, vice-presidents, officers, and council for 1895 will be elected. A paper will be read "On the Commercial Possibilities of Accumulators for Tramcar Traction considered as a Municipal Undertaking," by Mr. A. H. Gibbings, member.

New Books.—We have received the following new books: "An Introduction to the Theory of Electricity, with Numerous Examples," by Mr. Linnæus Cumming, M.A., fourth edition, with corrections and additions, published by Messrs. Macmillan and Co., price 8s. 6d.; and "The Electro-Platers' Handbook: A Practical Manual for Amateurs and Young Students in Electro-Metallurgy," by Mr. J. E. Bonney, second edition, published by Messrs. Whittaker and Co., price 3s.

The Proposed Pacific Cable.—To those who are interested in the projected Pacific cable, an article published in the *Journal Télégraphique* of November 25 will be of interest. The article, which is accompanied by a coloured map showing the different routes proposed for the cable, summarises the progress of the scheme since 1893 and the position of affairs at the present time, not excluding an extract from the report presented by Mr. Alex. Siemens to the recent inter-colonial conference on the subject at Ottawa.

"Lightning."—Our contemporary has cut itself adrift from all respectable literature in its obvious lack of the commonest courtesies of life, and in its want of common decency, by indulging in personalities. We have no wish to graduate in the school of "Paul Pry" or *Town Talk*, and must therefore decline to enter the lists it so gracefully, in its own estimation, adorns. "There are critics who cannot swim, but who think it very clever to throw stones at swimmers." This sentence of Prof. Max. Muller might well be studied by many "knowing" people.

Institution of Civil Engineers.—On Tuesday next, at 8 p.m., an ordinary meeting will be held at which a paper will be read on "Colliery Surface Works" by Mr. Edw. B. Wain, A.M.I.C.E. On Friday next, at 8 p.m., at a students' meeting, a paper will be read on "Some Experiments on the Heat Losses to the Cylinder Walls of a Steam-engine" by Mr. S. Henry Barraclough, B.E., Stud.Inst.C.E., and Mr. Lionel S. Marks, B.Sc. Mr. Bryan Donkin, M.I.C.E., will take the chair.

Electric Traction in Egypt.—With reference to the note on this subject given in our issue of the 23rd ult., a telegram of Tuesday's date from Cairo states that the Cairo tramway concession to the Belgian Company was signed on that day. Lord Cromer has intimated to Mr. Fell that there is no chance of an amicable arrangement with the Egyptian Government, but the Government consents to acknowledge itself bound by Mr. Scott-Moncrieff's official letters as Under-Secretary. The hearing of Mr. Fell's case in the Appeal Court has been postponed.

Australian Cable Rates.—A Reuter's telegram from Wellington says: "The Victorian Government having announced its intention of withdrawing from the present inter-colonial arrangement regarding the cable subsidy, the Hon. J. G. Ward, the New Zealand Postmaster-General, has sent a reply to the Victorian authorities strongly deprecating the proposed withdrawal. He points out that it would compel the other colonies to follow Victoria's example, with the result that the high cable rates prevailing before the present agreement would be restored."

Transmission of Power.—The members of the Société des Ingénieurs Civils de France listened on the 16th ult. to a paper by M. G. Dumont dealing with investigations made by him, in conjunction with MM. G. Baignères and Lencauchez, on the electrical transmission of energy over long distances and on transmission by means of continuous currents. The paper, which was mainly of a historical nature, concluded by suggesting that electric transmission of power by means of overhead conductors should be preferably employed in organising the mechanical service of the exhibition to be held in Paris in 1900.

Removed from the Medical Register.—The General Medical Council on Saturday completed their enquiry into the conduct of Dr. Herbert Tibbits in connection with the "Medical Battery" Company and the establishment in Weymouth-street known as the "London Massage and Galvanic Hospital and West-end School of Massage and Electricity." The council decided to erase the name of Dr. Tibbits from the Medical Register. It is stated that erasure from the Medical Register carries with it inability to sue in a court of law for professional charges, or to sign valid medical certificates, and ineligibility for a number of public medical appointments.

New Mains in London.—The London County Council have sanctioned the laying of mains by the County of London and Brush Provincial Electric Lighting Company, under the County of London (North) Electric Lighting Order, 1892, in various streets in the northern and east central district; by the London Electric Supply Corporation in Blackfriars-road and Stamford-street, and in the Haymarket district; by the House-to-House Electric Light Supply Company in Old Brompton-road and neighbourhood; by the St. James's and Pall Mall Electric Light Company in King-street and Foubert's-place; and by the Westminster Electric Supply Corporation in Rochester-row and neighbourhood.

Institution of Electrical Engineers.—The annual general meeting will be held at 25, Great George-street, S.W., on Thursday next, the 13th inst. The annual report of the Council will be presented, and the election of Council and officers for the year 1895 will take place. Discussion will then be resumed on the following papers: "Electrical Steep-Grade Traction in Europe," by Mr. C. S. du Riche Preller, M.A., Ph.D., member; "Notes on Electric Tramways in the United States and Canada," by Mr. H. D. Wilkinson, member; and on "Electric Traction, with Special Reference to the Installation of Elevated Conductors," by Messrs. R. W. Blackwell, foreign member, and Philip Dawson, associate.

Electric Traction in Donegal.—Writing to the *Pall Mall Gazette*, "W. D. R." refers to an article published in that paper concerning the suggested construction of piers and harbours in county Donegal in preference to an expensive railway. He states that "if a railway be attempted I have often thought when glancing at the map, and when driving round the coast, that an electric carway (the electricity being generated by means of turbines on the innumerable streams) running along the coast road, would be the cheapest, both as to outlay and cost of working. It is, at any rate, a suggestion which should receive the attention of the Postmaster-General, as postal arrangements here are primitive in the extreme."

Applications for Provisional Orders.—In addition to the applications for electric lighting provisional orders to be made in the coming session of Parliament noted in our last issue, the following are announced: by the British Insulated Wire Company, Limited, of Prescot, to supply current in the townships and parishes of Prescot, Huyton, and Roby, Rainhill, Eccleston, and Whiston, all in the county of Lancaster; by the Municipal Electric Light and Power Corporation, 33, Old Broad-street, E.C., within the borough of Margate; by the Holloway Electricity Supply Company, Limited, 34, Victoria-street, Westminster, within the township of Great Crosby, Lancashire; and in Scotland for Montrose, Brechin, Motherwell, and Stirling.

Ealing Electricity Works.—The *Electrotechnische Zeitschrift*, in describing, in its issue of November 29, the electricity works at Ealing, assumes that the hot gases from the refuse destructor and fume cremator are only used for raising steam in the boiler or boilers for dealing with the day load, and that at night the gases are passed direct into the chimney, and the boilers fired with coal in the usual way. Whilst this course may be followed if desired, a reference to our description of the Ealing station will show that the works have been designed and have been operated so that one or two boilers may be fired with coal, and steam raised in the third by means of the hot gases, both operations proceeding simultaneously.

Ventilation of Conduits.—The recent explosions of gas and air in connection with junction-boxes, etc., of underground mains point very forcibly to the necessity for some effectual means of keeping gas out of the conduits, pipes, and boxes. One method which suggests itself is that of ventilation, but it seems doubtful whether pipes arranged in connection with the boxes will answer

Digitized by Google

the purpose. A far preferable precaution, and one which, we believe, has already met with success, is to put down a blower or blowers and force *dry* air through the conduits. This system has been adopted with satisfactory results at Newcastle and Cambridge, and it is intended to introduce the method at the Bedford central station, which we described last week.

A Funny Man.—Alderman Pollack, in moving the adoption of the report of the Birmingham Corporation Gas Committee on Tuesday, is reported to have said that he ventured to say that this light (*i.e.*, gas) was infinitely superior to the electric light, while its cost was hardly one-third, probably not one-fourth, of that of electricity. He trusted that the conductors of all large institutions, and especially of those fostered by the Council, would think twice before satisfying the craze of electric lighting, when they had at their command a light equally good, if not superior, supplied from their own works at one-fourth the cost. Judging from the amount of repetition in this short but erroneous passage, the alderman himself is fitted to be on the Gas Committee.

Wayleaves.—A dispute has arisen between the French Government and the Paris Municipal Council out of the purchase of the telephones by the State. The Government telephone department claim the right to put their conductors inside the sewers, and the Municipality want to charge for the wayleave. The Government refuse to pay, and they point to a law of 1885 which declares they can use the sewers for the purposes of public utility, to which argument the Municipality reply that in purchasing the telephones the Government have embarked upon a commercial undertaking, and that they cannot claim privileges in connection with it to which the commercial company they have supplanted were not entitled. The matter is to be decided in the law courts.

Electric Lighting in France.—A central electric light station has been put into operation at Arques-la-Bataille in an old mill, where the waterwheel has been replaced by a Hercules turbine. A Postel Vinay continuous current dynamo is employed, which supplies current at a pressure of 110 volts, the distribution being effected by two overhead conductors.—At Clisson Mr. Rauold, of Landerneau, is carrying out an electric station, the water power of the Sévre being utilised. Two Hercules turbines, each of 15 h.p., drive two Brown dynamos delivering current at a pressure of 125 volts. A 40-h.p. steam-engine will be added in the spring.—La Talaudière, a village of 3,000 inhabitants, in the Loire, has been furnished with a central electric light station.

English Ingenuity.—A compliment to the resources of English electrical engineering is paid by the *Elektrotechnische Zeitschrift* of the 29th ult. Our contemporary refers to the economical advantages arising from the use of accumulators in direct-current central stations for dealing with the day load, but the difficulty is to effectually meet this requirement in alternating-current stations. As instances of how this obstacle has been overcome in some English stations, it is mentioned (1) that at Bristol a small gas-engine alternator is laid down; (2) that at Worcester turbine-alternators are used; and (3) that at Ealing the hot gases from the refuse destructor suffice to deal with the day load. Thus English engineers may congratulate themselves on their ingenuity in endeavouring to economically provide for the day load.

Electric Organ-Blowing.—Electric motors have been introduced into St. Paul's Church, Prince's-park, Liverpool, for blowing the organ. Current is obtained from the mains of the electric supply company in Belvedere-road. At the left-hand side of the organ is a switch by which the organist not only starts or stops the electric motors, two in number, but by which he can regulate their speed to suit the requirements of the music he is playing. There is also an automatic regulating arrangement which controls the speed of the motors in accordance with the wind required. The motors are connected by means of belts and crank-shafts to the feeders, which supply the wind to the organ. The arrangement is very compact. The electrical engineers who have supplied and fixed the electric motors and gearing are Messrs. Bergtheil and Young, of London.

Gas-Engine Competition.—The question as to the relative efficiencies of different types of gas-engines is occupying the attention of French periodicals and makers of such motors. In this connection it is probable that some interesting experiments with gas-engines will be conducted at an exhibition of gas-motors which is being organised by a committee appointed by the Société Technique de l'Industrie du Gaz, of 65, Rue de Provence, Paris, on the occasion of the congress which is to take place in Paris next June. It has been decided in principle that the exhibition will be restricted to small motors of not exceeding 10 h.p., that each exhibitor shall only display one engine of each type made by him, that only coal-gas motors will be admitted, and that experiments may be made with the engines by a special engineering commission.

Berlin-Vienna Telephone.—The Vienna Press, says a Vienna correspondent, were invited on Thursday last week to speak over the new line of telephone to Berlin, which was to be opened for general use on Saturday. The result was surprisingly good on the Vienna side, but less so, it is stated, on the other. The length of the line is 660 kilometres, of which 430 are in Austria, so that it is much less extensive than the present line between Bodenbach and Trieste of 1,100 kilometres. The minimum charge is to be three marks for three minutes. The cost of the line is about £10,000. The Austrian engineers began simultaneously to lay the lines in Lower Austria and in Bohemia on September 9, and finished before the end of the same month. The line has now been officially opened by a conversation between the Emperors William and Francis Joseph.

Transformer-Chambers.—An enquiry is to be held at the Board of Trade on the 13th inst. into the subject of transformer-chambers. The London County Council and other local authorities in the Metropolis have objected to the chambers being placed in the public streets, contending that they are a serious obstruction in the roadway and may possibly interfere with the laying of gas, water, and other pipes in the future, and, further, that they are a grave public danger. They have therefore urged the Board of Trade to compel electric lighting companies to place their transformer-chambers on private property. On the other hand, those connected with the electric lighting industry contend that there is no danger to the public in placing the chambers in the streets, and that they can be so constructed as not to form any serious obstacle to the future use of the streets for other necessary purposes.

Steam-Pipe Covering.—According to *Power*, a certain test of steam-pipe coverings leads to the conclusion that it costs 15·40dol. to run 100ft. of naked 2in. pipe at from 70lb. to 80lb. pressure for one year of 3,000 working hours, with coal at 2dol. per ton. With the least efficient of insulating coverings used in the test this loss could be reduced to 4dol., with the most efficient to 2·64dol. Striking as are these figures, they are probably below the cost of actual practice, for a steam-pipe is under pressure usually more than 10 hours a day, and 2dol. a ton is below the average cost of coal. Prof. Charles B. Gibson, in some tests for

Digitized by Google

the Manufacturers' Mutual Insurance Company, some years since, reached the conclusion that with coal at 4dol. per ton and 3,000 working hours per year, the loss from a naked 2in. pipe was 64½ cents per linear foot—considerably more than Mr. Dickinson's test would show even with coal at 4dol. per ton. However, the lowest of the estimates shows the importance of covering the pipes.

African Telegraphy.—A Reuter's message from Blantyre (British Central Africa), dated October 16, says that great progress has lately been made with the construction of the telegraph line, and the most satisfactory co-operation has existed between the Portuguese and British authorities. Mr. Watson, the engineer employed by the African Transcontinental Company, has spanned the Zambesi at Tete, making use of an islet in the middle of the river for the support of the wire. The line has been completed between Blantyre and Tete, and also between Salisbury and Mazoe, 150 miles from Tete. A conference of agents-general and representatives in London of the South African Governments was held on Wednesday at the office of Sir Charles Mills, agent-general for the Cape of Good Hope. The countries represented were the Cape, Natal, Transvaal, Orange Free State, and several of the minor British possessions. The object of the discussion was to endeavour to obtain a reduction of the cable rates to the territories concerned.

Royal Institution.—The members of the Royal Institution held a monthly meeting on Monday, Sir James Crichton-Browne presiding. The following gentlemen were elected members: the Rev. J. O. Bevan, Messrs. H. T. Brown, F.R.S., H. S. Keating, G. Lindo, S. Morse, E. Steinkopff, G. J. Stoney, F.R.S., C. L. Tuckey, M.D., A. E. Western, C. Wightman, and G. W. Wolff, M.P. The special thanks of the members were returned to Mr. Ludwig Mond and Dr. William S. Playfair for donations towards the fund for the promotion of experimental research at low temperatures. Among the lecture arrangements announced were Prof. J. A. Fleming, F.R.S., six lectures, adapted to a juvenile auditory, on the "Work of an Electric Current," and the Right Hon. Lord Rayleigh, six lectures. The Friday evening meetings will commence on January 18, when Prof. Dewar will deliver a discourse on "Phosphorescence and Photographic Action at the Temperature of Boiling Liquid Air." Succeeding discourses will probably be given by, among others, Prof. A. Schuster, Prof. A. W. Rücker, Prof. Roberts-Austen, Prof. H. E. Armstrong, and the Right Hon. Lord Rayleigh.

Conduit Electric Tramways.—A paper asking the question as to whether there is a solution of the electric conduit railway problem was read recently by Mr. Joseph Sachs before the Electrical Society of New York. The author stated that the reasons for the non-success of such lines were that most of the projects were immature, that the inherent difficulties were great, and that the cost of construction was very large. On the other hand, he thought that the maintenance would seem to be less expensive than with the trolley. After describing a number of conduit systems, the author said that there was not much of a choice between them, as there had apparently been nothing practical evolved from the number described, except the plain open-slot conduit and continuous-wire system. This was the one in actual operation, and it had given satisfaction both at Budapest and at Blackpool, but he considered it was doubtful whether it could be made practicable in the United States, where the climatic and local conditions were different. The author was of opinion that we shall never get a conduit system which could be put in for £4,000 a mile, single track, and that it might be as high as £6,000 or £8,000 per mile single track. The system which is to be installed upon Lenox-avenue by the Metropolitan Traction Company was then described.

Luminescent Electric Lights.—Mr. H. Ebert recently contributed a paper of great interest to Wiedemann's *Annalen* on the production of light by high-frequency currents, in which results are indicated which are likely to prove of the utmost importance. The fundamental difference between the light and that associated with Tesla's name seems to be in an insistance upon the principle of resonance. He says that it is not necessary to use high tensions, since it has been found that intense light effects can be produced by the movement of exceedingly small quantities of electricity, provided only that the oscillations follow each other regularly and are persistent. The luminous substance of Ebert's "luminescent" lamp is said to be a small disc of compressed luminous paint. This is enclosed in an exhausted glass receiver, upon the external surface of which are glued two strips of tin-foil, to which the terminals of the circuit are attached. When the electric oscillations act upon these coatings active cathode rays are formed on the inner surface. These, though almost invisible themselves, produce a strong luminescent light upon the surface of the luminous paint. To determine the efficiency of the lamp, it was compared with the amyl acetate standard. Its candle-power was found to be about one-thirtieth of this, which is approximately equal to the standard candle. It was found that the energy actually expended in producing this light was only about one-millionth of a watt.

Government Telegraphy.—According to the *Daily Telegraph*, a proposal is under consideration at St. Martin's-le-Grand to celebrate in some becoming way the silver wedding of the State and the electric telegraph. "That union was effected on February 5, 1870, and the parties will therefore have reached the twenty-fifth year of a prosperous and profitable wedded life on February 5 next year. The occasion is one which merits to be marked with some festivity, for it signalises a date when stock can be taken of the immense progress made in the speedy transmission of messages nationally and internationally in 25 years. When the State took over the telegraphs, electricity as a means of communication was in its infancy. It has now reached a stage of considerable development, and promises in the future to attain a stature which no man may measure. Those who have never had the privilege of viewing the immense department of telegraphs at St. Martin's-le-Grand—a department which is continually increasing—can hardly imagine the extent to which the telegraph is now used, and the varied machinery, much of it of the most exquisite delicacy, placed at the service of the public. Many of the improvements made in the transmission and reception of messages have been the patient work of Post Office electricians, who freely put their discoveries at the disposal of the Government and the community without patent or reservation. It may safely be said that no country in the world has been better served telegraphically than this, and in none have greater developments been made quietly and unostentatiously. Under such circumstances, the silver wedding of the telegraphs and the State is worthy of cordial and hearty celebration."

The Light Railways Conference.—The following bodies were represented at the conference on light railways held yesterday at 8, Richmond-terrace, Whitehall:—London County Council: Rev. Fleming Williams, Mr. Bruce, Mr. Beachcroft. Association of Chambers of Commerce: Sir Albert Rollit, M.P., Sir Bernhard Samuelson, M.P., Sir Alfred Hickman, M.P., Mr. F. Corbett. Central

Digitized by Google

and Associated Chambers of Agriculture: Mr. Channing, M.P., Mr. Jeffreys, M.P., Mr. R. H. Rew. London Chamber of Commerce: Sir Edward Carbutt, Mr. E. Garcke. Railway Companies' Association: Lord Claud Hamilton, Mr. J. C. Bolton, Mr. W. L. Jackson, M.P. Institute of Civil Engineers: Sir Benjamin Baker, K.C.M.G., Sir Douglas Fox. Association of Municipal Corporations: Mr. Alderman Brownsword, Mr. Harcourt Clare, Mr. G. C. Kent. Association of County Councils: Sir John Hibbert, K.C.B., M.P., Lord Thring, Lord Edmond Fitzmaurice, Mr. Henry Hobhouse, M.P. Scottish Chamber of Agriculture: Mr. Alexander Cross, M.P. Surveyors' Institution: Mr. E. P. Squarey, Mr. C. Oakley. Tramways Institute of Great Britain and Ireland: Mr. Carruthers Wain. Mansion House Association on Railway and Canal Traffic: Sir James Whitehead, Mr. Tomlinson, M.P. Institution of Electrical Engineers: Mr. Alexander Siemens, Major-General Webber, C.B. Royal Agricultural Society of England: Earl Cathcart, Mr. W. Frankish, Mr. Ernest Clarke. National Traction Engine Owners' and Users' Association: Mr. R. W. Eddison. British Dairy Farmers' Association. In addition, certain gentlemen having expert knowledge of the subject-matter attended the conference, among whom were the following: Duke of Sutherland, Lord Farrer, Lord Kelvin, Sir Juland Danvers, Sir Alexander Rendel, Mr. W. M. Ackworth, and Sir Richard Sankey.

Three Tracks.—Lately our American namesake wrote on the subject of the use of electric traction on short lines of English railway such as the City and South London, and it has now received the following rather curious suggestion from a gentleman who is described as a well-known steam railway expert, who writes: "It does not seem to me possible that one set of rails can answer both conditions—*i.e.*, keep the rails incessantly occupied with trains of the greatest possible frequency—say, with single cars or two cars running without schedule—and at the same time get high speeds. This query does, in fact, go to the root of the subject, but it seems to us that the answer lies in the resort to a third track. The New York Elevated has used this method for some time, and would use it even more if it were not to somebody's advantage to prevent it. By its means, even on its present limited scale, the Elevated can and does run its express trains down in the morning and back at night at high speeds, and with results most satisfactory to the passengers; while the two outer tracks are occupied by slow-moving trains either way. Now the conditions are very much the same on a large proportion of the English steam roads around the great cities, with several tracks extending for miles out; and we do not see any real difficulty in adjusting the bulk of the express traffic to a third track construction, thus giving a ceaseless service on the outer tracks either way and at a very high speed one way at certain hours of the day. The third track would also be available for no small amount of freight traffic in the hours when no expresses were moving. In this way it seems to us a greater traffic plying incessantly at remunerative low fares, approximating street-car fares, can be got upon part of the system, while it will be possible to run the expresses at higher speed than ever."

Electric Traction in Germany.—Two new electric traction schemes are announced in Upper Silesia. One of these is for a line from Antonienhütte to Morgenroth, Godullahütte, Schomberg, and Beuthen. The second, which is projected by Messrs. Schuckert, is to connect Königshütte, Heiduk, Schwientochlowitz, Zalenze, Kattowitz, Zawodzie, Bogutschütz, Dombrowka, Laurahütte, Rosdzin, and Schoppinitz. — Mr. Lehfeldt, of Leipsic, agent for the Allgemeine Elektricitäts-Gesellschaft, is projecting an electric tramway for Bamberg.—It is intended to construct an electric tramway to connect Cassel with Wilhelmshöhe.—A syndicate has been formed to erect a central electricity station and an electric tramway in Zwickau.—The line of steam tramways from Frankfort-on-the-Maine to Eschersheim has been acquired by the Union Elektricitäts-Gesellschaft, of Berlin. They will convert it into an electric line and propose to extend it to Oberursel.—Mr. Bachstein, a light railway contractor, has prepared a scheme for an electric tramway up the Wartburg, a matter which has been discussed for a long time. The line will pass through the streets of Eisenach.—The Munich local authorities have given permission for electric traction to be introduced on the tramway line from Färbergraben to Isarthal railway station. The tramway company will obtain plant and 12 motor cars from the Union Elektricitäts-Gesellschaft, and two reserve motor cars from Messrs. Schuckert and Co.—Mr. Otto Lohausen is seeking for a 45 years' concession for four electric lines in Berlin.—The overhead trolley electric tramway which has been constructed in Plauen by the Allgemeine Elektricitäts-Gesellschaft, is now in operation. It runs through the centre of the town and establishes communication between the two railway stations, which lie at opposite sides of the town.—A project for an extension of the Dresden electric tramway from Laubegast to Kleinschachwitz has been laid before the Minister of the Interior. A proposal is on foot to convert the Duisburg-Ruhrort horse tramways into an electric line.

Municipal Electric Lighting.—In the course of a paper read on this subject before the Canadian Electrical Association by Mr. E. Carl Breithaupt, of Berlin, Ontario, he said, after suggestions as to possible corrupt practices, that "there are other additional arguments against municipal ownership of lighting plants. The function of a Government is to regulate and control and to encourage enterprise on the part of its citizens by extending a protecting hand over the industries they establish. When a number of citizens band together, therefore, to carry on a business which is at best an uncertain one, one in which their works and plant are liable to serious injury from various causes, and in which they are not free to trade where and with whom they choose, but are restricted to localities—a business which confers a benefit to the community, and which is already more or less subject to municipal and legislative control, then it is obviously unjust for the municipality to establish and operate a plant in opposition to that of the private company. If a municipal corporation decide to enter into a field of commercial enterprise in which some of its citizens are already engaged, it is only simple justice that it shall offer to take over their works and plant at a fair and equitable price. Again, the wisdom of a municipality engaging in a commercial enterprise may be questioned; indeed, it is a grave question whether the Corporation has the moral right to risk the money of its citizens in an undertaking which is attended with such hazards, and in which the advantages to be gained are in any event small and uncertain. Many cities and towns have been persuaded by incomplete reports and alluring estimates to undertake the experiment, but it still remains to be proven that a municipal plant can supply a cheaper light than a private company. In towns which are not large enough to make the business remunerative, the installation of a plant by the corporation may be justified, because street-lighting is a public necessity; but where private plants already exist that are able and willing to supply the municipality at a fair price, the outlay cannot be regarded otherwise than as an unnecessary expenditure and a waste of public money."

PHYSICAL UNITS.

BY MAGNUS MACLEAN, M.A., F.R.S.E.

(All Rights Reserved.)

(Continued from page 642.)

PRACTICAL ELECTRIC UNITS.

§ 66. Let a conducting circuit be placed in a magnetic field, and let the current in this circuit be Γ under the action of an electromotive force E. Let the circuit be so moved that in time t the number of lines of force passing through it is increased by N, then the work contributed by the electromagnetic forces is measured by the product Γ N. But the work done on the current is E Γt.

$$\therefore E\Gamma t + \Gamma N = 0;$$

$$\therefore E = -\frac{N}{t}.$$

Hence, if the number of lines of force enclosed by a circuit be increased, an E.M.F. in the negative direction is set up, and the measure of this E.M.F. is the number of lines of force added per unit of time.

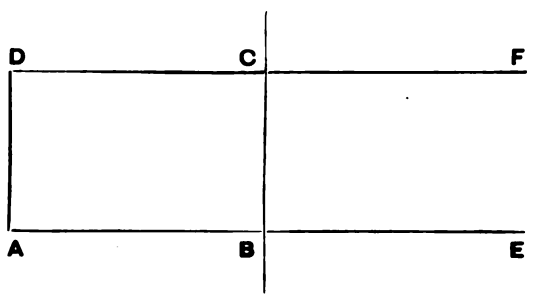

FIG. 3.

§ 67. In Fig. 3, let the circuit consist of two long parallel metallic rails A E, D F, connected permanently by a wire A D. Let B C be a slider free to move along the rails either towards A D, or E F. Suppose the plane of A B C D to be vertical, the rails to run from west to east, and that you are looking northwards at the figure, then the direction of the lines of force due to the horizontal component of the earth's magnetism is from the front of the page to the back, and these lines are practically parallel to one another. If a current in the circuit is in the direction A D C B, the slider will move eastwards towards E F, and cause an E.M.F. of the magnitude H l v to act round the circuit in the direction A B C D, where H is the number of lines of force per unit area perpendicular to A B C D, l is the length of the slider B C, and v is the velocity it has in the eastward direction. This illustrates the direction of the resulting E.M.F. Now if there be no current in the circuit, if the magnetic field be unity (one line of force per square centimetre), and if the distance between the rails be one centimetre, unit E.M.F. is induced in the circuit when the velocity of the rail is one centimetre per second. Thus unit E.M.F. is produced in any body which moves so that it cuts one line of magnetic force per second.

This unit is found to be too small for practical purposes, and a unit one hundred million times greater, called the *volt*, is taken as the practical unit. Thus, if we still suppose the rails to be one centimetre apart, and to be placed at right angles to a magnetic field of force of unit intensity, then when the slider moved with a velocity of one hundred million centimetres per second, the E.M.F. produced in the circuit would be one volt.

An E.M.F of one volt = 10^8 C.G.S. units.

§ 68. It is seen from § 59 that the dimension of resistance is a velocity, and Fig. 3 will, as first suggested by Lord Kelvin, show how a velocity may express a resistance. Instead of the linear conductor A D joining the ends of the rails, let us have a coil of vertical wire of radius r, with its plane in the magnetic meridian and a short magnet suspended at its centre. Let this magnet be deflected to an angle θ, when the uniform velocity of the slider towards E F is v units of length per unit time. Then if R be the resistance of the slider and circle of wire (the resistance of the rails being so small as to be negligible in comparison, so that the resistance of the whole circuit before the slider begins to move is R, and is still R after it has moved for some time) the current, by § 55, is

$$\Gamma = \frac{r}{2\pi} \cdot H \tan\theta.$$

But by the preceding section $\Gamma = \frac{H l v}{R}$;

$$\therefore R = \frac{2\pi l v}{r \tan\theta}.$$

If the radius of the coil be equal in length to the circumference of a circle whose radius is the distance between the rails, and if θ is 45deg., then R = v. Hence the resistance of the circuit in electromagnetic units is the velocity with which the slider of length l must move so as to give a deflection of 45deg. to the magnetic needle suspended at the centre of the coil. Note that this velocity is independent of the moment of the suspended magnet, and of the intensity of the field. It is also independent, as was pointed out by Weber, of the fundamental unit of length and of time chosen. In the centimetre-gramme-second system of units, unit velocity is a centimetre per second, hence unit resistance on this system is a centimetre per second. But for practical purposes this unit is too small, and a unit one thousand million times greater is taken as the unit of resistance, and is called an *ohm*.

A resistance of one ohm = 10^9 C.G.S. units.

§ 69. The practical unit of current derived by Ohm's law from these practical units of E.M.F. and resistance is called an *ampere*.

A current of one ampere = $10^8 \div 10^9$ C.G.S. units
= 10^{-1} C.G.S. unit.

70. The quantity of electricity conveyed by an ampere in one second is called a *coulomb*. An ampere is a coulomb per second.

A quantity of one coulomb = 10^{-1} C.G.S. unit.

§ 71. The practical unit of capacity is called the "farad," and by § 44 a condenser has unit capacity when a charge of one coulomb raises it to an E.M.F. of one volt.

A capacity of one farad = $10^{-1} \div 10^8$ C.G.S. units
= 10^{-9} C.G.S. units.

§ 72. The work done in raising a quantity of electricity Q, through a difference of potential E, is equal to the product of these two quantities. Hence

$$W = EQ = E\Gamma t = \Gamma^2 R t = E^2 t / R.$$

If these quantities are expressed in the absolute electromagnetic centimetre-gramme-second system of units, the work done in any time t is expressed in centimetre dynes or ergs. If they are expressed in terms of the practical units (for example, E in volts and Q in coulombs)

$$W = E \times 10^8 \times Q \times 10^{-1} = EQ \times 10^7 \text{ ergs.}$$

The work done by raising a coulomb of electricity through a difference of potential of one volt, is, on the suggestion of Sir William Siemens, called a *joule*.

One joule of work = 10^7 ergs.

Thus, if the difference of potential be expressed in volts, the current in amperes, and the resistance in ohms, the work done in any time t in an electric circuit is

$$W = E\Gamma t \text{ joules.}$$
$$= \Gamma^2 R t \quad ,,$$
$$= E^2 t/R \quad ,,$$

§ 73. If a joule of work be done in the circuit during each successive second of time, and if the work be done uniformly, then the rate of doing work is called a watt.

One watt = one joule per second
= 10^7 ergs per second.

Hence, expressing E in volts, Γ in amperes, and R in ohms, the activity in an electric circuit is

$$A = E\Gamma \text{ watts}$$
$$= \Gamma^2 R \quad ,,$$
$$= E^2/R \quad ,,$$

Digitized by Google

To reduce this activity to horse-power, we have to divide by 746, for 1 h.p. = 550 foot-pounds per second

$$= 746 \times 10^7 \text{ ergs per second}$$
$$= 746 \text{ watts (see § 26)}$$

One kilowatt = 1,000 watts $\doteqdot 1\frac{1}{3}$ h.p.

The Board of Trade supply unit is one kilowatt for one hour, or a kilowatt-hour. It is, therefore, equal to 3,600 × 1,000 joules

$$= 3{\cdot}6 \times 10^6 \text{ joules.}$$

This is a departure from the decimal system, and many people specially wedded to the decimal notation state that the Board of Trade might have chosen* a million joules as the unit, and that wattmeters and joule-meters could have been graduated to such a unit quite as readily.

The practical unit of induction is called a *quadrant*, and is taken as 10^9 centimetres.

§ 74. The following table gives the ratio of these practical units to the units both in the electrostatic and electromagnetic systems:

—	Name.	Symbol.	Value in Electrostatic units.	Value in Electromagnetic units.
Quantity of electricity.	Coulomb	q Q	3×10^9	10^{-1}
Current ...	Ampere	γ Γ	3×10^9	10^{-1}
Potential difference..	Volt	e E	1/300	10^8
Resistance..	Ohm	r R	$1/9 \times 10^{11}$	10^9
Capacity.	Farad	c C	9×10^{11}	10^{-9}
	Microfarad		9×10^5	10^{-15}

§ 75. As these ratios are of great importance in the reduction of experimental results, they are given directly in terms of one another as follows:

One ampere $= 3 \times 10^9$ electrostatic units of current.

$= \frac{1}{10}$ electromagnetic unit of current.

One volt $= \frac{1}{300}$ electrostatic unit of potential.

$= 10^8$ electromagnetic units of potential.

One ohm $= \frac{1}{9 \times 10^{11}}$ electrostatic unit of resistance.

$= 10^9$ electromagnetic units of resistance.

One microfarad $= 9 \times 10^5$ electrostatic units of capacity.

$= \frac{1}{10^{15}}$ electromagnetic unit of capacity.

WHAT IS GRAVITY?

BY R. C. SHETTLE, M.D.

I think that the nature of this important form of energy is capable of being readily explained, provided we start our investigations with the conception of space as occupied by a medium the component elements of which are physically and mathematically identical in character.

It appears logically certain that such a medium must exist in one of two states—either it must take the form of a solid or of a perfectly homogeneous stuff. And as we know that the condition of the universe does not admit of the former, we are compelled to accept the latter conclusion, and to imagine space as having been occupied by stuff in a perfectly homogeneous state—in fact, by a medium in which the amount of stuff and of existent energy was disseminated with mathematical equality throughout.

It is evident that in such a medium, apart from any impressed force, there must be a state of *complete rest*, because without differentiation there could be no motion existent from within. And as we further recognise that gravity is essentially a force by which one body attracts another in proportion to the mass and inversely with regard to the square of the distance, we perceive that the energy of the stuff in which one uniform degree of density existed throughout, would tend to maintain equality of distribution and complete rest by the same laws which regulate gravity under any greater conditions of the force, because every portion of the stuff could only attract to the same extent as it was itself attracted by every other portion of the stuff with which it was in contact.

But the converse necessarily applies also, for the *energy* existent in any portion of the stuff became a *source of motion* as soon as balance of power had been disturbed by differentiation of density under *impressed force*. Therefore when motion had been originated, and matter had been formed by condensation, the sources of motion became infinite.

But it is obvious, to effect this change from a state of perfect rest to a state of incessant motion, the force must have been impressed in such a manner that *order*, and not disorder, should have resulted—*i.e.*, the consequent mechanism must have taken such form that the work done should originate the least possible degree of friction. Astronomy reveals the fact that, with few exceptions, the various bodies which constitute the universe are undergoing a special form of axial rotation, the general direction of which is the same.

The present paper attempts to define the mode in which the present condition of the universe would have been effected by the definite application of *power* to such a medium as I have described.

I will illustrate the principle to which I have referred in the following way: A number of magnets suspended in the same plane after a definite time come to rest, the general position of the magnets being the effect of the whole number, modified somewhat by the force of terrestrial magnetism. If now the position of one of the magnets be changed, the whole of the others under the influence of the general forces move also. Logically we may assume that very similar phenomena would have resulted if motion had been imparted to the homogeneous stuff which I have described.

I will now attempt to point out the very simple mode in which the general principles which I have defined appear to me to have brought the material universe into existence. The following are the points upon which I base my hypothesis of the formation of the universe under the influence of gravitation.

I.—That prior to the existence of formed matter space was occupied by a dense description of equally diffused and undifferentiated stuff, and that this stuff, owing to the perfect equilibrium which necessarily prevailed, was in a state of complete rest and devoid of any power of originating motion.

II.—That power was applied, and motion originated thereby.

III.—That the immediate effect of the motion was differentiation of mass quantity—by the condensation of some and the attenuation of other portions of the stuff.

IV.—That the secondary effect of motion was atomic cohesion; this was followed by molecular cohesion, and then by the aggregation of the larger masses under the weaker manifestation of the same force, now known as gravity.

Lord Kelvin has shown that "under certain conditions there will be produced by *pure* gravitation a force of attraction which may be of any amount however great." These conditions appear to me to be fulfilled in the perfectly homogeneous state of the primary stuff. Thus this stuff may be defined as highly elastic, the elasticity depending upon the *absolute contact* of its component parts, all of which having an equal density would equally attract and thus tend to maintain equal diffusion.

It is therefore logical to assume that any differentiation of the density of the stuff must result in a tendency of the denser portions to become more dense, partly because the parts of the stuff have been approximated under a force, the intensity of which, by the laws of gravity, must increase the more closely the parts are associated, and partly

* By the same reasoning, the earth might have made a hundred or a thousand rotations on its axis while making one complete revolution round the sun.

Digitized by Google

because in proportion to the attenuation the energy of the surrounding medium has been locally diminished. In fact, the energy of the condensed portions would act from the circumference towards the centre. Now, as the extent of this attraction has been shown to be illimitable, the degree of compression or condensation which is capable of being exercised by absolute contact of the parts of the forming bodies would be regulated more especially by the quantity of the stuff differentiated; a point which appears to signify that the degree of density in matter is largely determined by the quantity of stuff which was apportioned to each form of matter.

V. I further venture to think that this atomic cohesion and all other forms of gravity are due to the attraction which bodies mutually exercise to *relieve pressure, regain equilibrium, and equal diffusion*, through the stress of other matter. Indeed, various natural phenomena when closely examined upon the principle embodied in this hypothesis clearly, as I think, indicate this. Thus this hypothesis shows that condensation is only a phase of a general elasticity resulting from inequality of diffusion of the original stuff, and it seems only logical to conclude that the formed thing should revert to the unformed—*i.e.*, to its original state—provided the conditions by which it was formed were removed; indeed, we know that the falling together of the celestial bodies would result in the dissociation by heat of their elements, and they would become stuff once more.

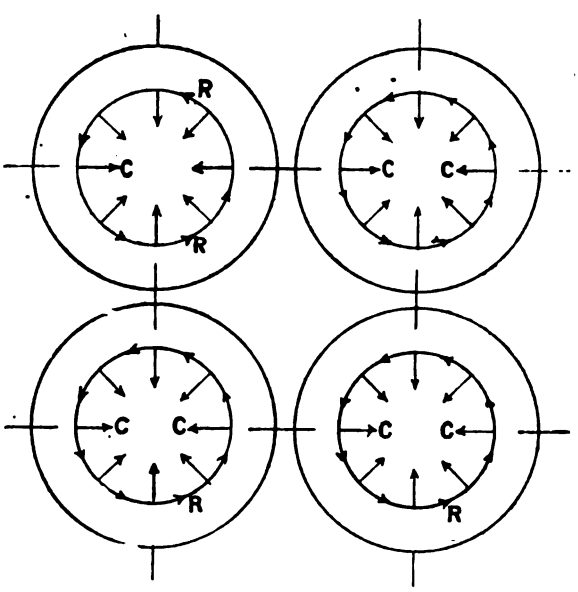

Diagram No. 1.

I append two diagrams illustrative of this point. No. 1 shows the mode in which differentiation of the stuff and the definite axial rotation of the condensed portions is supposed to have brought the material universe into existence. Under these conditions the stuff is being converted into a solid state whilst it is undergoing a definite form of axial rotation, the same general conditions resulting in the aggregation of the atoms into molecules, and subsequently into, it may be, the largest masses of the universe

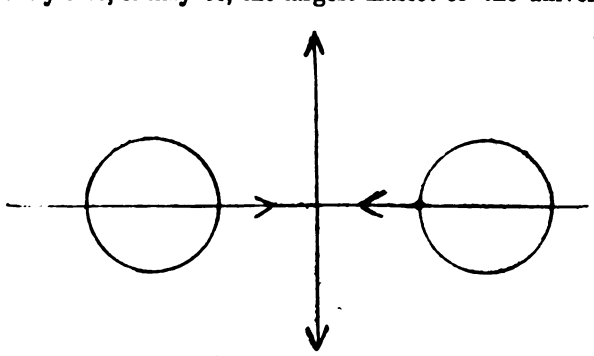

Diagram No. 2.

(in accordance with the theory of Laplace), whilst all the component elements are subject to the same description of axial rotation, performed with infinite precision. No. 2 shows the mode in which formed matter is reconverted into the original homogeneous stuff by throwing the mechanism out of gear and causing the masses to collide. In the latter state the new motion is productive of disruption, and as a consequence with proportional dissipation of matter.

VI. It is only logical to conceive that if the units of the masses were formed under *rotation* of the stuff, the centres which are undergoing condensation and conversion into formed matter would leave interspaces upon which no such condensation was exercised; but, on the contrary, the stuff in these spaces would become very highly attentuated by the dragging influence which each atom during its formation by condensation would exercise upon it. This hypothesis supposes that this residuum constitutes the *ether*, which is now supposed to pervade all matter and space. Thus, I define ether as the residuum of the primary stuff, and I think it logical to assume that just as a special quantity of stuff seems to have been necessary for the production of each form of matter, so a special quantity of the stuff was left to form a fitting medium, the ether, for the manifestation of the phenomena characteristic of the various forms of material energy. I may go further and say that it appears to me that a definite degree of tenuity would be effected, provided the stuff in the interspaces were subjected to attenuation, because the quantity of the stuff in these areas (marked S in the diagram) would always be determined by the areas in which the stuff was undergoing condensation. Upon this principle we perceive that the stress which bodies exercise upon the ether imparts great rigidity in the line of stress. I may add that I believe the ether which is condensed upon the atomic surfaces has an important function to perform in relation to animal and vegetable life. I think that Diagram No. 1, showing as it does the conversion of the stuff into a solid under rotation, necessarily conveys the idea of polar compression. I therefore assume that the formation of the atoms was attended with what may be described as double vortical motion of the homogeneous stuff.

VII. My next point is to show the mode in which the ethereal matter now pervades the larger masses of the universe with the same description of motion, either actual or relative. To define the character of these vortices as they are supposed to exist in a mass of formed matter, such as the earth, it is necessary to consider the facts closely upon which the hypothesis is based. In doing this we recognise that we have to deal with a porous mass of matter travelling through space with a high velocity. The axial rotation has a velocity of 500 *yards* a second. The orbital motion a velocity of 19 *miles* a second. The proper motion of the earth towards Hercules, as a unit of the solar system, is supposed to have a velocity of *four miles* a second. With reference to the effects of these motions of the formed matter upon the ether with which they are associated, we recognise (1) that the masses are highly porous; (2) that the ether pervades the atomic and molecular interspaces; (3) that each atom of formed matter in proportion to its mass appears to be acting as an exhaust engine upon the ether; (4) that as the ether is the residue of the stuff from which the atoms have been formed by condensation, it is necessarily very dense and closely packed upon the atomic surfaces. Consequently, every mass of gross matter is equally a reservoir of ethereal matter. This ethereal matter may be said to exist in at least three states: (*a*) that in which its density is greatest on the surface of the atoms; (*b*) that in which the density has been considerably reduced in the molecular interspaces; and (*c*) that of its highest state of rarefaction when it exists between the largest masses of the universe.

Accordingly, I think it logical to assume that in the first state it must (as Fresnel supposes) partake of the motions of the atoms. In the second, its velocity must be diminished in inverse proportion as the distance from the atom has increased, and, therefore, that it has a relative motion in the opposite direction. Whilst in the third state it has little or no motion of translation, but a relative motion opposite in direction to the motion of the masses, the velocity of which must be in proportion to their rate of motion—*i.e.*, as the stress upon the ether *takes its origin in the mass and partakes of its character and motion*, the intensity of stress upon the ether must diminish very rapidly as the

Digitized by Google

distance from the atoms increases. It seems, indeed, certain that the ether has *a form, a character, and a motion*, which is the counterpart of that of the matter.

I therefore arrive at the conclusion that the earth, or any similar mass of matter, according to the stress which it exercises upon the stuff, throws it into vortical motion, the velocity and relative direction of which motion to the matter must be determined by the degree of stress.

I will now endeavour to point out the effect which two opposite bodies, such as the sun and the earth, mutually exercise by stress upon the ether contained in their respective masses, and with which they are otherwise associated. It is evident that the greatest intensity of stress existing between any two bodies is situated at points upon the surface of each, which may be defined by a straight line drawn through the centre of each. From thence stress is distributed in parallel lines in every direction in proportion to the mass. Thus, let A B represent two such bodies, and the line C A B D the line of the greatest intensity of stress.

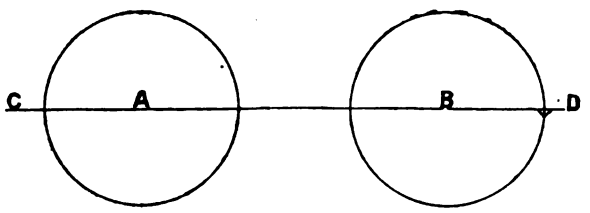

Diagram No. 3.

The effect of these stresses thus far is seen to be identical with those of gravity, but it is very important to bear in mind that whilst the formed matter traverses space as a highly porous body, the ether, except on the atomic surfaces (on which it is condensed, and to which it is therefore attached) is an immeasurably attenuated stuff which passes freely through those pores, and that it is at all times subject to stress.

It will also be recognised that A B, as parts of a system, are rotating axially in the direction shown by the arrows, and at the same time are traversing space in the direction and with the velocities already defined. With regard to the earth, we know that the resultant of the combined motions is *helical*, because it is compounded of a movable inclined plane and a lever—*i.e.*, the motion is the resultant of its axial, orbital, and proper motions. Consequently we find—

I. That each mass in proportion to its density is tending to drag the matter and the ether of the opposite mass towards itself; but whilst the formed matter under gravity pursues its well-defined motion, the ether, subject to the conditions named, is rushing through the molecular interspaces with a velocity which is in proportion to the motion of the mass, and a direction which is determined partly by the direction of the mass motion (to which it mostly has a relative motion in the opposite direction) and partly by the stress of the opposite body.

II. That in consequence of the helical motion of the masses the ether which traverses them partakes largely of the same description of motion, and as the point upon the surface of each mass where the intensity of any *external* stress is most marked is incessantly and very rapidly changing, so also are the conditions of the ether with regard to stress, and I think the only logical conclusion is that the ether is constantly being dragged by the stress through and out of the mass, the point of the greatest stress being the point where the ether makes its main exit, whilst the points which appear to most favour its entry are situated at or near the poles of rotation, thus giving origin to ethereal currents on the surface of the earth, something like the distribution of air currents from the poles to the equator, only reaching to a far greater extent.

III. That, as a consequence, the ether as it passes through a mass under the influence of external stress tends to assume double vortical motion, one of these vortices having a right and the other a left hand direction, the bases of the vortices being situated at and about the poles, and the apices at the point on the line of the ecliptic which marks the greatest intensity of stress.

IV. It is evident that none of these phenomena could be originated upon distant bodies, unless each mass by its own motion and stress originated motion in the ether with which it is associated. This also necessarily partakes of helical motion, and two vortices are formed thereby, the bases of which are situated at the line of the ecliptic, and the apices at the north and south pole. It will be observed that the bases of these vortices are situated at or near the line of the ecliptic, and the apices at or near the terrestrial poles. But in the case of the vortices which result from the action of distant bodies (as I have already stated), the bases of the vortices should be at or near the poles, and the apices where the intensity of stress is most marked on the line o the ecliptic.

V. That as each *external stress* is productive of similar effects, there exists a double vortex motion of the ether for each external stress; but the position of each pair of ethereal vortices varies with the relative position, which the bodies creating stress assume at any given moment.

VI. A necessary result of this stress upon the etherea matter is action and reaction throughout the entire mass, a process which essentially tends to keep the atoms and the mass compressed whilst undergoing axial rotation because each atom of the mass, or the mass itself, engaged in the production of stress is dragging the ether in two opposite directions at the same time, with stress which is proportional to the matter engaged in its production.

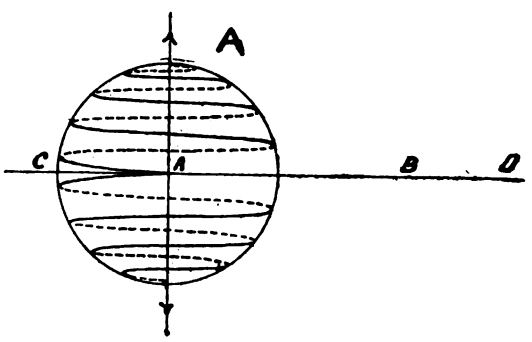

Diagram A.

The diagram marked A shows the stress of the sun producing a right and left hand helix of ethereal stuff in the earth. The central line marks the seat of the greatest intensity of stress, but the same description of stress exists, of course, all over the earth's sunward surface. There is, however, a more perfect mode of illustrating this phenomenon by the influence of magnetic stress upon iron filings. It is an experiment which I conducted many years since, and may be repeated in the following manner: Place some iron filings in a glass cell about 6in. long and 6in. wide, the interior of the cell being about ¼in. across, so as to prevent the poles of the magnet being too widely separated, then place it between the poles of an electromagnet, the filings will assume the form of rods across the cell, in the lines of magnetic force. When the cell is moved across the axis of force in either direction, each rod will rotate upon its axis on the one side to the right and on the other to the left, so as to rotate always

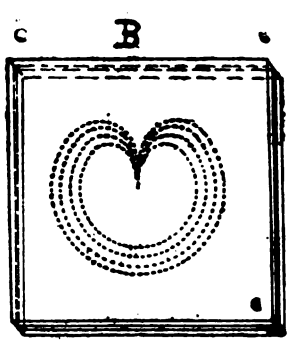

Diagram B.

towards the centre of the field. The diagram B shows the arrangement of the filings when the cell is being pushed upwards.

Supplement.

The conception of the material universe to which I have arrived from an investigation of the nature of gravity is—

(1) That the different forms of matter took their origin in a perfectly homogeneous stuff which occupied space. I

Digitized by Google

arrive at the conclusion that the stuff must have been perfectly homogeneous, because purity of the primary stuff seems absolutely essential to the existence of that state of purity in the elementary bodies which is recognised.

(2) That axial rotation of differentiated quantities of this stuff was originated by *impressed* force, because physical science negatives the idea of any motion being originated in such a medium from within.

(3) That the character of the matter formed depended (*a*) upon the quantity of stuff differentiated, and (*b*) upon the description of axial rotation which it assumed under the stress of other bodies.

(4) That the stuff which is now recognised as ether is the residuum of the uncondensed liquid, which has been very highly attenuated under the stress of formed matter.

(5) That the density of this stuff varies with its relations to the formed matter, being most highly condensed upon the surfaces of the atoms, from which point the density rapidly diminishes until it attains its highest state of attenuation between the largest systems in interstellar space.

(6) That with regard to these axial rotations, the greatest regularity and order is essential to the maintenance of the material universe; indeed, were it otherwise, it would be resolved into the original stuff.

(7) With reference to the influence which stress exercises in the production of rotation, I would call attention, first, to electromagnetic rotations, and, secondly, to the rotation of copper spheres under the influence of electromagnetic stress—a phenomenon which I had the honour of exhibiting for the first time at a conversazione of the Royal Society in 1887.

Again, it is known that each of the planets has a special axial inclination, and this is supposed to be due to the influence which all bodies in the solar system mutually exercise. It is, I think, only logical to assume that the stress which each differentiated portion of the pure liquid exercises must act upon the same principle, and give to each portion of liquid engaged in the production of a mass a special form of rotation around a special axis.

I would further add, that the general principles embodied in this hypothesis appear to do away with all that mystery which hitherto has enshrouded so many natural phenomena.

CITY AND GUILDS OF LONDON INSTITUTE.

LECTURE XIII.—GENERAL DESCRIPTIVE KNOWLEDGE OF MAGNETS AND ELECTROMAGNETS. — BEST METHOD OF WINDING ELECTROMAGNET COILS FOR VARIOUS SERVICES.

(Specially contributed.)

The Natural Magnet.—Rodwell, in his "Dictionary of Science," says: "In Magnesia, a city of Lydia (hence probably μαγνης) a stone was found which, it was well known to the Greeks, had the property of attracting or drawing to itself small masses of iron. The Chinese also, as it appears from ancient manuscripts, were acquainted with this stone, and with certain other properties which it possesses. It is now found in many other parts of the world—in Arabia, China, India, Macedonia, Germany, Norway, and England. It is commonly called *loadstone*, and is known to chemists under the name of magnetic oxide of iron." Chemists denote the chemical composition of loadstone, or, as mineralogists call it, *magnetite*, by the formula Fe_3O_4, which may be read that three atoms of iron (Fe) combine with four atoms of oxygen (O) to form magnetite. The natural magnet is of little or no industrial importance. Its magnetic properties are weak. Whether the power of the natural magnet was accidentally discovered to impart similar powers to hard iron or steel, or whether it was noticed that hard iron or steel do under natural conditions obtain similar properties, I do not know. The discovery is lost in the mist of ages. In the "Arabian Nights" we find mention of the loadstone—poor Sinbad learned its attractive powers to his cost. The important property of the magnet first utilised was its taking a position pointing north and south when freely suspended. Whether this property was first noticed by the Chinese, and came from them through Arabia to Europe, is a question not settled. At any rate the magnet needle is first mentioned by European writers in the twelfth century, and it is rather of this magnet obtained in steel by rubbing with loadstone, or another magnet, or by means of a current, that I shall speak at some length.

Permanent Magnets.—The first systematic investigation of the properties of the magnet was by Gilbert, a native of Colchester, in 1600. Most writers on magnetism jump from the work of Gilbert to that of Faraday in the nineteenth century, and have, most unaccountably to me, ignored the work of such men as Walker at the end of the eighteenth century. I do not intend in these lectures to trouble you much with historical remarks, but must be somewhat lengthy in my references to Walker. With very little emendation, many of his sentences describe the theory of to-day. I have had reproduced as faithfully as photography will reproduce some of the illustrations in his book, and you will see that, so far as these particular illustrations are concerned, they faithfully represent the teaching of the most advanced teachers of to-day. What Walker called a *subtil effluvium*, we call magnetic flux.

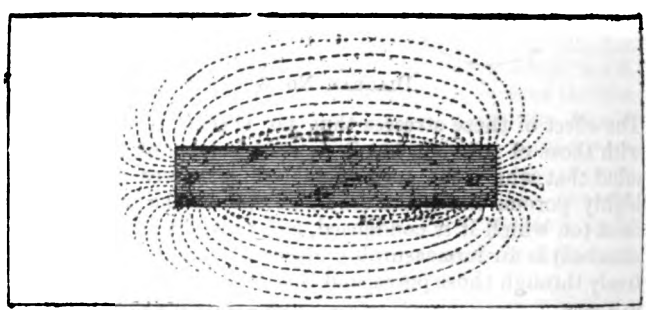

FIG. 1.

Here are two illustrations taken from Walker, and in his book form Fig. 6, plate 1, page 64, and Fig. 6, plate 2, page 64. Of the cause of magnetisation he says: "May we not apprehend this to be occasioned by a subtil effluvium, flowing from one end of the magnet and entering at the other? These two ends are called the north and south pole of the magnet. The reasons we have to believe that this effluvium does exist are:

"First. If wire filings be shaken through a gauze sieve upon a paper that covers a bar magnet the filings will become magnets, and be arranged by the incumbent magnet in the beautiful curves in Fig. 6 [our Figs. 1 and 2]. Upon

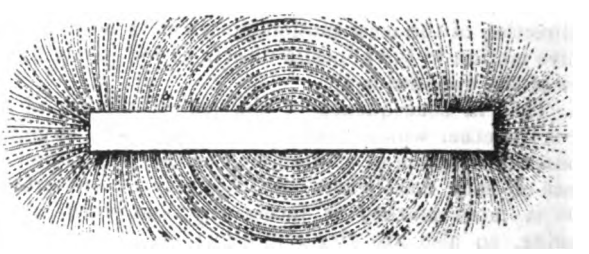

FIG. 2.

the two ends of the magnet at *a a* the filings stand perpendicular, and seem buttresses of arches that would stand over the magnet. On the sides of the magnet they slope or incline, and seem buttresses of inclining arches; so that if filings could be sustained all round the magnet they would probably assume an egg-like figure. Is not this appearance favourable to the idea of an effluvium *flowing all round the magnet from one end to the other and having a circulation through it?*"

There is no difference in Mr. Walker's views as to the subtil effluvium and the modern views of magnetic flux. Let me take as my example of the teacher of to-day Prof. Silvanus P. Thompson, F.R.S., who is *facile primus inter pares*, as Prof. Max Müller puts it. He says, page 40 of his book on "The Electromagnet":

"In the case of a bar magnet we conceive these lines as flowing through the metal, emerging at one end (the north

Digitized by Google

pole) and curving round to re-enter the metal at the other end (the south pole). In Fig. 17 [our Fig. 3] these lines are drawn both internally and externally. Everyone knows that if we dip such a magnet into iron filings the small bits of iron stick on, more especially at the ends, but not exclusively; and if you hold it under a piece of paper or cardboard and sprinkle iron filings on the paper, you obtain curves like those shown on the diagram."

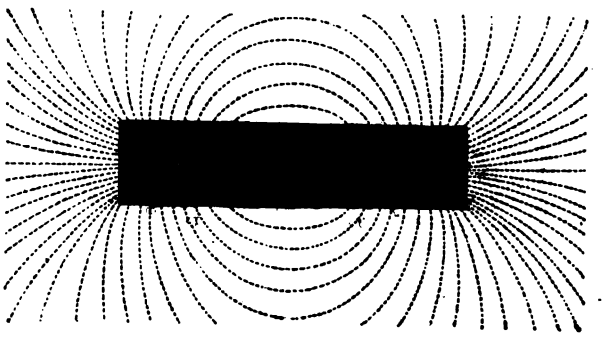

FIG. 3.

If you carefully compare Mr. Walker's diagram with that of Prof. Thompson's, I think you must admit their identity, and also you must admit the identity of the description of what constitutes the magnetic property. The greatest density of lines in all cases is shown to exist at the centre of the bar magnet. The filings do not stick there, as no lines escape from the metal. The filings cling where the lines escape; and where the lines escape most the filings are thickest. It is near the poles that the lines escape or enter most, and it is at these places the filings are thickest.

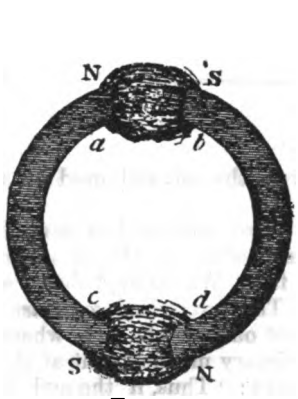

FIG. 4.

FIG. 5.

I cannot recite in detail all Mr. Walker's observations, but his Figs. 8 and 9 (our Figs. 4 and 5) and his remarks about them can be compared with what I said last week. His Fig. 8 is practically identical with my Fig. 3 of last week. He does not indicate the course of the lines through the metal, but what I have said of his views just now shows that he understood the flow to be right through the metal. See how his indicated filings bulge out in the air-gap, just as I explained they do. Here is what he says of these figures, page 45:

"Third. Two semi-circular magnets, A and B (Fig. 8), having their poles dipped into iron filings, the filings will stick radiantly to the poles in every direction. If the pole *a* be brought within half an inch of the pole *b*, and the pole *c* at the same distance from *d*, the filings leave their radiant direction and catch hold of the filings of the opposite poles; for *a* and *c* being delivering poles, *b* and *d* receiving poles, a magnetic circuit is formed, and the filings become conductors. But if the pole *a* be addressed to *c*, and the pole *b* to *d*, the filings will not unite, but repel those opposite to them, as Fig. 9 [our Fig. 5]. In one case the magnetic effluvium has a regular circular road; in the other the fluid of one magnet meeting the fluid of the other a repellency takes place. Are not these experiments strongly indicative of a magnetical effluvium?"

In the following paragraph, from page 46, there is a slip as to the number of balls, but the idea of the magnetic circuit is quite clear:

"Fifth. When three of the balls are suspended from each pole of the above magnet (for except the magnet be very strong it will not sustain more perpendicularly), if two others are so added that they all touch each other, they will adhere circularly to the two poles, and form the image, Fig. 11 [our Fig. 6]. Can this be for any other reason than because the balls and the magnet make one complete magnetical circuit."

Four years before this work of Walker, a more pretentious work in five volumes was written by Mr. George Adams, but although the diagram of the lines of force are

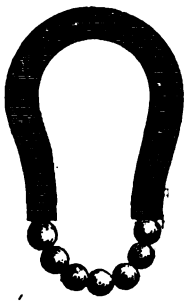

FIG. 6.

excellent, I can find no indication of the idea of a magnetic circuit. Having thus briefly glanced at history, I will return more directly to my subject. Fig. 7 shows the lines of force of the bar magnet, N S. The diagram is

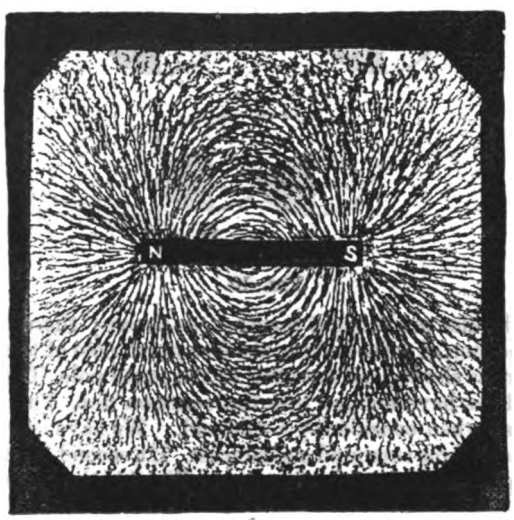

FIG. 7.

from a photograph. If I take any bar magnet, such as N S, and cut it into two parts, each part becomes a complete magnet. If I again divide each part, I again get complete magnets, and we may assume this division to be carried on till we get at last to the molecule of steel, which is the smallest quantity of steel that can exist, and must assume that the molecule is a magnet.

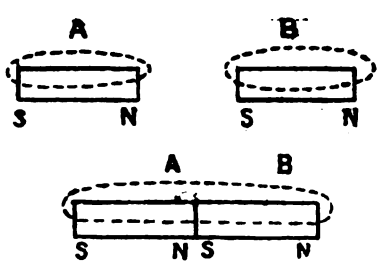

FIG. 8.

If I take these two similar magnets, A and B (Fig. 8), each one has its two poles, N S; but if I bring two of the oppositely-named poles together as shown, the combination forms one magnet with only two poles. I may assume, then, that any magnet is made up of its molecules so arranged that their opposite poles are adjacent, as indicated in Fig. 9, when the shaded part indicates the north pole of the molecule, and the unshaded part the south pole. If the molecules are not arranged in this systematical

Digitized by Google

manner, or so as to form a polarised chain, but in a fashion so that the polarities are lost or masked by forming *complete magnetic circuits within* the boundaries of the metal, we get no external manifestation of magnetism. It is only when the polarised chains or lines are continued outside the

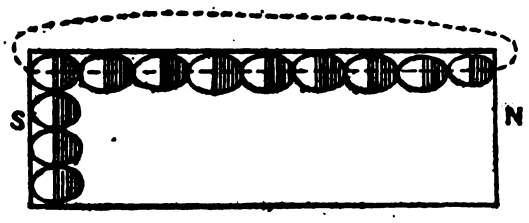

FIG. 9.

metal that we get manifestations of magnetism, and by what medium these polarised chains are continued we do not know. We may picture to ourselves a chain of polarised molecules, the axis of the chain being a line of force.

Although I have no greater authority than myself for suggesting it, let us suppose that each molecule is the seat of one line of force which leaves the molecule by the north and enters it by the south pole, Fig. 10, A and B, and that

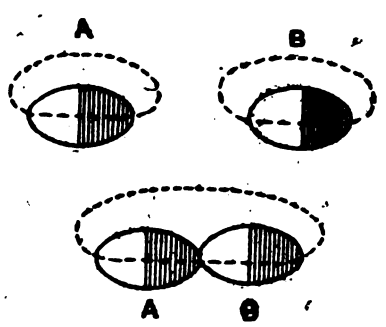

FIG. 10.

two molecules are brought together, as shown; there is still only one line of force leaving the free north pole of the combination, as shown, and entering by the south pole. The individual lines have merged into the common line. This holds good also when considering a solenoid. We have seen that the lines of force surround a conductor. If a second conductor is brought parallel to the first, as in Fig. 11, the lines, as it

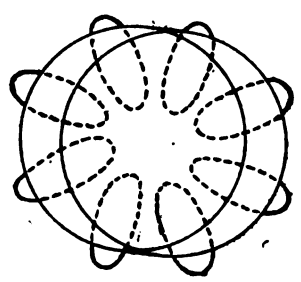

FIG. 11.

were, coalesce and surround both conductors. If a succession of conductors are used, then the lines circulate around all the conductors.

The Making of Magnets.—If I take a bar magnet, A (Fig. 12), and bring into contact with it the piece of

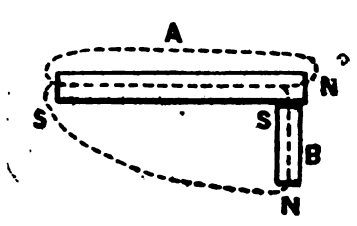

FIG. 12.

iron, B, some of the lines of force of A will go through B, and B will become magnetised with a south pole, S, next the north pole of A, and with a north pole, N, at the other end. In fact, B forms part of the magnetic circuit. If now B consists of very soft iron, when it is taken away from A it practically loses the whole of the lines of force that went through it, and will not act as a magnet when taken away from A; but if it consists of hard iron, or better, of steel, then it will retain many of the lines of force, and act as a magnet when taken from A. The number of lines it would retain, however, under these conditions would be few, and B would act only as a very weak magnet. A better way to obtain a stronger magnet would be to place B, Fig. 13, so that it can be well rubbed with the magnet, A. Let B be as shown, and bring the magnet, A, so that the north pole, N, be placed on the end C of B. Draw A along B to D so that the north pole of A leaves B at D. Raise A considerably above B, and bring the pole, N, down again at C. Draw along B as before. Do this a number of times, and it will be found that B is magnetised so that it has a north pole at C, where it is first touched, and a south pole at D, where the magnet, A, leaves it. There are other ways of obtaining magnets by rubbing steel with a magnet, but a simpler way is to make the magnets by means of a coil. We have seen that the iron core of a coil is magnetised, and just as in the other case, if we use soft iron, the core loses most of its magnetic properties as soon as the current in the coil is stopped; but if it is of hard iron or steel it retains these properties,

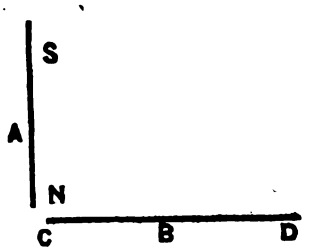

FIG. 13.

and can be moved right away from the coil and used as a magnet itself.

It is possible so to magnetise a bar that it has several poles, though it is absolutely impossible to obtain a bar with one pole. Fig. 14, taken from Walmsley,* shows a bar magnet with several poles. They are called *consequent* poles. The iron filings adhere not only at the ends where we expect them to adhere in ordinary magnets, but at the other polar points. Walmsley says: "Thus, if the end N of the bar be a north pole . . . the region A will

FIG. 14.

exhibit south polarity, the region B north polarity, the region C south polarity, and the other end, N^1, will be found to be a north pole." Magnets with consequent poles have very little industrial use. Such a magnet can be made by rubbing in an irregular manner when magnetising, or if magnetising by a solenoid, by turning the conductor back and winding in the contrary direction at the points the consequent poles are wanted.

A short time ago I indicated that pieces of iron or steel might be naturally magnetised without any individual intending them to be magnetised. From many indications we must assume the earth to have the properties of a magnet—to be a huge magnet, if you so like to term it. Now, if bars of steel or iron be accidently placed in the direction of the lines of force belonging to the earth's magnetic field, these bars will be magnetised. To find the direction of the lines of force of the earth, we use a small magnet so suspended as to be able to move vertically. The axis of that magnet will then take up a position tangential

* "The Electric Current," by R. Mullineux Walmsley. Cassell and Co. The best general book on electricity for students in the English or any other language.—ED. *E. E.*

Digitized by Google

to the line of force of the earth, or it takes up a position so that its lines of force are parallel to those of the earth. Such a magnetic needle is called a dipping needle, and a piece of iron or steel placed parallel to the dipping needle will become feebly magnetised with its north pole at the lower end in this hemisphere. The earth's action on such a bar is very weak, and is assisted by striking the bar with a mallet or something of the kind. The mechanical jar helps the polarising action of the earth. Fig. 15 shows the action of the dipping needle. The upper needle is resting horizontally, as any piece of wire or steel would rest when not magnetised. As soon as it is magnetised it takes up a slanting position, as indicated by the lower needle of the diagram.

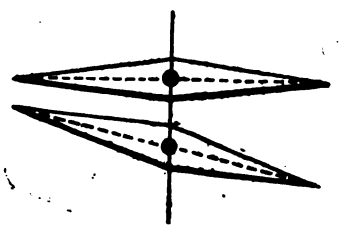

FIG. 15.

The shape of the permanent magnet is not necessarily bar-shaped—in fact, it is usually horseshoe-shaped, in order to utilise the action of both poles. Permanent magnets, too, are usually provided with soft iron armatures, so as to make the magnetic circuit when not in use as short as possible.

ELECTRICAL TRADES SECTION.

The Electrical Trades Section of the London Chamber of Commerce met at Botolph House on the 7th inst., Mr. E. Garcke (chairman of the section) presiding.

After confirmation of the minutes of the section meeting on August 14, the CHAIRMAN stated that several meetings of special committees had since been held, and as regards electric traction it was expected that the syndicate interested in the matter would shortly demonstrate their system by means of a vehicle on the streets, and that it would thus be brought under the notice of the Board of Trade and the Home Office. The chairman read a letter from Mr. R. P. Sellon with reference to the objections raised before the Board of Trade by the London County Council to the placing of transformer-chambers in the public streets, on the grounds that they formed a serious obstruction in the roadway which might interfere with future gas, water, sewer pipes, etc., and that they constituted a grave public danger. It transpired that the Board of Trade regarded the matter of such importance that its further consideration had been postponed until the 13th inst., to enable those concerned to appear by counsel or bring expert evidence in support of their contentions. The bodies represented at the meeting at which the matter was raised were the London County Council and the local authorities of Islington, Hampstead, St. Luke's, Wandsworth, and Kensington, as well as the County of London Company. The feeling of the latter company was that the question concerned all who were connected with electricity supply where transformation was necessary.

After remarks by Mr. R. P. SELLON and Mr. SIDNEY MORSE (who was of opinion that there would be less difficulty in meeting the objection on the ground of obstruction than that of public safety), it appeared to be the general view of the section that it was desirable that the interests of supply companies and others concerned should be represented at the enquiry, especially in view of the suggestion that transformer-chambers be placed in private property only. A resolution was therefore agreed to, at the instance of Major FLOOD PAGE, seconded by Mr. BULL, to the effect that the section was unanimously of opinion that the transformer-chambers in the streets would not be dangerous to the safety of the public, and could be constructed so as not to form any serious obstruction to the future use of the streets for other necessary purposes, and that representations be made to the Board of Trade to this effect.

The section approved of the terms of a draft circular letter to the supply companies, as a result of meetings of a special committee as to the manner in which such companies were likely to be affected by the incidence of local rates. It appeared to the committee from several cases which had been brought under their notice that the rating authorities were becoming alive to the fact that electric lighting companies, whose capital was not always obtained from the locality, might be made to contribute large sums in the way of rates, and thus lighten the burden of capitalists residing in the districts in which the electric light stations were situated. The enormous increase in the assessment of the St. James's and Pall Mall Electric Supply Company were detailed in the circular, which invited other companies to forward information to the secretary with a view to concerted action being ultimately taken in the interests of all concerned.

Mr. SIDNEY MORSE called attention to the methods adopted in the courts of hearing motions involving electrical questions, and the subject was deferred until the rules of the new Commercial Court have been obtained.

It was agreed that in future the meetings should be held on the first Friday in the month, commencing with January, 1895.

INSTITUTION OF ELECTRICAL ENGINEERS.

The following is the house balloting list for Council and officers for the year 1895:

PRESIDENT.

R. E. Crompton, M.Inst.C.E.

VICE-PRESIDENTS (*four to be elected*).

Sir David Salomons, Bart., M.A.
Sir Henry Mance, C.I.E., M.Inst.C.E.
Prof. George Forbes, F.R.SS. (L. and E.)
Robert Kaye Gray, M.Inst.C.E.

ORDINARY MEMBERS OF COUNCIL (*12 to be elected*).

Major A. H. Bagnold, R.E.
Frank Bailey.
W. B. Esson.
Walter T. Goolden, M.A.
Prof. A. B. W. Kennedy, LL.D., F.R.S., M.Inst.C.E.
Prof. John Perry, D.Sc., F.R.S.
Augustus Stroh.
James Swinburne.
*G. von Chauvin.
*S. Z. de Ferranti.
*William E. Langdon.
*Prof. S. P. Thompson, D.Sc., F.R.S.

ASSOCIATE MEMBERS OF COUNCIL (*three to be elected*).

*Augustus Calder.
*Captain George Carr, R.E.
*J. M. V. Money-Kent.

HONORARY TREASURER.

Sir David Salomons, Bart., M.A. (Vice-President).

HONORARY AUDITORS.

Frederick C. Danvers, India Office, S.W.
Augustus Stroh.

HONORARY SOLICITORS.

Messrs. Wilson, Bristows, and Carpmael, 1, Copthall-buildings, E.C.

* New members recommended by Council.

Telephony in Germany.—Direct telephonic communication has been established between Chemnitz and Leipsic, by which the service which was previously carried on through Meerane has been expedited. It has also allowed of Döbeln, Waldheim, Mittweida, Frankenberg, Zschipau, Annaberg, Bucholtz, Lugan, Stollberg, and Burgstädt, which are connected to Leipsic, being able to communicate with Chemnitz. They were not formerly in a position to do so owing to the heavy traffic on the Meerane line.—A telephone exchange has been established at Celle for the town. It is also connected with Hamburg and Hanover.—A telephone system has been established at Nauendorf in the Saal district, comprising Nauendorf, Löbejun, and Wettin. The system has connections with Halle, Leipsic, and Berlin.

United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

TRACTION HORSE-POWER.

It is perhaps not unnatural for those who have never studied the details of electric traction to wonder why it is that the generating plants installed at supply stations for operating electric tramways are usually calculated on such a generous, if not excessive, basis, when the number of cars on the line is taken into account. For engineers to be surprised at the apparent discrepancy shows, however, that they do not believe in, or bear in mind, the comparatively high efficiency of electric traction—otherwise they would see that no real discrepancy exists at all. If this efficiency is as stated, there can be no such excessive waste of power in the generating plant, and the simple fact is that the electric cars travel at a higher speed and carry more load up heavy grades at high speeds—that is, in short, do more work—than would be possible with horse cars. If all this extra work is done for poor returns, then that is the fault of bad management or traffic superintendence; but it is absurd to say that electric traction is wasteful because the output from the generating station per car on line may reach a maximum of thirty or forty amperes—that is, from twenty to thirty horse-power—whilst an ordinary horse car is worked by a couple of animals. The dynamometer is too seldom used on horse cars, or it would then be admitted more freely that the strains at starting or running uphill are in exact accordance with the demands of load and speed, whether the cars be driven by animal power or mechanical appliances. It must be remembered, moreover, that from ten to twelve horses are allotted to each horse car, and this represents as great a maximum horse-power in the stables as in the generating station, per car in service, for in starting the animals (as everyone knows) exert far more than a single horse-power each.

In a recent issue, one of our contemporaries published an article which treats of this matter in the defective way we have thus outlined: and we think it is to be regretted that the respective cases should not be put more fairly. Quoting from an American source, it speaks of a generating station with three two hundred horse-power boilers and corresponding steam plant for a line nine miles long, with a half-hourly service, thereby involving the use of only four or five cars: it then asks "How would the four cars look with one hundred and fifty horses to each? Even if one boiler alone be worked, this implies a capacity of fifty horse-power for each car at work." Criticism such as this does not do electric traction even bare justice. In the first place, it is quite erroneous to assume that because three large boilers are installed, therefore the small traffic named will require all of them to be used. One such boiler would be ample for the work; and if more are put in, the fault must be placed at the door of the man who designed the station. He may have been instructed to build for future traffic, if the neighbourhood is a growing one, or there might be numberless other reasons. The proper course is to assume nothing but facts, and to go by the plant actually required and used rather than the available capacity of the station.

Digitized by Google

Assuming, however, that one boiler alone is employed, then the maximum output ever demanded from it, if all the cars were starting simultaneously or ascending steep grades in unison, would not reach its full load at, say, thirty horse-power per car—a very fair allowance. Yet if horses are employed, there must be kept at least ten or twelve for each distinct car, and the violent strains to which they are subjected make their life so short that the annual renewals will reach very nearly 50 per cent.

For lines where the traffic is small, the maximum output is notoriously much higher than the average, and for any number of cars on line up to, say, ten, it is advisable to allow for a maximum of thirty amperes per car. When we have one hundred cars to deal with, the economy is much more marked, and twenty amperes per car would probably be ample. The use of two motors with each car, coupled in series, then in parallel, as now universally adopted, has helped to bring down the average power per car enormously, as will be very evident to all those who have seen diagrams of the current consumption on such lines, and in traffic where motor regulation is effected solely by the use of resistances. This appears to be another piece of evidence against the too common idea of cable traction being superior to electricity where large traffic has to be coped with.

TRANSFORMER-CHAMBERS.

It may be considered that the question of the position of transformer-chambers could have little interest or evoke opposition, but such seems to be not the case. Various authorities are opposing the construction of such chambers in the streets on the score of possible interference with the laying of gas, water, and other pipes in the future, and their danger. Let us consider the latter first. The various parties interested in transformer-chambers cannot prove a negative. They may point out that no accidents have happened, they may point out that no reasonably competent man will admit the possibility of accident, they may insist that this word "danger" is merely the bogey which all opponents of the electrical industry trot out upon every possible occasion—but all this leads nowhere. What is a transformer station, and what are the accidents put forward as possible? It is a chamber containing transformers, things made of iron and copper, with some combustible insulating material. Suppose a transformer burns out, what is the danger? A little flame, a great stink, and darkness of the lamps on the secondary circuit. The flame won't hurt because there is nothing to burn. The lamps being out is not a danger in the sense of personal injury at the transformer station. There is the bogey of shock. Well, in the first place, no person unconnected with the work ought to enter a transformer-chamber—and it is not, we hope, suggested that someone may get a shock outside the chamber. At any rate, if this is the argument, the position of the chamber won't make much difference to the possibility, which, however, we deem non-existent. The real opposition comes from those interested in "gas and water and other pipes." Even supposing—a supposition which we deny—that transformer-chambers did in some way interfere with these "pipes," it may well be asked if these pipes have a claim for all time upon the under street portion of the earth. Are civilisation and progress played out, that gas-pipes, for example, claim not only what strip of earth they do want, but also some small cubical area they do not now want, and may or may not want in the future? A few of the streets of London and in one or two other towns are pretty extensively utilised below the surface, but the opponents of electric lighting are not contented with suggesting that in these particular streets—say, twenty miles or so all told—exception to ordinary practice may be required, but would impose disabilities everywhere and under all circumstances, even in an eighty-foot carriageway, when twelve feet only are used for gas and water mains. We admit exceptional cases call for exceptional procedure, but for the Board of Trade to be asked to promulgate a general order rigidly defining what shall be done in all cases savours somewhat of the absurd. The result of the enquiry at the Board of Trade on the 13th inst. should be in favour of admitting transformer-chambers duly constructed under the streets because they neither interfere with traffic nor, with certain exceptions, with existing pipes, nor are a source of public danger.

THE INSTITUTION COUNCIL LIST.

This list has just been issued to members, and on the whole will no doubt be approved. There is evidently a desire to represent all interests upon the Council, but there is also as evidently a tendency to over-represent some interests, and to permit considerable lag before awakening to the rise and progress of other interests. It is too late this year to attempt an organised substitution of any other names than those proposed. Last year the Council was somewhat peremptorily pulled up for its neglect of cable interests. This year an effort has been made to avoid adverse criticism in that direction. What we desire to call attention to is the lack of appreciation of the importance of municipal electrical engineers. These men will soon number a formidable body, and not only will their numbers be large, but their influence will be greater. They will have among them all the best of the practical men, and will have at their fingers' ends the up-to-date practice of the industry. They will represent the largest moneyed interests, before which even the millions of the cable companies will take second place. It would seem but natural that the Council of an Institution whose motto should be progress would realise all this, and would hasten to have among its members a good representative of this body. But it is not so. The municipal engineers are ignored, and one name at least is found upon this list that has no claim to be thereon. We cannot but think this view of the question has not been presented to the Council when framing the house list, otherwise it is difficult to account for no name representing this class

Digitized by Google

appearing. The difficulty of pleasing all parties is very great, but the list includes no less than six or seven representatives of manufacturers—viz., Messrs. Crompton, Kaye Gray, Esson, Goolden, Swinburne, Ferranti, and Money-Kent. Probably these names should be reduced to six by taking Mr. Kaye Gray as a representative of cable interests, than whom indeed no better representative could be found. The manufacturers' interest is great, but not so preponderatingly great as this number indicates, and one could have been spared to enable the municipal authorities to be represented. We do not wish to be misunderstood. There is no desire to disparage in any way the name of any man on the list. No doubt each will do yeoman service. Our aim is simply to urge the representation of all branches of the electrical industry.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTRIC LIGHTING OF HARROW.

SIR,—A statement appears in your last number regarding the scheme for electric lighting at Harrow which is rather confusing, and I shall be glad if you will allow me to correct the same.

The state of affairs at Harrow is this: The local authority, having considered the question of electric lighting, decided to invite tenders. A specification was drawn up by me and sent to 10 of the leading firms of contractors. After carefully considering the tenders sent in, the Board decided that that of Messrs. Crompton and Co. was the most suitable, and they accepted the same provisionally. Promises of support of the Board's scheme were received from the house masters of Harrow School and others, and the Board wrote to the head master to ascertain if the governors of the school would introduce the light into the school buildings. The head master replied that the governors would be prepared to favourably consider the proposal for lighting the chapel, library, and other school buildings, provided they received from the Board full particulars as to the probable cost of the lighting. Messrs. Crompton and Co.'s tender was to the local authority for generating plant, mains, and street-lighting, and has nothing to do with the lighting of the school buildings, as would appear from your note. Will you kindly make the correction as soon as possible, as it has already caused some confusion?—Yours, etc.,

W. C. C. HAWTAYNE,
Consulting Engineer to the Local Board.

3, Princes-mansions, Victoria-street, S.W., Dec. 4, 1894.

MADRID LIGHTING.

SIR,—There have been several reports recently in the electrical journals of the repeated breakdown of the electric light supply in a portion of Madrid, and I find that many persons are under the impression that the Electricity Supply Company for Spain, Limited, is referred to.

As the above company is fully equipped with English plant, manufactured by my company, Messrs. John Fowler and Co., of Leeds, and the Electric Construction Company, of Wolverhampton, I think it only fair in the interest of all to ask you to correct this impression in your valuable paper.

The English company has not broken down, but has continued to supply light without intermission, although during the progress of the 50 per cent. addition to its plant last year, the machinery supplied in 1890 was often loaded quite 10 per cent. above its normal capacity, in consequence of the rapid increase of business.

The plant which has failed is that of a company financed by a German syndicate. It was manufactured in Belgium and Germany, and is on the low-tension continuous-current system.—Yours, etc.,

P. A. LATHAM, Secretary,
Leeds and London Electrical Engineering Company, Limited.

London, E.C., December 6, 1894.

ELECTRIC LIGHT AND POWER.

SIR,—I note in your issue of last week a report of a lecture given by me at Warrington. I beg leave to state that the report was not authorised by me, and that for the concluding sentence, in particular, concerning smoke abatement, which has provoked ironical remarks in a contemporary devoted to the gas industry, I will not hold myself responsible.—Yours, etc., FRANCIS G. BAILY.

University College, Liverpool, December 2, 1894.

ELECTRIC TRACTION.

SIR,—The question of electric traction has been discussed for some years. Is any practicable system known by which dust-vans can be propelled at a cost which is not prohibitive?—Yours, etc., T. W. E. HIGGENS.

Town Hall, Chelsea, S.W., December 4, 1894.

REVIEWS.

American Electric Street Railways. By KILLINGWORTH HEDGES, C.E. London: E. and F. N. Spon.

This book is another instance of the *parvum in multo*, with an elaborate crimson binding and gilt embellishments. It might from exterior appearance rank with an *edition de luxe* of Doré or Ruskin, but wide margins, good paper, and tolerable printing make a brave show that is not by any means maintained in the substance of the book or the methods adopted by the compiler. We use the latter term advisedly, inasmuch as the greater part, if not all, of the book consists solely of reprints and quotations from different sources bearing upon electric traction. This very fact, however, tends, of course, to give the book a certain value, since a great many engineers may be glad to have in a form easy for reference information and facts, perhaps, at present lying loosely on their book-shelves, as press clippings, etc.; but whether they will pay so heavily for elaborate binding and printing is a question for time to decide. We cannot help thinking that the public—being mostly foolish—is far too easily led by the nose in these matters, and books are bought for their outside appearance instead of their sterling worth. This has the bad effect of encouraging many incompetent authors and discouraging a number of those with some power of original thought, for publishers are apt to please the eye in order to sell (*vide* recent *Times* correspondence).

The "scrap-book" character of this work is an advantage when the material is drawn from reliable sources; and as trade lists, with working instructions, papers read before societies, and articles contributed to various journals by different writers which largely compose its pages are tolerably representative of good practice, we should be unfair to their respective authors if we did not acknowledge such value as they may have. In those places where Mr. Hedges treads alone we cannot compliment him in the least upon his scientific accuracy, nor yet award praise to the general scheme of this book. What does he mean in the preface by "staring advertisements greatly increasing the dead-weight"? And what grounds has he for dealing so glibly with the question of municipal control? We doubt very much whether corporations *will* grant new licenses, and still more do we doubt whether tramway companies will desire new licenses under the existing law, except on the principle that half a loaf is better than no bread at all.

In describing the action of electric motors, electrical engineers will probably feel that they know better than the teaching here given, whilst surveyors, municipal engineers, or the non-technical public will inevitably be mystified and befogged by the statements. Thus we read of "the attraction of the magnets causing the armature to re-

Digitized by Google

volve . . . because the magnet attracts each coil of the armature," etc.; then directly afterwards, "it is not *the coils* which are attracted by the magnet, but the influence of the latter on the *current of electricity* which flows through these coils of copper wire" (the italics are Mr. Hedges's). Of countless other loose or incorrect statements, we may note these: "One of the new forms of alternating currents, called the 'multiphase,' in which the electricity is generated in waves." "Current passes through the gunmetal wheel, which is usually either of 5¾in. outside diameter, but sometimes only 4⅜in.," etc. We might go on quoting indefinitely, and commenting even more strongly. An erroneous description of three-wire running is evidently taken from the diagram—which is wrong—there being no connection shown between the rails and middle wire. The method of winding large generator armatures "is a sort of 'Drum' and 'Siemens's' winding applied to a ring core." This, to say the least, is hardly a lucid description. Mr. Hedges found a "lightning generator" at the Minneapolis power station: another piece of evidence that we are behindhand in traction matters over here. Then he says that high-speed engines are in a measure out of date for railway work: does he mean engines running with high piston speed or a high number of revolutions per minute? Some of the Corliss engines running at 80 to 100 revolutions per minute have as high a piston speed as a Westinghouse or Willans.

These few instances will serve as types of the crudities in this book; the final point which we have space or inclination to criticise lies in the loss of excellent opportunity by Mr. Hedges in the book of initiating improvements upon the barbarous terms and slang used by the Americans for tramway purposes. We say nothing about "street railway" for "tramway"—these are tweedledum and tweedledee (except that our word has the merit of shortness)—but it is much to be hoped that on this side we shall speak of "hangers" instead of "ears," "cut-outs," not "circuit breakers," "resistances" instead of "current diverters," etc.

Mr. Hedges's glossary of technical terms is carefully to be avoided if real knowledge be sought. There is hardly a single definition upon which we can congratulate him as logical or complete. The idea, moreover, of defining "indicator diagram," "road bed," and "motorman"!

Taken all in all, we should say that this book will only be of service as a compilation of matter which ought to have great intrinsic value, and is certainly worth more trouble than has been taken to put it together so as to avoid the trouble of search.

An Introduction to the Theory of Electricity: with Numerous Examples. By LINNÆUS CUMMING, M.A. Fourth edition, with Corrections and additions. Macmillan and Co.

Since the first edition of this book in 1876, the subject of electricity has become of world-wide interest. Then there was no electrical industry. The industrial applications were restricted to land and submarine telegraphs. Students of what we may call the higher science there were few or none. Our views have expanded since then, and the schoolboy of to-day has a better knowledge of the science than the prominent members of the telegraphic world of that day, and yet their knowledge in various directions was extensive and accurate. The various editions of this work have always been fairly up to date, and looking upon it as an elementary mathematical treatise for students, it would be difficult to find any work in which the propositions are more clearly stated or more elegantly solved. We might in some cases differ as to definitions, but once granting Mr. Cumming's definitions, the student must be charmed with the method of treatment. We might also prefer a very different method of treatment of the subject, but it is difficult to point out wherein we would have this treatment altered. To those who have used the previous editions, we can say that the alterations and additions have increased the value of this edition. To those who have not used the book, we would say it treats the subject more by giving solutions to various propositions than by attempting any physical explanations of phenomena. It gives, in fact, a mathematical expression for the result, accepting the accuracy of the premises, as stated. It is essentially a school or college text-book, and not a workshop manual. In its own sphere it is excellent.

SLIDING ROOF FOR THEATRES.

In our issue of November 23 we referred to the introduction at the theatre and concert hall—"La Cigale," in the Boulevard Rochechouart, Paris—of a sliding roof worked by electric motors. A few further particulars concerning this somewhat new departure should be of interest.

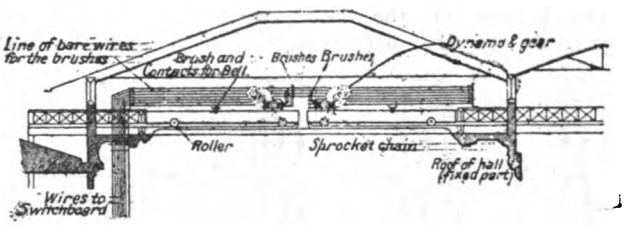

FIG. 1.

The oval roof of the hall is divided into two parts, each of which is carried on four rollers travelling on a track, as shown in Figs. 1 and 2. When once open, the movable parts of the roof travel and press upon two sheltered platforms placed one above the stage and the other above the entrance hall. The rollers nearest to the centre of the roof are arranged on each side on two axles, which are put respectively into motion by means of a sprocket chain and a train of gearing, the latter including a pinion arranged on the shaft of an electric motor, as indicated in the illustrations. The arrangements are due to Messrs. J. Julien and Co. and Mr. Pacoret.

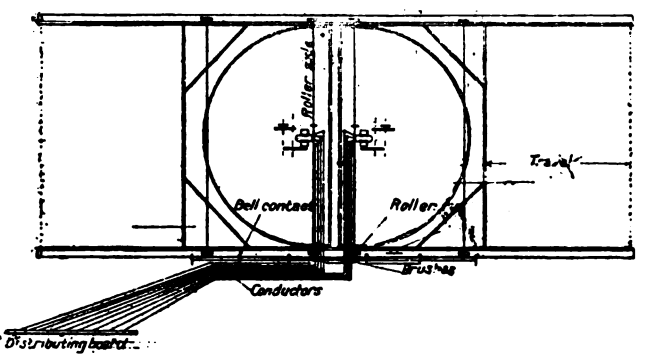

FIG. 2.

The position from which the travelling bridges or sliding parts of the roof are operated is at the distributing switchboard in the entrance lobby, where it is impossible to see either the roof or the hall. It was therefore necessary to design the installation in such a manner that the attendant would know at what moment to stop the motor either on the opening of the roof or on closing it.

The current is obtained from the Edison Company's mains, and the connections on the board are shown in Fig. 3. The two motors, one arranged on each side of the roof, are of the Hillairet-Huguet type, series wound; they are calculated for a speed of 1,000 revolutions at a pressure of 110 volts, and are capable of absorbing 10 amperes. On one side of the roof below the track are suspended seven bare copper wires, upon which rub sliding contacts fixed to the two parts of the bridge. These wires are numbered, and are connected to insulated conductors leading to the switchboard from which the roof is operated.

The two circuit wires connected to the Edison mains are brought in through a double-pole cut-out protecting a two-pole switch, which is not shown. From this switch one of the conductors is led to two switches, or magnetic cut-outs, which are regulated in such a manner that the circuit of each motor is automatically opened if the intensity of the current exceeds 10 amperes. Leaving these appliances, the two circuits are conveyed each to a changing switch having suitable resistances for regulating the current. These changing switches carry two

Digitized by Google

movable contacts which are insulated from each other; the upper is for putting in or out of circuit a smaller or larger amount of resistance, and consequently varies the intensity of the current, this corresponding to alterations in the speed of the motors. Moreover, it assists the lower one in serving as reverser, and in changing the direction of the current in the armature without altering that passing through the magnets in such a manner as to assure the change of the direction of rotation of the motors. In the positions occupied by the changing switches, as indicated in the diagram, the switches are out of circuit, and no current traverses the motors, which are, of course, stationary. The two large semi-circular segments placed at the bottom of the two switches are connected respectively to the bare wires Nos. 5 and 3; the

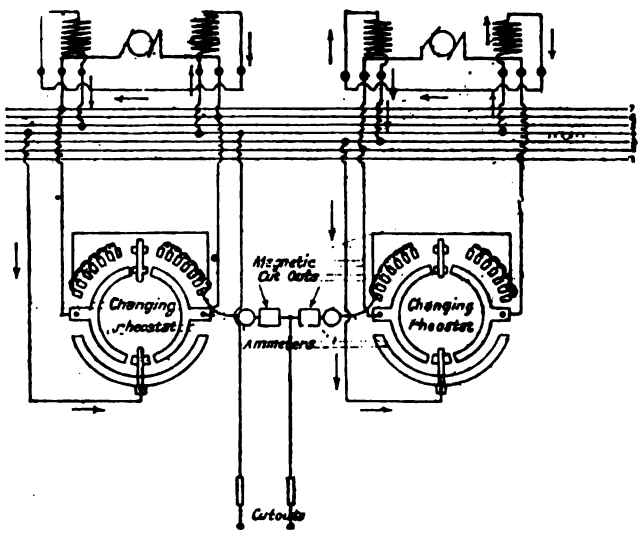

FIG. 3.

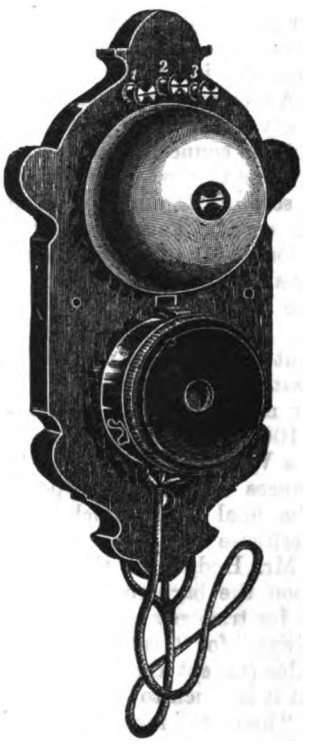
brushes connected at the entrance of each of the armatures make contact on these wires; the two exits make common contact on wire No. 4. The latter wire is, moreover, in permanent communication with the conductor connected to the main. Two ammeters allow of the fluctuations in the current being followed, and consequently of the rheostats being manœuvred. The brushes of the left armature make contact on the wires Nos. 6 and 7; those of the right armature on the wires Nos. 1 and 2. The working of the changing switches connect these four wires respectively, sometimes in one way, sometimes in another, with the general circuit.

On starting, the motors absorb between nine and ten amperes, but once in operation the current used ranges from five to seven amperes. The operation of putting the sliding roof in or out of position is effected in less than one minute at a cost of about one penny.

Arranged upon the two halves of the roof and on the vertical face of the bridge are two contacts, which shortly before each part of the roof reaches the end of its travel press upon two buttons, each actuating an electric bell placed under the switchboard. The latter are arranged in a battery circuit, and on ringing they indicate to the attendant first that stoppage is near (which allows the man to manipulate the rheostat so as to diminish the speed, and, secondly, on ceasing to ring, that the sliding parts have reached the end of their course, the contacts having passed over the buttons. If at this moment the attendant were to forget or neglect to interrupt the current, it might happen, the motor being unable to revolve because of its being wedged up, that the current would reach a value which would put the motor out of use. At that moment, however, the magnetic cut-out acts and breaks the circuit. This apparatus is simple, and works well. We are indebted for the foregoing particulars and annexed illustrations to our contemporary *L'Electricien* of November 24.

THE NEW "STENTOR" TELEPHONE.

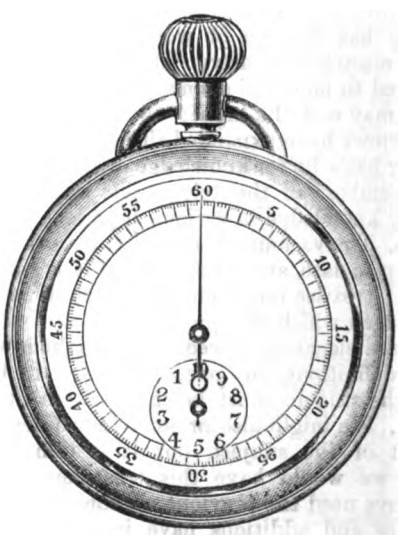
In the annexed illustration is shown the new "Stentor" telephone, which, we are informed, has been very favourably received by the trade. This instrument is essentially for domestic use, being very suitable for service in business offices, hotels, factories, and private houses. Take, for instance, the case of hotels. One of these telephones fixed in a bedroom allows of an order to be given direct to the attendant without the necessity of the latter proceeding to the visitor's room to ascertain the latter's requirements. It is claimed that the instrument's granular microphone is the most sensitive, loud-speaking, and perfect transmitter yet produced; that it requires



in most cases not more than one, or, on long distances, two cells to work it; and that it lends itself specially to replace the old style of electric bells and pushes, its cost being very little in excess of that of an electric bell installation. The "Stentor" telephone, which can be easily used on existing bell lines, is made in two sizes by the International Electric Company, of 55, Redcross-street, Barbican, London, E.C., who report that repeat orders for the instrument are being constantly received.

NEW CHRONOGRAPH.

The annexed illustration shows a small chronograph which has been brought out by Mr. R. W. Paul, of 44, Hatton-garden, E.C. It is an ingenious instrument which is intended for the use of students and experimenters in timing experiments. The



chronograph, which reads in fifths of a second up to 10 minutes, is started by pressing the button at the pendant, and is stopped instantaneously by repeating that operation. After taking the reading the hand flies back to zero on pressing the button a third time, when the chronograph is ready for use again.

Digitized by Google

ELECTRICITY ON BOARD SHIP AND ITS APPLICATION AS MOTIVE POWER FOR AUXILIARY MACHINERY.

I am very much alive to the fact that naval architects are placed at a great disadvantage, if they are not entirely prejudiced, in forming an opinion as to the merits or demerits of electrical apparatus and methods. In the first place, their judgment is liable to be warped by the very plausible way in which each manufacturer nowadays, driven by keenness of competition, claims for his own particular apparatus some technical superiority. This is, of course, very bewildering except to an electrical expert. But further in this connection, it is to be observed that as yet there is a marked absence of any extensive installation of electrical machinery in the fleets of the present day. This effect of competition has not been so keenly felt in the sphere of electric lighting as it has in the direction of the application of electric power to the auxiliary machinery on board ship, for the simple reason that electric lighting has made great progress, and obtained a substantial footing on land, and the naval architect has consequently brought himself to conform to public opinion and provide a place in the ship for the necessary dynamo. On the other hand, the improvement and development of electrical machinery for the transmission of power has not been a question of public interest or public demand. But we must look yet further to discover what other circumstances have militated against a more extensive adoption of electrical machinery on board ship, for it must be admitted that electrically-driven machinery is, and has been for some considerable time, in successful operation on land. Undoubtedly, one of these circumstances is the fact that what would be a suitable design in the one case might not be at all appropriate for a similar purpose in the other, and therefore the development has been slower. Another of these circumstances is a deeply-rooted suspicion on the part of those actually interested in navigation that the magnetic action of the electric current affects the compasses. This idea is, however, gradually being dispelled. A better class of electrical work is being done, obviating all danger in this direction, and more scientific officers are gradually taking the place of the old hands who first witnessed the introduction of electricity into the naval service. Another adverse circumstance is that owners of vessels which have been fitted with the electric light have had a somewhat unenviable experience. The installations have been fitted up by contract in a very large number of cases, especially in the smaller class of steamships, with regard only for making the most profit out of the job. This has led some shipbuilders to permanently employ a qualified electrician to look after their interests, and the result has been a much better execution of the details of the work and improvement also in the quality of the material employed. Another circumstance which accounts in part for the non-development of marine electrical machinery is undoubtedly the absolute reliance which has to be placed upon the action of the auxiliary machinery; in connection with it should be mentioned that skilled labour also would have to be employed in operating some portions of it. This, however, does not apply to all the mechanical work that might be done by electrical methods, as I will presently show.

Each of the three circumstances to which I have referred is sufficient in itself to account for tardy progress in the use of electrical transmission of power on board ship. It is no wonder, therefore, that as yet we have not a single instance in which the electrical engineer and the naval architect and shipbuilder have collaborated to design and arrange the machinery with a view to supersede steam-pipes by electric cables for auxiliary purposes. But if there has been no collaboration, electrical engineers have, nevertheless, set themselves separately to the task, and it is the result of their efforts which I will endeavour to point out. The following is a list of the auxiliary machinery to which electricity has been applied as a motive power: electric winches, electric cranes, electrically-driven lathes, electric steering-gear, drills, capstans, refrigerators, fans, pumps, and ash-hoists. These may be divided into two classes—viz., (1) those which have been specially designed for use on board ship; (2) those which have been proved practically successful for land purposes, and which could readily be adapted for use on board ship. In the first list may be classed electric winches, cranes, steering-gear, capstans, and fans. In the second list may be classed electrically-driven lathes, electric drills, refrigerators, pumps, ash-hoists, etc. Having described Siemens's electric winches, Crompton's electric winches and cranes, Siemens's electric steering-gears, drill, and electric capstans, and Holmes's electric fans, the author said:

I have now pleasure in drawing your attention to the fact that an experiment is about to be carried out in Hull with electric winches. I am enabled to give you a few particulars, through the kindness of Mr. Spear, who proposes to make the trial on one of Messrs. Wilson's boats. The motor designed by Messrs. Crompton and Co. will be supplied, and the entire work carried out by Mr. H. S. Tadman, who has also kindly given me details of the construction of the winch. As an experiment between Mr. Spear and Messrs. Crompton, a departure from adopting the special designs of electric winches has been made, inasmuch as they are going to convert an ordinary winch fitted with steam power into one driven by electricity, substituting the steam-engine portion by an electromotor, which will, of course, be adequately protected. This is a point of economy, as of course to discard an entire arrangement would be an expensive matter, and where a large portion of the machinery is not required to be altered, there is no necessity, in the case of existing vessels, to make an entire replacement.

I will now endeavour to point out a few of the advantages arising from the substitution of electricity for steam or hydraulics as a motive power for auxiliary machinery. In the first place, let me remark that I am quite aware of what has hitherto been considered the great drawback to the employment of electromotors on board ship. I refer to the attention which the commutator and brushes undoubtedly require; but in admitting this, I must confess I am of opinion that a great deal too much prominence has been given to it, and that the attention required has been unduly emphasised. It should be considered side by side with the necessary repairs to steam plant, just in the same way as the actual working costs and efficiencies of the respective systems are compared. Here I may incidentally remark that such comparisons are quite overlooked by those whose knowledge is limited to that of one system; the hope that steam will be supplanted by electricity for auxiliary purposes is really based on the fact that the present candidates for marine engineering situations possess a fair knowledge of what are the actual facts concerning electrical apparatus. Repairs to the auxiliary machinery on board ship are mainly necessitated by the reciprocating action of the steam-engines, which in suddenly starting and stopping put abnormal and undue strains upon the gearing or load. This is especially the case with steam winches and cranes, where a sudden jar frequently breaks the teeth of spur and bevel wheels, upon the repair of which the engineers are constantly engaged. While I am speaking of commutators and brushes, it will be as well to remind you that the development of electrical apparatus does not stop short at the generation of continuous currents, which perforce require a commutator and brushes. By the use of polyphase currents, commutators and brushes are entirely superseded. Polyphase currents are alternating in their nature, but they are quite distinct from the high-tension single-phase alternating current which is used extensively for electric lighting from central stations. The starting of polyphase motors is effected electrically and automatically under much the same principle as a compound engine is started by steam—that is to say, no initial momentum has to be given by means of a flywheel or other arrangement. Polyphase motors can be as easily started, stopped, or reversed as those of continuous currents, and the only attention required is to see to lubrication. Polyphase currents are also equally serviceable for lighting and power.

The most important advantages, however, of electric motive power may be considered under two headings—viz., motors *v.* steam-engines, cables *v.* steam-pipes. In the first place, I will briefly enumerate the advantages under the first heading, which are as follows: (1) Greater facilities in starting, stopping, and reversing consequent on a rotary instead of a reciprocating motion, and obviating the evil effects of condensed water in steam-cylinders, etc. (2) No leaky drain cocks, defective stuffing-boxes or glands. (3) Noise in working is reduced to a minimum, which is a matter of considerable importance in passenger vessels, where cargo is loaded and unloaded at night, and where the cranes and winches are frequently in proximity to cabins. (4) Less coal per brake horse-power, due to the highest efficiency of an electric motor as a converter of energy, taking into consideration only the diminished losses of power in working one large instead of several small steam-engines. On board ship this is very largely a question of temperature. For instance, a 50-h.p. steam-engine driving a dynamo would be placed in some position adjoining the boiler-hold and engine-room where the temperature is always fairly high. The engine running constantly, we may take the efficiency of the brake horse-power to be 8 per cent. for any load. Under such circumstances the useful energy applied to any of the auxiliary machinery, including the conversion from the dynamo to the motor, at any proportion of load not less than one-fifth, would be at least 80 per cent. of that developed by the steam-engine, or a total steam efficiency of 6 per cent. With the use of small steam-engines, however, to drive the auxiliary machinery direct, even assuming the boiler pressure to be maintained to the cylinders of the engines, an additional loss occurs of 50 per cent. of the heat energy of the steam owing to radiation in the open air, and condensation of stopping and starting, thereby reducing the total efficiency to probably less than 4 per cent. (5) Less room is occupied by the motor than by the steam or hydraulic engines, and in the case of electric cranes, by leaving

* Abstract of paper read recently by Mr. A. H. Gibbings before the Hull and District Institution of Engineers and Naval Architects.

Digitized by Google

a clear space in front of the operator, the guidance and direction of the crane can be more readily and safely effected.

I will now briefly consider what advantages accrue from the use of electric cables in the place of steam-pipes: (1) The disadvantages of leaky steam joints are avoided. (2) Less space is occupied and greater facility in fixing is obtained. Steam-pipes are always more or less unsightly and inconvenient, and especially so when they pass through cabins and alley-ways. When they are carried on the surface of the deck, and have to be protected by large iron casings or coverings, they are a distinct source of danger to passengers and crew. On the other hand, electric cables can be carried the whole way on the underside of the deck or on the face of bulkheads, and the deck is thus left free and clear on the surface. (3) Electric cables can be bent to suit any angle. (4) No heat or any other unpleasant effects are experienced with electric cables. (5) No corrosion and no alternate expansion and contraction occurs, as with copper steam-pipes. (6) No loss of power, as with condensation of steam in pipes.

The loss of power in electric cables where the current does not exceed 500 amperes per square inch of section may be stated to be, on a 65-volt circuit, 1 per cent. of the total energy transmitted per 100 yards. This loss, moreover, is directly proportional to the length, which is hardly true of the loss of steam transmitted in pipes, such loss becoming greater in proportion after a certain distance from the boilers. A 1½in. copper steam-pipe covered to a thickness of 1in. all round with woollen felt, loses by radiation 73 thermal units per foot run per hour at a boiler steam pressure of 120lb. The loss, therefore, for 50ft. will be 3,650 thermal units or 1·5 h.p. per hour, which is a very large factor in the case of the small engines required for auxiliary machinery. It will be within the mark to estimate this power loss from 10 to 20 per cent. The economy, therefore, with the electric current is so marked and distinguished that there is no necessity for me to dwell longer on the subject, and I suppose it will readily be admitted by all that this advantage alone is a very prominent and important one. I have made only casual reference in this paper to the use of hydraulic power on board, because it is well known that this power is very wasteful and costly. Hydraulic machines take more pressure water when running unloaded than when working at their full load. They possess, moreover, several other disadvantages which are analogous to the drawbacks of steam power. In cold climates they are practically prohibitive, as the water could not be kept from freezing. I have endeavoured to place a few descriptions and comparisons before you this evening, more for the purpose of drawing attention to the subject generally than to prove facts. After all, and proverbially, the proof of the pudding is in the eating, and by actual test a satisfactory and ready comparison can always be made in specific instances.

THE ROYAL SOCIETY.

The anniversary meeting of the Royal Society was held on Friday at Burlington House.

The **President** (Lord Kelvin), in delivering the anniversary address, said that science had lost severely during the past year. In the list of Fellows deceased which had been read to them they had heard the names of Tyndall, Milnes Marshall, Van Beneden, Pengelly, Brown-Séquard, Romanes, Alder Wright, Helmholtz, Marignac, Topley, all well known to them as having been in their lives zealous and successful scientific investigators, who had largely contributed to the object for which the Royal Society worked—"the increase of natural knowledge."

A year ago, in his anniversary address, he called attention to Hertz's experimental demonstration of electric waves, which he found in working out an experimental problem originally proposed by Helmholtz to him when he was engaged in experimental researches in the Physical Institute of Berlin in 1879. An English translation by Jones of Hertz's book, describing his work on electric waves, dedicated "with gratitude" to Helmholtz, was published in England and America in December, 1893. On the first day of the new year the disciple died, and within the year the master followed him. Of the whole of Helmholtz's great and splendid work in physiology, physics, and mathematics, he doubted whether any one man might be qualified to speak with the power which knowledge and understanding could give; but they could all appreciate, to some degree, the vast services which he had rendered to biology by the application of his mathematical genius and highly-trained capacity for experimental research to physiological investigation. The president then reviewed some aspects of the work of Helmholtz, and dealt with administrative questions connected with the society.

The establishment of the Faraday-Davy Research Laboratory in connection with the Royal Institution was a splendid benefaction which science had gained during the past year through the untiring and grand generosity of Mr. Ludwig Mond. The Royal Society interested itself in all work contributing towards the object for which it was founded—the increase of natural knowledge; and while gratefully remembering the assistance so generously given to it in the humble but highly valuable work of cataloguing papers which described the results of scientific investigations already made, it hailed with delight this grand foundation of a practical laboratory, of which the purpose was not the teaching of scientific truths already discovered, but the conquering of fresh provinces from the great region of the unknown in nature.

The greatest scientific event of the past year was, to his mind, undoubtedly the discovery of a new constituent of our atmosphere. If anything could add to the interest which they must all feel in this startling discovery, it was the consideration of the way by which it was found. In his presidential address to Section A of the meeting of the British Association at Southampton in 1882, Lord Rayleigh, after calling attention to Prout's law, according to which the atomic weights of the chemical elements stand in simple relationship to that of hydrogen, said: "Some chemists have reprobated strongly the importation of *a priori* views into the consideration of the question, and maintain that the only numbers worthy of recognition are the immediate results of experiment. Others, more impressed by the argument that the close approximations to simple numbers cannot be merely fortuitous, and more alive to the inevitable imperfections of our measurements, consider that the experimental evidence against the simple numbers is of a very slender character, balanced, if not outweighed, by the *à priori* argument in favour of simplicity. The subject is eminently one for further experiment, and as it is now engaging the attention of chemists we may look forward to the settlement of the question by the present generation. The time has perhaps come when a redetermination of the densities of the principal gases may be desirable—an undertaking for which I have made some preparations."

The arduous work thus commenced in 1882 had been continued for 12 years by Rayleigh with unremitting perseverance. After 12 years of it, a first important part of the object—the determination of the atomic weight of oxygen with all possible accuracy—was attained by the comparison of Scott's determination of the ratio of the volumes of hydrogen and oxygen in the constitution of water with Rayleigh's determination of the ratio of the densities. The result was 15·82, which was almost 1 per cent. (0·87 per cent.) less than the 16 which it would be according to Prout's law. It was very slightly less (¼ per cent.) than Dittmar and Henderson's value, obtained by an investigation for which the Graham medal of the Glasgow Philosophical Society was awarded in 1890. Values not quite so small as these for the atomic weight of oxygen had been previously found by Cooke and Richards (15·869) and by Leduc (15·876). There could be no doubt whatever now that the true value was more than ¼ per cent. smaller than according to Prout's law, and that in all probability it agreed exceedingly closely with the results obtained by Rayleigh and Scott, and by Dittmar and Henderson. The question of Prout's law being thus so far set at rest, Rayleigh, persevering in the main object which he had promised in 1882, "a redetermination of the densities of the principal gases," attacked nitrogen resolutely, and stimulated by most disturbing and unexpected difficulties in the way of obtaining concordant results for the density of this gas as obtained from different sources, discovered that the gas obtained by taking vapour of water, carbonic acid, and oxygen from common air was denser by 1/230 than nitrogen obtained by chemical processes from nitric oxide or from nitrous oxide, or from ammonium nitrite, thereby rendering it probable that atmospheric air was a mixture of nitrogen and a small proportion of some unknown and heavier gas. Rayleigh and Ramsay, who happily joined in the work at this stage, had since succeeded in isolating the new gas, both by removing nitrogen from common air by Cavendish's old process of passing electric sparks through it, and taking away the nitrous compounds thus produced by alkaline liquor, and by absorption by metallic magnesium. Thus they had a fresh and most interesting verification of a statement which he took occasion to make in his presidential address to the British Association in 1871: "Accurate and minute measurement seems to the non-scientific imagination a less lofty and dignified work than looking for something new. But nearly all the grandest discoveries of science have been but the rewards of accurate measurement and patient, long continued labour in the minute sifting of numerical results." The investigation of the new gas was now being carried on vigorously.

A Royal medal was awarded to Prof. J. J. Thomson, who had distinguished himself in both mathematical and experimental fields of work. A Royal medal was awarded to Prof. Victor Horsley for his laborious and fruitful researches in physiology and pathology, and particularly for those relating to the functions of the nervous system and of the thyroid gland. Prof. Horsley had himself shown—and this was not the least of the merits which it was desired to recognise in the bestowal of the Royal medal—in how many instances the knowledge which was acquired by patient and skilful work in the laboratory might be made available for the saving of life, or the alleviation of human suffering. The Davy medal was awarded to Peter Theodor Cleve, professor of chemistry in the University of Upsala, for his services to chemical science during the last 30 years, and in particular for his long-continued and valuable researches on the chemistry of the rare earths. The Darwin medal was awarded to Thomas Henry Huxley. Of Mr. Huxley's general labours in biological and geological science he need say nothing there. They were known of all men, and the society showed its appreciation of their worth when it awarded to him the Copley medal in 1888. The present medal was a token of the value put by the society on the part of his scientific activity bearing more directly on the biological ideas with which the name of Charles Darwin would always be associated.

The medals having been presented, the society next proceeded to elect the officers and council for the ensuing year. The following is a list of those elected:

President, Lord Kelvin; treasurer, Sir John Evans; secretaries, Prof. Michael Foster, Lord Rayleigh; foreign secretary, Sir Joseph Lister; other members of the council, Andrew Ainslie

Common, William Crookes, Francis Darwin, Andrew Russell Forsyth, Sir Douglas Galton, Prof. Alexander Henry Green, Sir John Kirk, Prof. Horace Lamb. Prof. Edwin Ray Lankester, Prof. Alexander Macalister, Prof. John Henry Poynting, Prof. Arthur William Rücker, Osbert Salvin, Prof. J. S. Burden Sanderson, Thomas Edward Thorpe, William Henry White.

The anniversary banquet of the society was held in the evening at the Whitehall Rooms of the Hôtel Métropole.—*The Times.*

GREAT NORTHERN TELEGRAPH COMPANY.*

If the science of stock-splitting makes slow progress in its native country, it begins to find favour abroad. An interesting application of it has been mooted among the shareholders of the Great Northern Telegraph Company, which owns one of the largest of the Eastern cable systems. It is a Danish corporation, administered in Copenhagen, but the bulk of its shareholders are in London and Paris. Its shares have long been honourably known on our official list, where they now stand at a premium of fully 100 per cent. Their par value is £10, but they can no longer be purchased under £21, and only in small lots at that. The dividends actually paid do not represent a very large yield on their market price. It is the undivided earnings which go to swell the reserve fund and to pay off debentures that account for the high premium. Many of the shareholders, the French ones in particular, consider that the future has been pretty well provided for by a reserve which exceeds one-half of the Company's total capital. Being so large, it might now, they think, grow fast enough with smaller additions than from £60,000 to £80,000 a year. Recently this argument has acquired greater force and plausibility from the healthy expansion of the Company's revenue.

The Great Northern Telegraph Company has a peculiar way of dividing its surplus profits, and this is another matter which a section of the shareholders would fain have simplified. The share warrants have a set of three coupons attached to them for each year. Two are for interest at the rate of 5 per cent. per annum, which is paid in January and July. The third is a surplus coupon, payable in April, which varies in amount according as the year's profits exceed 5 per cent. From 1890 to 1893 the surplus distribution was 7s. 2d. per share, making a total of 17s. 2d. But this was only two-thirds of the profits actually earned, the other third, amounting to £83,000 out of a total of £250,654, having been carried to reserve—a sum equal to another 11s. per share of dividend. The increased earnings up to the end of October—about £8,000—represent rather more than 1s. per share, and, without reckoning any further gain in November and December, they ensure a moderate addition to the surplus divisible next April. The total dividend on the present basis should be 18s. per share, but if any concession were to be made to those shareholders who consider the reserve unduly favoured, a reduction of its annual increment by £15,000 a year—a mere trifle out of fully £80,000—would raise the dividend to a round 20s. per share, or 10 per cent. on their par value.

At the same time it is suggested that the shares might be made more negotiable if the interest coupons and the surplus coupons were separated. This would be equivalent to splitting the shares into 5 per cent. preferences and deferred, the latter starting with a present surplus of 3 per cent., which might by a very moderate restriction of the reserve be at once raised to 5 per cent. The existing certificates, which carry all three coupons, could be called in by the Company and split certificates issued in place of them, one with the interest coupons and the other with the surplus coupons. The nominal amount of each would be a million and a half sterling, the same as the existing capital; but in place of an unwieldy share forced up to over 100 per cent. premium, we should have a preference half standing about 13, and a deferred half ranging from 10 to 12, according to the surplus distribution. That this would be not only a more marketable, but a sounder capitalisation than the present, may be proved from the example of English cable companies operating in the same part of the world as the Great Northern, and under similar conditions.

The Great Northern Telegraph Company, with only one-fourth of the capital of the Eastern Telegraph Company, earned about one-half its revenue, both in gross and net. The former was for the year 1893 £352,975, and the latter about £270,000. The strong point of the Great Northern is its light capitalisation—the result of the liberal expenditure for improvements and extensions made out of revenue. It has to pay charges on only £1,700,000, while the Eastern has to pay on over £6,000,000. Its gross annual earnings are equal to nearly 25 per cent., and its net earnings to more than 14¼ per cent. on its whole capital, debentures included. The gross earnings of the Eastern Company represent only 12 per cent. on the total capital, and its net earnings barely 5¾ per cent. The financial features of the two companies exhibit a very instructive comparison for shareholders who care to know where their dividends come from, and how they are capitalised. Fair allowance being made for its larger earning power, both in relation to capital and to cable mileage, Great Northern shares, if split, should find as much appreciation in the market as corresponding shares of the Eastern.

Whatever may come out of the splitting movement, Great Northern Telegraph dividends have a promising future before them.

* Abstract of article in *Financial Times*, December 1, 1894.

GENERATION OF ELECTRICITY AT COLLIERIES.

At the present time it appears, Mr. Walter J. May writes in the *Colliery Guardian*, as if an important and cheap mode of generating current has been quite overlooked. Where the Semet-Solvay coking system is adopted it would also appear that the generation of current would be more or less a cheap matter, as surplus gas is always to hand, which could be used to produce current at a much less cost than it can be produced by steam power at town works. The conveyance of high-tension current is not all an insuperable difficulty, and overhead cables would be possible in most instances until near the town where it was intended for use, and then, of course, it would be carried in underground mains to the distributing centres.

At the town where the writer resides the electric light has been installed by the Corporation, the capital expenditure being £26,000; 1,700 tons of slack is the year's allowance for the two boilers, two contracts of 800 and 900 tons respectively having been advertised, the average price being 12s. per ton plus 1s. 3d. per ton for cartage, making a total cost for fuel of £1 126. At the collieries the value of the coal used would be not more than 4s. per ton, and thus the difference in the cost of fuel alone would be £786. Besides this, it must again be considered that a colliery using enough coal to produce 10 times the current produced at the works to which reference is made, only the same staff of men employed would be practically wanted. Even on the score of fuel and labour costs alone it would pay to produce the current where the fuel is raised, and probably the cost of cables for the conveyance of current would be less than the capital which has to be invested in local generating stations.

Beyond this, it has to be considered that at most coalpits there is a more or less plentiful supply of dirty fuel which is practically unsaleable, but which would make fairly good boiler fuel if the boilers were in sufficient number to allow of their being run without driving, thus again reducing the cost of production of current. Still, too much stress must not be placed on this dirty fuel, as every pit is not alike, and it is well to take costs from general values rather than from special ones. Beyond the current for lighting, there is a probable demand for more or less current for motor purposes during that part of the day when light is not required, and thus the boilers would be in active work at all times instead of being banked down for part of each day, and there would be no fuel wasted as a consequence, whereas at local stations the boilers are not in use for part of each day. Combined with the lower cost of the fuel, this continuous working would tend to economy in the cost of the production of the current, and with a well-arranged generating plant of a sufficient size the cost per Board of Trade unit should be under 2d. at the generating station.

At cokeworks two products could bo sent out—coke and electric current, the gas being stored and used to actuate gas-engines. In this we should have even better results than with steam boilers and engines, as there would be no loss even if the current was only used for a portion of each 24 hours, as the gas would be used only when the engines were running. Beyond the ordinary gas, the breeze could be converted into gas of good power for gas-engines, and the actual cost of power would be much smaller than where steam is used as the primary power. In fact, gas-engines are too little used for the motive power in electric lighting stations, and the result is often to put several pence per unit on the current, particularly in small places.

The following comparison of the amount of 16-candle light obtainable in London for a penny may be not only instructive, but also useful in regard to the electric lighting question, because it shows that unless the electric current is much reduced in cost it will never displace gas:

	Hours.
Gas with Welsbach burners	22·2
Incandescent electric lamps, current generated by gas-engine and Dowson gas	10·6
Petroleum with duplex burner	8·6
Petroleum with good single-wick burner	8·0
Gas with argand burner	6·4
Gas with fishtail burner	4·7
Incandescent electric lamp with current from town mains...	2·2

Assuming that these figures are approximately correct, it will be seen that the cost of current must be very considerably reduced in many places before it can compete with gas on anything like equal terms, and it appears to the writer that it would be chiefly through the production of the current at mines, or in close contiguity to mines with fuel of small value, that this low cost can be obtained.

REFUSE DESTRUCTORS AND ELECTRIC LIGHTING AT WESTON-SUPER-MARE.

REPORT BY THE CONSULTING ENGINEER.

We have been favoured with a copy of a report prepared by Mr. Francis H. Medhurst, M.I.E E, for the Weston-super-Mare Local Board, who received and passed it on Wednesday. The report, from which the following is extracted, deals with the questions of refuse destruction, electric lighting, and electric tramways. The further consideration of the report has been deferred for the new district council.

Refuse Destruction.

The report first draws attention to the fact that the only satis-

Digitized by Google

factory method of disposing of town's refuse is by the operation of a refuse destructor. Special stress is laid on the point that a destructor must, first, be considered as a sanitary apparatus, and, secondly, as an auxiliary to an electric lighting undertaking. The report weighs the merits and describes the characteristics of the two essential types of refuse destructors, and it recommends for adoption the Horsfall destructor, mainly on account of the high temperature (2,000deg. F.) to which the fumes from the drying refuse and the half-distilled products of combustion are subjected.

Mr. Nettleton, the Local Board's engineer, has given Mr. Medhurst's figures showing approximately the amount of refuse collected at Weston during the winter and summer months. Taking these figures as a basis, the Horsfall Company have offered to erect at Weston three of their refuse furnaces in one battery, and to supply all the steam that will, in the engineer's opinion, be required for some years to come for electric lighting purposes for £460 per annum. The consulting engineer recommends the Local Board to accept this offer. The cost of raising the same amount of steam using coal as a fuel would in all probability work out at £530 per annum, showing a direct saving of £72 per annum if a refuse destructor be erected and worked in conjunction with the electricity supply works. If a refuse destructor be erected at Weston, but be kept absolutely distinct from the electric lighting undertaking, then it is shown that the combined cost of raising steam on the one hand, and of working the destructor on the other, would be about £850 per annum—*i.e.*, more than £300 per annum more than would be the case if the scheme recommended in the report be carried out.

Electric Lighting.

In order to ascertain the amount of support that would be given to an electric lighting undertaking in the hands of the Local Board, one of his assistants made a canvass of the district. The result was satisfactory, inasmuch as the equivalent of 4,500 lights of 10 c.p. were promised. The engineer recommends that mains for private supply should at once be laid in the following streets—namely, High-street, Regent-street, Kewstoke-road, Meadow-street, Magdala-buildings, Waterloo-street, and Orchard-street. The only public lighting recommended for the present is that along the sea-front from the sanatorium to Anchor Head. It is pointed out that the present cost of lighting the sea-front is £190. 5s. 2d, per annum, and the total candle-power of all the lights burning simultaneously is equal to about 1,360 candles. If the recommendations of the report be carried out, the cost of lighting the sea-front will be increased to about £300, and the total light emitted simultaneously will be increased to 34,000 candles. The site recommended is one already belonging to the Local Board, situate in Uphill Drove-road, close to the statutory hospital. It is pointed out that there is ample room here for the erection of the dust destructor as well as of the electricity works.

The system recommended is the high-pressure alternating-current system, with transformers in sub-stations, and a low-pressure network of mains for private supply. The current will be generated at a pressure of 2,000 volts at the generating station, and will be conveyed by means of insulated stranded copper cables drawn through cast-iron pipes with drawing-in boxes at intervals of about 100 yards apart along Severn-road and the esplanade to the corner of Regent-street, down Regent-street to the corner of Regent-street and High-street, down High-street to the post office. Transformers, fixed in underground vaults or sub-stations will tap the high-pressure mains at the corner of High-street and Regent-street, and at the post office. The low-pressure mains will likewise consist of insulated stranded copper cables drawn into cast-iron pipes, with junction-boxes at intervals of about 50 yards apart. The low-pressure mains will be laid in the streets previously mentioned. The public lighting cables will be drawn into 4in. cast-iron pipes, and there will be a junction-box opposite each lamp-post.

The machinery at the generating station will consist of one water-tube boiler of 150 actual horse-power, and the dust destructor boilers one second 150-h.p. boiler. The result will be that, whether the dust destructor be erected or not, there will be a spare boiler of 150 actual horse-power. There will also be two compound steam alternators of 130 b.h.p. each, one being spare, and three Ferranti rectifiers to transform the ordinary alternating current into an undulating or practically direct current. In addition, the buildings will contain the necessary feed pumps, switchboard, etc., and, lastly, if the electric lighting undertaking be carried out apart from, and not in conjunction with, the dust destructor, there will be a 20-b.h.p. gas-engine, driving its alternator by means of a belt. The effect of the gas-engine will be to reduce the working expenses to a minimum by enabling the boilers to be banked up, and the stoker sent away during the daytime or time of light load. Of course, if the refuse destructor be in operation, there is no advantage in making the capital expenditure to pay for a gas-engine, for probably the minimum amount of firing of the destructor will produce more heat than will be required for the maximum demand for steam during 13 to 16 hours out of the 24.

Capital Expenditure.

The capital expenditure, if the present scheme be carried out, is estimated as follows: plant and buildings, £8,466; pipes and trenching, £3,944; cables, £2,547; and engineering charges and contingencies, £1,043; being a total of £1,600. If a refuse destructor be not erected it is estimated that the cost will be increased to £17,000.

Statistics prove that the average price to be expected per lamp of 10 c.p. per annum is 10s. Therefore the total revenue from 4,500 lamps will be £2,250. The Local Board can borrow the requisite capital at 3 per cent., whilst 2½ per cent. must be set aside annually to form a redemption fund for liquidation of the loan. We have, then, the following results: Revenue—4,500 lights, £2,250; present cost of esplanade lighting, £190; and meter rents, £100; or a total of £2,540. Working expenses—cost of steam production, £460; engineer, £200; wages, £416; interest and redemption 5½ per cent. on £16,000, £880; and upkeep, renewals, and depreciation, £300; being a total of £2,256.

Thus it will be seen that the scheme recommended for adoption is not only likely to be self-supporting from the very commencement, but will in all probability actually earn a profit of over £250 per annum, which, as the report suggests, might be used for the reduction of the local rates. It is also stated that as the demand for electric lighting increases, the profits from the undertaking will compare still more favourably with the expenditure.

Electric Tramways.

The various systems of electric traction are described, and the method which is said would probably have to be adopted at Weston is the conduit system. The capital cost is estimated at £14,500 for a tramway from the sanatorium to the pier, with a branch along Regent-street to the railway station. It is assumed that a 15-minute service would be necessary along the sea-front and a half-hour service along the branch line.

Calculations are made which show that the probable gross earnings would not exceed £990 per annum, owing to the fact that the tramway would only be used, at the most, for five months out of the twelve. The loss on the tramway undertaking is estimated at from £450 to £600 per annum, and the engineer is, therefore, unable to recommend the Local Board to adopt an electric tramway at Weston on economical grounds, though he recognises that it would in many respects be a great convenience to visitors and to the inhabitants along the sea-front.

Conclusions.

The following are the concluding remarks of the report, expressed in the engineer's own words. He says: "I think the only conclusions to be drawn from the above considerations are (1) that electric tramways will not pay at Weston; (2) an electricity supply undertaking will pay a profit if carried out quite independently, and will provide a brilliant illumination along the sea-front, which is of itself likely to prove a great attraction to Weston; (3) if a refuse destructor be erected, and if it be worked in conjunction with the electricity supply works, the paying capacity of the latter will be enhanced, whilst Weston will be supplied with a much-needed sanitary reform—a fact of great importance to every town, and especially to a town that is essentially a health resort."

ELECTRIC LIGHTING AT HARROW.

It is satisfactory to note that the scheme for the establishment of an electric light station at Harrow, to which we have referred from time to time, is progressing, a tender having been provisionally accepted by the Local Board, as mentioned in our last issue. After considering the various tenders received, the Electric Lighting Committee of the Local Board drew up a report, of which the following is an abstract:

The committee have opened and considered, with the assistance of the engineer, Mr. W. C. C. Hawtayne, tenders from the British Thomson-Houston, Limited, the Brush Electrical Engineering Company, Limited, Messrs. Crompton and Co., Limited, the Electric Construction Company, Limited, Messrs. John Fowler and Co., Limited, the India Rubber, Gutta Percha, and Telegraph Works Company, Limited, Messrs. Siemens Bros. and Co., Limited, and Messrs. J. G. Statter and Co., Limited. Specifications were also sent to Messrs. S. Z. de Ferranti, Limited, and Messrs. Mather and Platt, Limited, but no tenders were received from them. All the tenders received, except one, are as a whole below the estimate furnished to the Board by Mr. Hawtayne.

After dealing with the objections raised to the scheme, the report continues: The most important proof of the soundness of the scheme is to be found in the actual tenders which the Board have received. The tenders were for the full equipment of the undertaking exclusive of buildings and trenching, and for working the station year by year. The contractors were asked to give alternative tenders for erecting the station either at the Harrow Pond and Gardens site or at the Board's depôt at Bessborough-road. It was thought that the buildings should be erected by builders in Harrow, but tenders could not be invited until the requirements of the contractors as to floor space and other details were known, and it was also thought that labour in the district should be employed for making the trenches for the mains. After a careful examination of the tenders, that of Messrs. Crompton and Co., Limited, appeared the most suitable, but the Board propose that they should themselves carry out such part of the work as relates to mains for private lighting, in which respect they believe it may be possible to save from £500 to £1,000 by a modification of the system proposed. Without, however, taking this branch of the work from Messrs. Crompton and Co.'s tender, their figures amount to £8,139. 15s., to which must be added about £1,000 for trenching and transformers, bringing the total amount to £9,139, as against Mr. Hawtayne's estimate of £9,300. Messrs. Crompton and Co.'s tender is based on the assumption that the station will be erected at the depôt, which the Board have decided is the preferable site. About £150 would have to be added to either amount for purchase of meters. Messrs. Crompton and Co.'s tender for working the lighting varies with the number of

of

Digitized by Google

units consumed each year, and is as follows: If the output reaches

50,000	units the cost would be	£1,331*	equal to	6¼d. per unit
60,000	,,	1,411	,,	5$\frac{13}{16}$,,
80,000	,,	1,541	,,	4¾ ,,
100,000	,,	1,686	,,	4$\frac{11}{16}$,,
120,000	,,	1,900	,,	3¾ ,,
150,000	,,	1,975	,,	3$\frac{3}{16}$,,

Mr. Hawtayne estimated that when all the lamps were taken up there would be an output of about 115,000 units, and his estimate for working expenses was at the rate of 4¼d. per unit. Messrs. Crompton and Co. furnish the following figures for the yearly working of the station according to the number of lamps estimated for by Mr. Hawtayne:

Output of Station.

3,400 lamps in masters' houses and private houses, each consuming 18 units per annum	61,200 units.		
600 lamps in school buildings, each consuming seven units per annum (modified from Mr. Hawtayne's original estimate of 10,800 units)	4,200 ,,		
		65,400 units.	
Street-lighting		43,000 ,,	
		108,400 ,,	

Revenue.

65,400 units at 8d. (private lighting)	£2,180	0	0			
Street-lighting (credit price paid for gas lighting)	550	0	0			
Meter rents, say	20	0	0			
				2,750	0	0

Working Cost.

Messrs. Crompton and Co. guarantee that this shall not exceed for the above output	1,736	0	0			
Add expenses of office and collection	100	0	0			
				1,836	0	0
Balance available				914	0	0
Repayment of instalments and interest on capital expenditure 6 per cent. on, say, £12,000				720	0	0
Leaving a yearly profit of				£194	0	0

The committee are aware that the gas company do not give discount to the consumers on punctual payment, but they would recommend the Board to adopt that course if they supply the electric light. It would amount, at 5 per cent., to £109. The Board could well afford to do this, especially if they worked the station themselves and so saved the contractor's profit. Mr. Hawtayne's figures being so remarkably confirmed by the experience of working in large and small towns and the actual tenders received, the committee think it would be a misfortune if the lighting of Harrow by electricity were to pass out of the Board's hands. It seems to the committee that the Board would be able at no distant date to reduce the price at which they would supply the light, and that if they handed the scheme over to a company they would not be doing their duty as representatives of the ratepayers, even if they succeeded in obtaining repayment of the money already spent in obtaining the provisional order and the information they have collected. While the concern is in their hands every advantage obtained would go directly to the ratepayers, and their interests would be consulted. A company would naturally look after its own interests before those of the place, and if the Board wished hereafter to acquire the concern they would have to pay heavily for it.

LEGAL INTELLIGENCE.

ALABASTER AND OTHERS v. HARNESS.

In the Court of Appeal on Tuesday and Wednesday, before the Master of the Rolls and Lords Justices Lopes and Rigby, the appeal of the defendant in this case was heard and decided. It was an appeal by the defendant in an action brought by the proprietors of the *Electrical Review* against Mr. Harness, who had been connected with the "Medical Battery Company," to recover damages for "maintenance." The case for the plaintiffs was that the defendant had instigated Dr. Tibbits to bring an unfounded action for libel against them in respect of an article that had appeared in their journal reflecting upon Dr. Tibbits, the present defendant, and the "Medical Battery Company." The verdict in the case was in favour of the present plaintiffs, on the ground that the alleged libel was a privileged criticism, but the plaintiffs were unable to obtain their costs, amounting to £435, from Dr. Tibbits. The plaintiffs thereupon brought the present action against the defendant, Mr. Harness, to obtain payment of the costs in the first action, on the ground that the defendant had instigated Dr. Tibbits to bring the action. At the trial before Mr. Justice Hawkins, the defendant contended that he had a common interest with Dr. Tibbits in bringing the first action, and that therefore no action for maintenance would lie against him in respect of anything that he might have done in the way of promoting the litigation. The learned Judge, however, upon further consideration, held that the defendant had no common interest in the action brought by Dr. Tibbits, and that therefore he was bound to pay the plaintiffs the costs they had incurred in the action. The defendant appealed. Mr. Jelf, Q.C., and Mr. F. Dodd appeared for the defendant.

The respondents were not called upon.

Their **Lordships** held that the attack in the article in question formed no part whatever of the ground of Dr. Tibbits's action, and that therefore the defendant, who had undoubtedly induced Dr. Tibbits to bring that action, must pay the amount of the costs incurred by the present plaintiffs in defending the action.

Judgment was given accordingly.

LONDON ELECTRIC SUPPLY v. CRAWFORD.

A case of considerable importance to electric supply companies, and one which should serve as a warning to the public, was decided in the Law Courts on Wednesday. The action was brought by the London Electric Supply Corporation against Mr. Crawford, of the Lytton Club, to recover £20, damages claimed for alleged breach of agreement.

The plaintiffs' case was that the defendant had entered into an agreement with them for one year for the supply of current to the equivalent of 150 incandescent lamps, and that he had cancelled the agreement, although the plantiffs had been put to expense in getting out plans, etc., in connection with the supply. The plaintiffs brought the claim as a test case. The defendant consented to a judgment of £15 and costs.

This case shows plainly that the agreements entered into between supply companies and consumers are valid, and this fact should be borne in mind by the public.

CLAIM FOR COMMISSION.

The case of South *v.* Perry and Co. was tried in the Westminster County Court on Friday before his Honour Judge Lumley Smith, Q.C. It was an action by the plaintiff, who is an electrical engineer, to recover from the defendants, who are dealers in electric light fittings, the sum of £7. 10s., being commission at the rate of 10 per cent. on a quantity of electric light fittings supplied to the plaintiff's customer at a house in Grafton-street, Bond street. The evidence of the plaintiff's witness went to show that they were employed to fit up the electric light at the house of a Mr. Johnson in Grafton-street, and as there was some difficulty as to the choice of the fittings, it was agreed that the plaintiff was to get them. In pursuance of that arrangement, several firms were negotiated with, and ultimately the goods were obtained from the defendants on the distinct understanding that the plaintiff was to have a commission of 10 per cent. After they were fixed up, however, the customer did not quite approve of them, and he was given the address of the defendant firm, in order that he might choose for himself. The result of that was that Mr. Johnson got into communication with the defendant firm and purchased a new set of fittings altogether at a cost of £75, and the agreed commission of 10 per cent. on the order was now claimed, but for some reason or other the defendant objected to pay.

For the defence **Mr. Bartlett** was called, and said he was the sole proprietor of the firm of Perry and Co, carrying on business at Albemarle-street, Bond-street. He did not recognise the plaintiff's claim in this action because he considered that the sale was brought about by an interview which he personally had with Mr. Johnson. The latter gentleman called at his place of business and chose an expensive pendant, and gave instructions for it to be fixed up in his dining-room. When witness went to the house he at once recognised that the pendant already existing in the room was an iron one which had been previously purchased by the plaintiff, but considered by Mr. Johnson to be unsuited to the room.

His **Honour** said the whole question was as to whether or not Mr. Johnson gave this order to the defendant in consequence of the introduction of Mr. South. He was of opinion that he did, and therefore judgment would be for the plaintiff for commission at the rate of 10 per cent. on the amount of the order and costs.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Madrid.—Tenders are invited by December 20 by the Ministère d'Outre Mer, Madrid, and by the General Government of Havana, for the construction of a telephone system in the island of Santa Clara.

London, N.—The tenders for the Great Northern Railway Company for telegraph and electric lighting material, referred to in our last issue, must be delivered at King's Cross by 10 a.m. to-morrow (Saturday) morning.

Coventry.—The Corporation invite tenders, from manufacturers, for electricity meters. Particulars may be obtained at the office of Mr. Robert Hammond, the consulting electrical engineer, Ormond House, Great Trinity-lane, London, E.C. Tenders to be delivered to Mr. Lewis Beard, town clerk, by Wednesday, December 12.

Enniscorthy (Ireland).—Tenders are invited for providing the Enniscorthy District Lunatic Asylum with internal telephonic communication, about 13 stations being required. Tenders will be considered by the Board on December 12, and should be sent,

* This and the following sums do not include rent, rates, and taxes, but there are allowed sums varying from £100 to £130 for office and collection expenses, which if carried out by the Board may be deducted.

Digitized by Google

addressed to the chairman, so as to reach the asylum by 6 p.m. on December 11. Further particulars can be obtained from the resident medical superintendent.

Blyth.—The Cowpen District Local Board (Blyth, Northumberland) invite tenders for the efficient lighting, by electricity or otherwise, of the lighting area within their district for a period of seven or ten years respectively, commencing from August 15, 1895. A plan of the district can be seen and further information obtained at the surveyor's office, Commercial-buildings, Waterloo, Blyth. Tenders, endorsed "Lighting," to be sent to Mr. Robt. T. Guthrie, clerk to the Board, not later than December 20.

Swindon.—Tenders are invited for lighting works, for the Swindon New Town Local Board as follows: (1) supply of gas, oil, or other light to, and lighting and cleaning of all lamps within the district of Swindon New Town for one year commencing January 1; (2) supply of gas, oil, or other light, only for all lamps within the district for one year commencing January 1; (3) lighting and cleaning all lamps within the district for one year commencing January 1. Tenders by 10th inst. For further particulars apply to Mr. Henry Kinneir, clerk, Public Offices, Swindon.

Hanley.—The Corporation of Hanley are prepared to receive tenders for the supply and erection of the following plant: Contract No. 10—extension of engine-house plant, including 200-kilowatt alternator, 25-kilowatt alternator, and 20-kilowatt exciter, each separately driven by a compound steam-engine, with all necessary steam and exhaust pipes, valves, switchboard, and appurtenances; Contract No. 11—extension of condensing plant, consisting of circulating pump, air-pump, boiler pump, surface condenser, with all necessary pipes and appurtenances. The drawings can be inspected, and specifications, prepared by Mr. G. H. Cottam, Corporation electrical engineer, together with general conditions and forms of tender, can be obtained at the offices of Mr. Joseph Lobley, Town Hall, Hanley, on payment of 5s. Tenders are to be delivered to Mr. Arthur Challinor, town clerk, on or before January 5, 1895. The Corporation do not bind themselves to accept the lowest or any tender.

RESULTS OF TENDERS.

Sunderland.—The Town Hall Committee have accepted the following tenders: Messrs. Reed, Ferens, and Co., for wiring the Town Hall; and Messrs. Crompton and Co., for altering the gas fittings.

London, W.C.—For carrying out repairs at the Covent Garden latrines, including the installation of electric light, for the Strand Board of Works, the tender of Mr. G. Jennings, at £1,440 has been accepted.

Bournemouth.—The following four tenders have been received for the electric lighting of the Punshon Memorial Wesleyan Chapel:

W. Haydon	£99 10 0
W. H. Aish	96 16 0
Roger Dawson	87 10 0
Bacon and Curtis	84 0 0

The last has been accepted.

Harrow.—The following tenders have been received by the Local Board (and are referred to in a report given in another column) for establishing a central electric light station: British Thomson-Houston, Limited; Brush Electrical Engineering Company, Limited; Crompton and Co., Limited; Electric Construction Company, Limited; J. Fowler and Co., Limited; India Rubber, Gutta Percha, and Telegraph Works Company, Limited; Siemens Bros. and Co., Limited; J. G. Statter and Co., Limited. As mentioned in our "Business Notes" last week, the Local Board have provisionally accepted the tender of Messrs. Crompton and Co.

BUSINESS NOTES.

Radcliffe.—The Local Board intend to charge 8d. per unit for current.

Kendal.—The Town Council are enquiring into the subject of electric lighting.

Burnley.—The equivalent of 6,000 8-c.p. lamps are now connected to the mains.

Buckland.—Messrs. Mannering's mills at Buckland, Kent, are to be lighted electrically.

Newport (Isle of Wight).—The Hermite purification of sewage system is being used here.

Chelmsford.—An extra electric light has been placed in the centre of the Maltese-road.

Folkestone.—Mr. Webster has installed the electric light in Maestrani's refreshment-room.

Wishaw.—The Town Commissioners intend to apply for a provisional electric lighting order.

Great Northern Telegraph Company.—For the month of November the receipts were £26,400.

Stanton.—Negotiations are on foot for having Stanton lighted electrically from the Stanton-lane Colliery.

Bacup.—The Town Council are considering the advisability of adopting the electric light for the Maden public baths.

Passage.—The directors of the Passage Docks have bought the electric lighting plant lately used at Donnybrook Fair.

Dewsbury.—The Board of Guardians propose to introduce the electric light into the Dewsbury and District Infirmary.

Commercial Cable Company.—The Board has declared a quarterly dividend of 1¾ per cent., payable on January 2.

Wolverhampton.—The building for the central electric light station is practically completed, and the plant is all down.

Isle of Man.—Mr. Tennant, of King Orrey, has carried out an electric light installation at St. George's Woollen Mill, Laxey Glen.

Cuba Submarine Telegraph Company.—For the month of November the receipts were £100 more than for the corresponding period.

Eastern Telegraph Company.—The receipts for the month of November were £64,095, as against £60,995 for the corresponding period.

Nottingham.—Four 4,000-c.p. Brockie-Pell arc lamps have been placed in the Market-place. They take the place of nine large gas lamps.

Croydon.—A temporary electric light installation is to be placed in the new municipal buildings until the public supply is ready.

London, W.C.—The London County Council have authorised the expenditure of £30 for the purchase of electric lamps for the central offices.

Halifax.—The machine-room at the central electric light station is virtually finished, and the plant will shortly be running for testing purposes.

Direct Spanish Telegraph Company.—For the month of November the receipts were £1,733, as against £2,442 for the corresponding period.

Huddersfield.—The electric light is now installed in the infirmary and in the Theatre Royal, current being taken from the Corporation mains.

Yarmouth.—A company is applying for powers to construct tramways in Yarmouth, and to use animal power or mechanical power other than steam.

St. Helens.—A sub-committee of the Gas Committee of the Town Council has been appointed to enquire into the question of introducing the electric light.

Eastern Extension Telegraph Company.—For the month of November the receipts show an increase of £2,817 as compared with the corresponding period.

Wantage.—Messrs. Robinson and Auden, Limited, have lighted their works electrically. The engine is of their own make, and the dynamo by Mr. Newton, of Taunton.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 2nd inst. amounted to £902, as compared with £565 in the corresponding week of last year.

St. Austell.—A new building has been erected for the Young Men's Christian Association which is lighted throughout electrically. The installation has been carried out by Messrs. Veale and Co., St. Austell.

Bury.—Arc and incandescent lamps have been installed in Messrs. Milnes Bros.' works at Lumn, near Bury, the work having been carried out under the superintendence of Mr. W. H. Campbell, Tottington.

Isonomy Patentees Co-operative Trust, Limited.—This Company has been registered with a capital of £500 to acquire, work, or otherwise utilise British and foreign patents of practical value and public importance.

Ipswich.—Colonel Ducat, R.E., one of the inspectors of the Local Government Board, has sat to enquire into an application by the Ipswich Corporation for sanction to a loan of £2,000 for an experimental trial of the Hermite system of sewage purification.

Worcester.—The Town Council are applying to the Local Government Board for sanction to borrow £18,030 for electric lighting purposes, in addition to £1,000 authorised in October, and also to borrow £1,200 for wiring the Guildhall and Public Hall.

Clifton.—Sixty-four 16-c.p. incandescent lamps are being installed by Messrs. Crompton at Clifton College, and they are also wiring three houses connected with the college. The work is being carried out under the superintendence of Mr. H. T. Sully, of Bristol.

Stock Exchange Notice.—An application has been made to the Stock Exchange Committee to appoint a special settling day in Willans and Robinson, Limited—20,459 6 per cent. cumulative preference shares, Nos. 30,001 to 50,459, and 19,375 ordinary shares, Nos. 1 to 19,375.

Ayr.—The committee of the Town Council, which, as we mentioned last week, was appointed for the purpose, have purchased a site for the electric light works. The ground secured is near the head of Mill-street, and runs from the street to the river. The purchase price is £1,550.

Blackpool.—It is stated that the applications for shares in the new Blackpool, St. Annes, and Lytham tramways have not been sufficiently large to warrant the directors in proceeding to allotment. The project, however, is not to be abandoned, for a syndicate of gentlemen have taken the work in hand.

Brentford.—Mr. Sarbury, London-wall, has asked the Local Board the terms upon which they would grant a concession for lighting the district electrically. The Board have returned an evasive answer, to the effect that sufficient details were not before them to enable them to come at present to a decision.

City and South London Railway.—The receipts of the Company for the week ended December 2 were £928, against £905 for the corresponding week of 1893, or an increase of £23. The total receipts for the current period of the present half-year amount to

Digitized by Google

£19,576, as against £18,275 in the corresponding period of 1893, an increase of £1,301.

Liverpool.—The special committee recently appointed by the Council to deal with the lighting of the city are understood to be considering a proposal for the adoption of electricity as a means of lighting the principal thoroughfares, and have had a conference on the subject with the directors of the Liverpool Electric Supply Company, Limited.

Barnet.—Mr. J. G. Walker, butcher, of High-street, Barnet, has had the whole of his premises fitted up with the incandescent light, from Messrs. Swain's installation, under the superintendence of Mr. Holt. The outside lights consist of four 25-c.p. lamps. He has also three 16-c.p. in the shop, five 8-c.p. and two 16-c.p. lamps for his premises at the rear, and 8-c.p. lamps for the various rooms in the house.

Fareham.—The Local Board have made application to the Local Government Board for permission to borrow £7,000 for electric lighting purposes (including the purchase of the undertaking of the Fareham Electric Lighting Company). A public enquiry will be held by Colonel J. T. Marsh, R.E., a Local Government Board inspector, at the offices of the Local Board to-day (Friday).

Salford.—In reply to a question by Mr. Alderman Dickins, Mr. Holland, chairman of the Gas Committee of the Town Council, has stated that the householders of Salford need not expect to have the electric light this winter. The contractors appeared to be hopelessly behind their time. The committee had decided to sell the electric light at 7d. per unit., which was 1d. less than was charged at Manchester.

Change of Address.—The Epstein Electric Accumulator Company, Limited, have removed from 21A, Blythe-road, West Kensington, to 215, Gresham House, Old Broad-street, E.C. Mr. Frederick Nell, of 26, Mark-lane, notifies that on and after the 12th inst. his address will be 97, Queen Victoria-street, E.C, where he has taken showrooms and offices for an exhibition of the "Victor" turbine and pumping machinery.

Peckham.—Additions are being made to the premises of Messrs. Jones and Higgins at the junction of Rye-lane and High-street, Peckham. The electric light will be adopted in parts of the premises, and the electrical plant has been supplied by Messrs. J. Slater and Co., of Holborn. An Adamson steam-boiler is employed. A well has been sunk at the rear of the premises, and the water will be pumped by means of a electrically-driven pump.

Dan Rylands, Limited.—The sixth annual general meeting of this Company was held at the works at Stairfoot, near Barnsley, on Monday. The report submitted stated that the accounts for the year ending August 31 show a loss of £1,159 after providing interest on the debenture debt and loans. Owing to adverse weather in the summer, the coal strike, and the consequent bad trade in the colliery districts, a large loss was sustained. The report and accounts were adopted.

Newcastle.—The Newcastle and District Electric Lighting Company, Limited, Forth Banks, have entered into a contract with the Co-operative Wholesale Society for the supply of the electrical current required for the lighting of the latter firm's large new warehouse now in course of erection in Blandford-street. This will be the largest electric lighting installation in Newcastle, being equal to about 2,500 10-c.p. incandescent lamps. The Board of Guardians intend to light the workhouse by electricity.

Rugby.—Messrs. Willans and Robinson have just acquired 30 acres of land in Newbold-road, Rugby, close to the railway, and are preparing to erect works on a large scale for the construction of stationary engines, their works at Thames Ditton having become too small for their requirements. The works, which will have a frontage to the London and North-Western Railway of about 1,000ft., will cover about 20 acres of land, and it is estimated, when in full swing, will provide employment for about 300 men.

Aberdeen.— The Gas and Electric Lighting Committee of Aberdeen Town Council have opened the tenders, seven in number, for the work of extending the plant at the electric station in Cotton-street, and considered by the committee. The offerers were English firms, and the prices quoted ranged from £3,300 to £3,860. It was decided to remit the tenders to Prof. Kennedy, London, who will report to a future meeting as to what offer should be accepted. The lowest tender is that of Messrs. Holmes and Co., Newcastle-on-Tyne.

Hanley.—A correspondence has taken place between the Town Council and the Brush Electrical Engineering Company as to the character of the plant and apparatus supplied by them at the Hanley electricity works. The company stated that it was their desire that the equipment of the works should give entire satisfaction, and they agreed to a proposal to send one of their engineers to supervise and be responsible for the running of the plant for a month in order to demonstrate what they believed to be the fact—that the plant was in good working order.

Removal.—The Nalder and Harrison Construction Syndicate, Limited, writing from Trafalgar House, Great Newport-street, Charing Cross-road, inform us that owing to the increase of business they have found it necessary to transfer their offices to 47, Victoria-street, S.W., to which address all communications should in future be sent. The works will continue to be at Trafalgar House, the space hitherto used for offices being converted into additional workshops. The syndicate have also opened a branch office at 33, Old Broad-street, E.C.

Dundee.—The question of the extension of the mains in order to supply the technical institute in Small's Wynd with the electric light has been under the consideration of the Gas Committee of Dundee Town Council. It appeared that a capital expenditure of about £500 would be required for the purpose, and that the Institute Committee hesitated to pay that amount. The Gas Committee, after considerable discussion, decided that they could not incur so large an outlay outside the district prescribed by statute, and the town clerk was instructed to communicate that resolution to the Institute Committee.

Appointment Vacant.—An assistant electrician is wanted by the Manchester Corporation. He will have to take charge of an eight-hour shift, must have had technical education, and passed through the usual routine of pupilage. It is essential that he shall have had central-station experience of boilers, engines, dynamos, secondary batteries, and switching gear. The salary is £2. 10s. per week. Applications to be made in writing, with copies of testimonials, and forwarded to the Gas Department, Town Hall, Manchester, not later than the 15th inst., addressed to the chairman of the Gas Committee, and endorsed "Application for Assistant Electrician."

Pretoria Lighting Company.—A communication from Johannesburg dated November 5 says: "At the meeting of the Pretoria Lighting Company on Tuesday, the new contract with the Government cancelling the electric and gas concessions and extending the contract for the lighting of the town for 15 years was adopted, and also a reconstruction scheme and an offer of Messrs. Lewis and Marks, Eckstein and Co., and Julius Jeppe, guaranteeing to advance up to £40,000 on debentures of the company, shareholders having the right to participate in the application for debentures *pro rata* to their holdings. The report and accounts were also adopted. The new scheme will take effect from December 1."

Belfast.—The Town Council have approved of a formal report presented by the Electric Light Committee. Councillor Harrison said that Alderman Pirrie six months ago had announced to the Corporation that about November they would have the electric light. He wished to know when they were likely to have it. Councillor Reid asked how many of the citizens had applied for the electric light. Alderman Pirrie, in reply, pointed out that it was little more than six months ago since the committee was appointed. It would probably be January before the light was ready to be given to the people who applied for it. In answer to Councillor Reid's question, he said that about one-fourth of the installation had been already applied for by various people.

Lancaster.—On Saturday the Morecambe Electric Light Company were summoned by the Morecambe Local Board for causing an effluvia which was a nuisance and injurious to the health of the inhabitants. The works of the company are in the centre of Morecambe, and in the generation of electricity they use as motive power engines driven by water-gas, in the manufacture of which the smells complained of were caused. Mr. Callis, of Blackburn, urged on behalf of the company that the gas manufactured was passed through tanks of water, and the tainted water turned into the main sewer, and that the sewer traps of the houses being defective allowed the smell to come from the sewer. The magistrates fined defendants £1 and costs, and the company undertook to abate the nuisance.

Fleetwood.—Mr. R. Walton has held an enquiry at Fleetwood with regard to the Improvement Commissioners' application for borrowing powers for the proposed electric lighting scheme. Mr. J. Tildeley, town clerk, stated that the Board wished to borrow £11,816. Mr. Geipel (of the Brush Electrical Company) explained that the scheme proposed to be adopted was the alternating system, 100-volt, fed by high-tension feeders. Mr. S. Fletcher, secretary of the Fleetwood Tradesmen's Association, and Mr. R. F. Addie (Fleetwood Estates Company) supported the application. Mr. Sutton (barrister) made a few observations on behalf of the railway company, who opposed the scheme. There were other schemes which were much more pressing—viz., sewerage. The electric light was only premature yet.

Glasgow.—The work of placing the fittings for the electric light in the new cars is going on apace, and within the next few weeks the people of Glasgow will have an opportunity of judging of the merits of the new illuminant. So anxious is the London company who has the work in hand to make a speedy success of it that during the last week not only has the inventor (who is the managing director of the concern) been at Coplawhill and Kinning Park superintending the work, but other directors from London have also been on the scene. That the work is of some magnitude may be shown by stating that for the 350 cars a stock of 2,800 accumulators will be necessary. These, with half that number of lamps, globes, and fittings, had all to be made specially for the contract, which was only signed some two months ago.

Western and Brazilian Telegraph Company, Limited.—The representative of the companies in Rio de Janeiro advises the London office that an amendment to the Budget was presented on Saturday by the commission, and officially published on Sunday, to the effect that the Brazilian Government is authorised to purchase the undertaking on the conditions of the contract, and also to make the necessary credit operations for the purpose. The Bill is now before the Chamber. For the past week the receipts of the Company were £3,353. The following telegram has been received from the Western and Brazilian Telegraph Company's representative in Rio de Janeiro: "Urgent—4th, 5 p.m.—Amendment to Budget presented by Commission of Public Works passed to-day in third discussion. It now forms part of Budget, which goes to Senate to-morrow."

Aberdeen.—The town clerk, at a meeting of the Town Council, read a letter from Messrs. New and Mayne, electrical engineers, stating that, as the Chamber of Commerce had expressed dissatis-

Digitized by Google

faction with the telephonic service, it was now a favourable opportunity for the Council to consider whether they should have a system of their own, managed by themselves. The firm expressed their readiness to give the Council the necessary information. Treasurer Bisset suggested that the letter should be sent to the Finance Committee, to whom a remit was made some time ago in regard to this matter. The committee had been waiting until the agreement between the National Telephone Company and the Postmaster-General should be made known. After that they intended to recommend the Council to make application for a license. The treasurer's suggestion was agreed to.

Edinburgh.—On the motion of Messrs. Mackenzie and Cranston, it was remitted to the Lord Provost's Committee of the Town Council to consider and report as to whether it is desirable at this stage to arrange for laying down electric light high-tension cables from the station to Nicolson-street for the purposes of supplying domestic lighting through transformers. Some discussion took place on this motion, the contention of some members being that it was not desirable to proceed further with the electric light until the installation as at present adopted had been tried. Mr. Mackenzie explained that under their Act if six or more of the citizens made a requisition for light, the Council was bound under certain conditions to give them the light, and this motion was for the purpose of showing how best that could be carried out economically, as such a requisition had been received. On the Lord Provost explaining that this was a motion merely to obtain information, it was adopted.

Birkenhead.—An enquiry has been held by Mr. R. Dalton, M.I.C.E., an inspector under the Local Government Board, into an application by the Birkenhead Town Council for sanction to borrow £20,000 for purposes of electric lighting £10 000 for works of street improvement and sewerage, and £5,000 for the erection of a fire station. The town clerk (Mr. Alfred Gill) represented the Corporation, and there was no opposition to any of the proposed schemes. Mr. Shoolbred, the engineer, explained the intentions of the Corporation with regard to electric lighting, and said it was proposed to supply with this means of illumination a district embracing a mile radius from the generating station, which would be situated in a position to take in all the principal thoroughfares of the borough. Low pressure would be used, so that accidents such as those which had occurred in London and elsewhere, where high pressure was in use, would be almost impossible. It was proposed to fill the street boxes with oil, as was done in Brighton, where there had never been an accident of any sort, or even extinction.

Guildford.—A meeting of the founders of the Guildford Electricity Supply Company, Limited, has been held at the County and Borough Halls. Mr. A. F. Asher was voted to the chair. Mr. Sidney Sharp, the engineer, proceeded to give at some length the history of the negotiations which took place between the company and the Guildford Corporation, and explained the difficulties in the obtaining of the order consequent on the opposition of the Corporation. Eventually, however, they were successful in obtaining an exceedingly good order, which had received the Royal assent, and which gave them a practical monopoly of the electric lighting of the borough for 35 years. There were very few, if any, other companies which had obtained such good terms. Almost immediately after the order was obtained, the holidays intervened, and it was only recently that they had again been making progress with the matter. The meeting then proceeded to the consideration of formal business, and steps were taken for the issue of the prospectus and the appointment of directors. The share capital is £20,000.

Peterborough.—The Lighting Committee of the Town Council have reported as follows: "At a special meeting for the purpose of considering what action should be taken with respect to the powers obtained by the Corporation in the matter of electric lighting, and in pursuance of a resolution passed that the Corporation take steps to establish an electric lighting installation in accordance with the powers vested in them, the engineer read a further report, in which he gave his opinion and information upon the subjects of (1) the site of the proposed central station, (2) the system of supply, and (3) the preparation of the scheme. A discussion of considerable length ensued, and it was resolved "that the engineer draft a form of circular to be sent to the inhabitants within the compulsory area, with a view of putting before them as nearly as possible the terms of the proposed supply, and ascertaining the extent of the demand; that he have his report printed and supplied to the members of the committee; and that he also prepare a further report, with estimates, etc., showing what consumption would be required to produce an income sufficient to pay the capital and working expenses of such an installation as he proposes."

Tramways Company of France Limited.—An extraordinary general meeting of this Company was held on Monday at the Cannon-street Hotel for the purpose of considering resolutions for the increase of the capital of the Company by the creation of 15,000 new shares of £10 each, to be preference shares, and entitled to a cumulative dividend at the rate of 6 per cent. per annum, and authorising the directors, if they think fit, to sell the 7,094 shares of 500f. each in the Rouen Tramways Company belonging to this Company "for such sum as, after satisfying or providing for the liabilities of this Company, shall be equal to 30s. per share on the 14,248 issued shares of this Company." Lord R. H. Browne occupied the chair. The Chairman proposed the resolutions and explained the reason of the course proposed—viz., the substitution of electric traction for horse power. He said for some months past tramways had been very successfully worked at Havre by means of electricity, and there was a strong feeling in favour of that system at Rouen, where, if they did not adopt it, they were threatened with opposition. It was expected that permission would be given by the authorities to use overhead wires, and an application had been made for an extension of the term of the concession for 26 years, making 50 years to run from the present time. That application was likely to be granted if electric traction were adopted. After a short discussion, the motion was carried by four votes to two.

New Electric Launch.—A new electric launch has been built to the order of Messrs. Mavor and Coulson, of 57, West Nile-street, Glasgow, by Messrs. Denny and Bros., Dumbarton, to the design of Mr. T. L. Watson. This launch, according to the *Steamship*, is suitable for use in harbours and on lochs. It is intended for hanging at the davits, and is constructed so as to give the maximum of strength with the minimum of weight. The hull is made of a double skin of cedar wood, laid on diagonally, the two layers crossing each other. The motor is placed towards the stern and low down, a wooden cover protecting it from injury. The power is derived from a set of accumulators placed under the seats, which extend round the sides of the boat. The supply of current to the motor is regulated by a switch under the control of the steersman. The batteries hold a charge sufficient to propel the boat at a speed of 6·38 miles per hour for 5·7 hours, or a total distance of 36·36 miles, or at a speed of 4·5 miles per hour for 9·75 hours a distance of 43·2 miles. The recharging of the cells is done alongside the vessel or on the davits. The launch has round her a cork fender about 8in. square. This is said to be sufficient to support the launch when filled with water and with four passengers. The motor is of the Sayers type. The dimensions of the launch are: length, 27ft. 6in. by 4ft. 9in. The weight of the boat and fittings is 14cwt.; machinery, including cells, switches, etc., 1 ton 2cwt.; awning, fenders, etc., 2cwt. 3lb., being a total of 1 ton 18cwt. 3lb. The "Velvo," to whose trial on the Thames we recently referred, is also equipped with a Sayers motor, which was made by Messrs. Mavor and Coulson.

Cardiff.—A special meeting of the Electric Lighting Committee of the Cardiff Corporation was held on Thursday last week, under the presidency of the Mayor (Alderman Carey). Out of the three candidates chosen at a previous meeting for the position of foreman of the works, Mr. Charles H. Yeaman, of Victoria-street, London, was accepted. Some discussion took place in reference to the disappointing results of the installation. Mr. Massey explained that everything which had been done so far was in the way of an experiment by the contractors. Those experiments had not been quite satisfactory. He would suggest that the lighting of the public lamps should be postponed until there was a sufficient "load" on the engines. Alderman Jacobs thought this was not a very fair statement of the matter. In the first place, the rectifiers and other portions of the machinery had gone wrong, then when the machinery was put right there was not sufficient "load" to run the current steadily enough. The Mayor explained that the machinery had not yet been taken over by the Corporation. The lighting of the town or such portions of the town in which electric lamps had been erected was entirely experimental on the part of the contractors. Two or three members of the committee stated that in view of the supply of electrical energy tradesmen had given notice to discontinue the supply of gas, and it was explained that there would be no difficulty in supplying the private incandescent lights. A long discussion followed on several points connected with the electric lighting, and eventually a resolution was carried by which the contractors were asked not to attempt any more experiments until they had received a further intimation from the Corporation.

Dover.—A discussion has taken place in the Town Council on the subject of the renewal of the contract with the gas company for street-lighting. Alderman Peake (who is a director of the gas company) explained the details of the letter and pointed out that the lighting of the streets from the Market-square to Buckland Bridge by the incandescent light under terms offered by the gas company would be a saving of £38. 5s. a year on what is paid for the ordinary lamps, and if this experiment were tried and justified the directors in so doing, they would be pleased to consider an extension of this form of light. The Mayor (who is chairman of the Dover Electricity Supply Company) said they would bear in mind that for the last eight or nine years the ratepayers had really been at the mercy of the gas company, which had practically made its own terms as to the price per lamp they should charge. They must not forget that it was the electric light company, and that company only, which had brought the gas company to their bearings. Having done that, were the Council going to desert the electric light company at the very time they most required assistance? The electric company had been the actual lever by which the gas company had been brought to their bearings. The question would have to be proved which was the cheapest and best illuminant, and the advantages and disadvantages of the two lights. The Town Clerk said the gas contract would run out on December 31. After a deal of warm discussion, during which Alderman Pepper pointed out that it had been ruled over and over again that any member of such a body as the Council holding shares or being the director of any company should not endeavour to influence them, a statement which was borne out by the town clerk, it was decided to postpone further consideration of the subject.

Chester.—On Wednesday Mr. Wm. Jno. Bird Clerke, M.I.C.E, an inspector of the Local Government Board, held an enquiry at Chester Town Hall respecting the application of the Chester Town Council for sanction to borrow £25 000 for the purpose of electric lighting, and to appropriate a portion of the Tower Field Gardens as a site for the generating station. The Mayor (Mr. W. H.

Digitized by Google

Churton), the town clerk (Mr. S. Smith), and a large number of members of the Town Council attended. The Town Clerk, in the course of an explanatory statement, said the land in question which was to be appropriated for the installation belonged to the Corporation. The proposal was to provide a generating station in the Tower Field Gardens with a distributing station at the back of Hamilton-place. The area of supply was the whole of the city, but what was usually termed the compulsory area of supply comprised Northgate-street, Bridge-street (not including Lower Bridge-street), Eastgate-street, Watergate-street, Grosvenor-street, to opposite the gate of Chester Castle, John-street, and Pepper-street. Mr. Smith then gave a history of the various stages through which the question passed before the Corporation since 1889, stating that the Council from the outset had been strongly of opinion that it was better, in the interests of the citizens, to retain the electric lighting in their own hands. The estimate furnished by Dr. Hopkinson for the first installation, including contingencies and engineering expenses, was £19,697, and therefore was within the vote of the Council; but if street-lighting were included, and if in the course of the development of the works the demand arose in the first year or two, Dr. Hopkinson thought they might have to spend £25,150. The Council for that reason thought it better to ask the Local Government Board, in the first instance, to assent to the expenditure of £25,000, the whole of which, of course, would not be spent except under the order of the Town Council.

New Swindon.—A special meeting of the Local Board has been held to consider and, if so determined, to pass a resolution to the effect that application be made in the ensuing session to the Board of Trade for a provisional order under the Electric Lighting Acts, 1882 and 1888, to authorise the Local Board to supply electricity for public and private purposes within their district. Mr. Adams asked the length of time over which the provisional order would hold good, and also the probable cost. The Clerk said he did not think there was any limit to time, but it was usual to carry out the order within two years or the order might be cancelled. The area proposed to be included was the whole district, as it was impossible to say now what portion of the district should be dealt with first. They might get the order restricted to some particular area. Mr. Adams said he thought they should not proceed with this matter now if it was going to cost £300 or £400. The Deputy-Clerk: You have to deposit £50 with the Board of Trade, and it may not cost you much more than another £50. The Chairman: There is a strong probability that it will not cost more than £200. Mr. Fox was not in favour of spending any money until the new council was in power. Mr. Longland proposed that the necessary steps be taken to obtain the provisional order. If a certain portion of lamps were taken by private consumers, it would result in a saving of money to the Board and the whole community. The members of the Board would all agree that they would like a better light than they had in New Swindon at the present time from the gas. By adopting this course now they would be securing for the new body who would succeed them a position which they could not otherwise obtain for another year if this step was not taken. Mr. Protheroe seconded the proposition, believing it would be beneficial to the town in the end. The proposition was carried, Mr. Jones dissenting. On the proposition of Mr. Batt, seconded by Mr. Mills, the Board decided to make a formal memorial to the Board of Trade in the matter.

Brighton.—At yesterday's meeting of the Town Council the Lighting Committee submitted a report they have received from their electrical engineer with reference to the extensions which he considers it will be necessary to make during the ensuing year to the electricity generating station and plant therein, in order to cope with the increasing demand for the supply of electricity throughout the borough. In this report it is stated that whereas in 1891 the number of lamps connected was 5,706, in 1892 the total was 11,229, an increase of 5,523; in 1893, 17,760, an increase of 6,531; and in 1894, 28,000, an increase of 10,240; this last total being exclusive of the 10,000 lamps taken over from the Brighton and Hove Company. Assuming, in order to be on the safe side, the rate of increase during the past year will continue, it is estimated there will be connected to the system in the winter of 1895 something like 48,000 lamps, and that in that year the sale of electricity will be about 1,000,000 units, representing at present prices a revenue of about £25,000. As the present works are just sufficient to supply this winter's demand, the necessity of extensions being made during the next year will. it is remarked, be obvious. It is proposed that these extensions should be regarded as part of the general scheme for ultimately bringing up the generating capacity of the North-road central station to supply about 200,000 lamps, which is about the limit it is considered advisable to supply from that site. The extension now recommended includes the erection of new chimney shaft 200ft. high, a second boiler-house, and an enlargement of the engine-room to double the present size; and the addition of six boilers, two steam dynamos, etc. This additional machinery will provide for an increase in the number of lamps supplied from the generating station from 38,000 8-c.p. lamps (22,800 alight at one time) to 62,000 8-c.p. lamps, of which 37,200 may be alight at the same time, still maintaining one-fifth of the power in reserve. It is recommended that a loan of £42,000 be obtained for a period of 40 years to defray the cost of the proposed works, the estimate including an item of £1,000 for mains for the purposes of street-lighting.

Hampstead.—The Works Committee of the Vestry reported that they had considered the question of lighting the Vestry Hall with the electric light, together with a report from the electrical engineer on the subject, and found that the probable cost of the installation would be £420; that the present cost of lighting by gas was about £80. 12s. 11d. per annum, and that the cost of lighting by electricity was estimated at £88. 4s. per annum; and that, pursuant to the authority delegated in that behalf, the committee had given instructions for certain electrical engineering firms to be invited to submit tenders for carrying out the installation in accordance with the specification of the Vestry's engineer. The Vestry approved of the report. The Electric Lighting Committee recommended that Messrs. Yerbury and Sons be paid the sum of £589. 12s. for the cartage of clay in connection with their contract as and when the architect shall so certify, and that they be also paid the sum of £1,112. 19s. 6d. for extra works in connection with their contract as and when the architect shall so certify; that electric lighting mains be laid in Dalehamgardens at a cost of £308, and from the junction of Gayton-road and High-street to the Vestry Hall at a cost of £1,050; that a transformer and necessary fittings be obtained for the use of the stoneyard installation at a cost of £20. 5s. 6d.; that the engineer be authorised to obtain dies at a cost of £8. 10s. This report was adopted. The same committee reported that they had accepted the tender of Messrs. Yerbury and Sons for erecting the shed at the rear of the station, already sanctioned by the Vestry, for the sum of £56, the work to be carried out to the satisfaction of the surveyor; that they had given instructions for the engineer's cash account for station expenses to be paid monthly; that they found that the cost of the gas supplied to the town clock amounted to £30 annually, and that the cost of installing the electric light therein would be £20, and it was estimated that the annual cost of that light would be £36, and they recommended that the committee be empowered to take the necessary steps to cause the town clock to be lighted by electricity. On the suggestion of the chairman, this recommendation was withdrawn pending the election of a new Vestry.

South Staffordshire Tramways Company. — The case of Marshall *v.* the South Staffordshire Tramways Company has been before the Chancery Court again on the question the form of order was to take. This was a debenture-holder's action, and the difficulty was in respect of the person acting as manager since the date of the order. At present there was no money to pay the wages of the servants and to keep the concern going. Mr. Bramwell Davis, who moved in the matter, said he was prepared to offer on behalf of a responsible man that only the net earnings should be handed over to the receiver. After some discussion, Mr. Justice Kekewich intimated that he should discharge the manager and order him to give up the direction of affairs. Mr. Davies said Mr. Dickinson, who was acting under Mr. Gully, declined to do anything or to pay over the wage money. After some argument, Mr. Davies said he presumed Mr. Dickinson would hand over the money. Mr. Warmington, Q.C., replied that Mr. Dickinson was Mr. Davies's servant. The matter then dropped. Mr. Buckley, Q.C., has appeared in support of the petition of Messrs. W. Smallman and others, trade creditors, for a compulsory order to wind up this Company, which had a capital of £86,580 in preference shares and £129 650 in ordinary stock. The stock had all been issued. In May, 1893, Mr. Justice Kekewich heard a debenture-holders' action, and appointed receivers and managers. On November 21 last he discharged the order as to managers, and appointed Mr. Sully sole receiver. This put the receipt of the takings in the hands of the directors, and they now had filed an affidavit which practically confessed insolvency. Mr. Theobald, for the Electric Construction Company, who had supplied the electric motive force, etc., said his Company had only received 6d. out of 9d. per mile agreed, and there was still a large sum due. He supported the petition. Mr. Swinfen Eady, Q.C., opposed the petition on behalf of the Company. Mr. Justice Williams said the debts of the petitioners were small trade debts, and he did not see why the directors should not pay them now they had the management of the Company in their own hands. The tramway was going on and money coming in daily. He should, however, require to hear more about the petition, because he was not satisfied it was a *bonâ fide* trade creditors' petition. Petition adjourned for a week.

Westminster Electric Supply Corporation, Limited.—An extraordinary meeting of holders of founders' shares in the above Corporation will be held at the registered office, Eccleston-place, Belgravia, S.W., on Thursday, 13th inst., at 10.45 o'clock in the forenoon, when the following resolution which was passed at an extraordinary meeting of the holders of founder's shares held on the 28th ult., will be submitted for confirmation as a special resolution: "That the assent of the holders of the founders' shares be given to the proposals for issue of new share capital to be presented to the shareholders at a meeting to be held this day—viz., that out of the newly-created share capital of £100,000, £40,000 in 8,000 shares of £5 each be forthwith issued at a premium of £1 per share, and in the first instance allotted to shareholders on the register on November 14, 1894, in the approximate ratio of one to every complete eight shares then held, and that the Board be empowered to allot any balance of the 8,000 shares not allotted to the shareholders to members of the staff of the Corporation, or to such other persons as they may think fit on the same terms. That the amount due on the shares be payable as follows: £1 (premium) on January 3, 1895; £2 on January 15, 1895; and £3 on July 1, 1895, and that the new shares rank for dividend (on amount of capital paid) from January 1, 1895. That the balance of 12,000 shares be retained, and that the Board be authorised to issue them as required, they being first offered to the shareholders on the register at the time of such issue, and on such terms as the Board may consider desirable." An extraordinary general meeting of the shareholders of the

Digitized by Google

Corporation will then be held, at 11 o'clock, when the following resolutions which were passed at an extraordinary general meeting held on November 28, 1894, will be submitted for confirmation as special resolutions: "That out of the newly-created share capital of £100,000, £40,000 in 8,000 shares of £5 each be forthwith issued at a premium of £1 per share, and in the first instance allotted to shareholders on the register on November 14, 1894, in the approximate ratio of one to every complete eight shares then held, and that the Board be empowered to allot any balance of the 8,000 shares not allotted to the shareholders, to members of the staff of the Corporation, or to such other persons as they may think fit on the same terms.—That the amount due on the shares be payable as follows: £1 (premium) on January 3, 1895; £2 on January 15, 1895; and £3 on July 1, 1895, and that the new shares rank for dividend (on amount of capital paid) from January 1, 1895.—That the balance of 12,000 shares be retained, and that the Board be authorised to issue them as required, they being first offered to the shareholders on the register at the time of such issue, and on such terms as the Board may consider desirable."

PROVISIONAL PATENTS, 1894.

NOVEMBER 26.

22856. **Instruments for measuring the frequency of alternating or periodically varying electrical currents.** Hermann Clark Haycraft, 48, Breakspears-road, Brockley, London.

22866. **A regulating lever-action (dummy) "sounder" practice telegraph instrument.** Frank Edward Morriss, Postal Telegraph Office, King's Lynn, Norfolk.

22880. **Electric arc lamp.** Radley Mott Trille, Egyptian Lodge, Val Plaisant, Jersey.

22883. **Improvements in electrical measuring instruments.** Gustav Binswanger and Edward Stanley, 73, St. Stephen's-road, Upton-park, London.

22890. **Improvements in apparatus for the manipulation of electric or limelight boxes, scenes, curtains, and wings operated by electric current.** Arthur Taylor, 106, Priory-park-road, Kilburn, London.

22919. **An electrically-driven hydro-extractor.** Thomas Barnet Grant, 15, George-street, Mansion House, London.

NOVEMBER 27.

22965. **Improvements in or relating to electrically heating metal or other conducting bodies or welding metals electrically.** William Phillips Thompson, 6, Lord-street, Liverpool. (Charles Lewis Coffin, United States.) (Complete specification.)

22966. **Improvements in or relating to the production of compounds applicable for such uses as for paints for electric insulating and waterproofing, as substitutes for vulcanisable rubber and gum compounds, and for other purposes.** William Phillips Thompson, 6, Lord-street, Liverpool. (William Griscom, jun., United States.) (Complete specification.)

22973. **Improvements in and relating to storage batteries.** Charles Stephen Wheatley Brown, 3, Ellacomb-villas, Hertford-road, Edmonton, London.

22985. **Improvement in the means of fastening to incandescent electric or other lamps and globes any shade or ray diffuser.** Ernest Oldenbourg, 11, Warwick-street, Regent-street, London.

22986. **Improvements in and relating to primary batteries for producing portable electricity for light and power and other purposes.** Charles Jones Hubbell, 46, Lincoln's-inn-fields, London. (Complete specification.)

23012. **Electric signalling systems.** Horace Everett Walter, 40, Chancery-lane, London. (Complete specification.)

NOVEMBER 28.

23083. **Electrical and mechanical appliances for extracting shives, etc., from casks and other vessels and examining them inside.** Joseph Thomas Thompson and Alfred Slatter, De Frene-road, Sydenham, London.

23098. **Improvements in the feed-regulating mechanism of electric arc lamps.** William Kirkham Partington, 11, Furnival-street, Holborn, London.

23117. **An improved electrolytic process and apparatus for obtaining rich alloys of the metals of the alkalies or alkali earths and the production of halogen elements.** Léon Paul Hulin, 53, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, May 5, 1894, being date of application in France.)

NOVEMBER 29.

23159. **Improvements in and relating to electric brushes and such like.** Edward Lewis Levetus, 47, Vittoria-street, Birmingham.

23160. **Improvements in and relating to primary batteries and such like.** Edward Lewis Levetus, 47, Vittoria-street, Birmingham.

23177. **Improvements in dynamos.** Anthony George New and Arthur James Mayne, 55, Chancery-lane, London.

23203. **Improvements in the application of springs for electrical switches and other purposes.** William Thomas Burbey, 570, Hatton-garden, London.

NOVEMBER 30.

23219. **Improvements in the method of fixing electric arc lamps, with special reference to ease and safety for adjustment, trimming, etc.** George Marshall Harris, Bray Electric Light and Power Station, Bray, Ireland.

23250. **Improvements in gauges of electric exhaustion, positive and negative, caused by surroundings, buildings, or atmosphere.** Edmond Savary d'Odiardi and Eva Savary d'Odiardi, 218, Gloucester-terrace, Hyde Park, London.

23279. **Improvements in electrically-propelled carriages for common roads.** Frank King, 47, Lincoln's-inn-fields, London.

DECEMBER 1.

23294. **An improved electrical lamp.** Edwyn Grahame, 56, Sanscroft-street, Kennington, London.

23297. **Improvements in and relating to an apparatus and a method for causing chemical changes of gases and mixtures of gases by dark electric discharges.** Nicolas van der Sleen and August Schnellen, 37, Chancery-lane, London.

23354. **Improvements in and connected with the electric lighting and heating and also the ventilation of railway carriages and other vehicles.** Edwin James Preston, of the firm of J. Stone and Co., and Arthur Bernard Gill, 77, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1893.

21434. **Electrically-heated ovens.** Schindler.

1894.

249. **Electric switching apparatus for electrically-propelled vehicles.** King.

444. **Electric light fittings.** Northcote and Verity.

1657. **Communicating electricity to vehicles.** Holt.

17281. **Converting alternating into direct currents.** Still.

17365. **Raising and lowering electric or oil floor standards, etc.** Braham.

18910. **Electrolytical vessels.** Jensen. (Cappelen and another.)

19185. **Electric switches.** Stevens and Kesteven.

19186. **Electric thermostatic fire-alarms.** Rowand.

NOTES.

Electric Lighting in Italy.—The communes of Desenzano and of Montechiari are to be provided with a central electric station.

Train-Lighting.—The railway postal vans running between Frankfort-on-the-Maine and Basle are now lighted electrically from accumulators.

Technical Institutes.—A meeting has been held at Wandsworth Town Hall in furtherance of the project to establish a technical institute in the locality.

London Chamber of Commerce.—Lord Brassey will on Tuesday afternoon next deliver an address in the council-room, Botolph House, on "The Indian Currency Question."

Bedford Central Station.—As notified in another column, this station was started last week, since which time a supply of the electric light has been available both day and night.

Lecture.—The members of the Newport Literary Society were on Friday evening entertained to a lecture by Mr. R. Hammond, the consulting engineer to the Corporation, on "The Electric Light."

Gas Does Not Pay.—It appears that the Rotherham Town Council have during the past half-year made an approximate net loss of £1,993 on the working of the gas-works. They had better now give electric light a trial.

Gustavus Adolphus.—In connection with the celebration of the three hundredth anniversary of the birth of Gustavus Adolphus in Stockholm, the Gustavus Adolphus monument was illuminated at night by thousands of electric lights.

Telephony in Austria.—Telephonic communication has been established between Vienna and Linz, thus connecting Lower and Upper Austria. The subscribers can also be switched on to St. Pölten, Wilhelmsburg, Lilienfeld, and Hainburg.

Electric Construction Company.—We are informed by the Electric Construction Company, Limited, that Mr. Garcke will retire from the position of managing director of the company upon the expiration of his agreement at the end of the year.

Society of Arts.—On Monday, at 8 p.m., the fourth Cantor lecture on "Modern Developments in Explosives," by Prof. Vivian B. Lewes, will be delivered. On Wednesday, at 8 p.m., a paper on "Forestry," by General J. Michael, C.S.I., will be read.

Empire of India Exhibition.—The corner-stones of the Imperial Palace and Empress Theatre, which are to form part of the forthcoming Empire of India Exhibition at Earl's Court, were laid on Wednesday. The exhibits will include electrical appliances.

Long-Distance Telephony.—The works of Messrs. George Angus and Co., of Cardiff, have just been put in communication with their establishment at Newcastle-on-Tyne by the G.P.O. trunk line. The distance between the two towns is upwards of 300 miles.

Institution of Engineers and Shipbuilders.—The third general meeting of the North-East Coast Institution of Engineers and Shipbuilders will be held on Wednesday next, in the lecture hall of the Subscription Literary Society, Fawcett-street, Sunderland.

Companies Acts. — The council of the London Chamber of Commerce have decided to form a special committee for the purpose of preparing suggested amendments in the Companies Acts, and to supply information to the Board of Trade Committee, which has just been appointed.

Liverpool Engineering Society.—The fifth ordinary meeting of the session will be held at the Royal Institution, Colquitt-street, on Wednesday next, the 19th inst., at eight o'clock, when a paper, entitled "The Second Law of Thermo-Dynamics," will be read by Prof. Oliver J. Lodge, D.Sc., LL.D., F.R.S.

Personal.—Sir David Salomons has decided to signalise his mayoralty of Tunbridge Wells by a New Year's dinner, to which 300 guests will be invited.—Mr. Mavor, of Glasgow, has been retained by the Wishaw Town Commissioners as electrical engineer in connection with the proposed electric lighting of the town.

Naval Electricity.—Plans have been forwarded to the Admiralty of the new electric shop in Portsmouth Dockyard, and it is hoped it will be shortly proceeded with. One part of the convict prison will be utilised for the dynamos, but the remainder of the shop will be an entirely new building inside the prison walls.

"Yule-Tide."—Messrs. Cassell and Co. send us a copy of this Christmas annual, which comprises "The Avenger of Blood," a novel by Mr. J. McLaren Cobban; a large coloured plate, by Mr. W. E. Britten, of two children and a dog playing hide-and-seek; two smaller coloured plates of ducklings, toads, and chickens, and four plates in tints.

Electro-Medical Exhibition.—Under the auspices of the Société Française d'Electrothérapie, of Paris, there will be held in April next an exhibition of electric apparatus, instruments and generators for physiological, medical, and surgical purposes. The address of the secretary is Dr. D. Labbé, 46, Rue Pierre Charron, Paris.

Telephony in Switzerland.—The Budget of the Swiss Federal Council for 1895 provides for a sum of 133,000f. (£5,320) for telephonic communication between Geneva and Zurich; and for 53,000f. (£2,120) for a telephone line between Lucerne and Basle. Provision will be made in the following Budget for a telephone line between Geneva and Basle.

Electric Lighting in France.—Mr. J. Leroy, the representative in the eastern district for Messrs. Sautter, Harlé, and Co., has undertaken the work of fitting up an electric light installation for the work of constructing the batteries at the Frouard fort, near Nancy. There are six arc lamps and a number of incandescent lamps. The same firm has electrically lighted the Saint-Michel fort at Toul.

The Lighting of the Reichstag Building.—There are employed in the new Reichstag Building, Berlin, which has just been completed, 5,500 incandescent lamps of various candle-power, and 67 arc lamps of from 1,000 c.p. to 4,200 c.p., the total amounting to 180,000 c.p. The work has been carried out by the Berliner Elektricitätswerke, and the arrangements of the lamps as carried out have proved very satisfactory.

Dundee Institute.—The first ordinary meeting of the Dundee Institute of Architecture, Science, and Art for the session was held in the hall of the Young Men's Christian Association yesterday (Thursday) evening, when a lecture was delivered on "Some Principles of Decoration, in Marble, Mosaic, Sculpture, Painting, etc.," by Mr. Alexander N. Paterson, M.A., A.R.I.B.A., architect, Glasgow, president of Glasgow Architectural Association.

New Mode of Mill-Lighting.—A new system of lighting has been introduced by Mr. Lester Betts, the manager of the Calcutta branch of the Oriental Telephone and Electrical Company, Limited, in the case of the Empress of India Cotton Mills, at Budge-Budge, which are entirely lighted from the outside, special zinc fittings with 50-c.p.

Digitized by Google

lamps being fitted to each window. This system, which has proved a complete success, saves the extra premium for fire insurance.

Electric Traction in Austria-Hungary.—There is a perfect epidemic of electric traction projects for Vienna. Among the schemes at present before the public are proposals by the Allgemeine Elektricitäts-Gesellschaft, of Berlin, by the Anglo Bank, by the Austrian Länderbank (in conjunction with the Vienna Tramway Company), by Messrs. Ritschl and Co., by the Kahlenberg Railway Company, by the New Vienna Tramway Company, and by Mr. Hermann Frühe.

Institute of Mining Engineers.—A general meeting of the members of the South Staffordshire and East Worcestershire Institute of Mining Engineers has been held at the Mason College, Birmingham, under the presidency of Mr. Sopwith, when Mr. E. J. Bailey read a paper on the main and tail rope system of electric haulage in operation at Abercanaid Colliery, Merthyr Tydfil. He explained the system in detail, and said that, taking into consideration the character of the work, the results obtained had been satisfactory.

Royal Meteorological Society.—An ordinary meeting of this society will be held at 25, Great George-street, Westminster, on Wednesday next, the 19th inst., at 7.30 p.m. Papers on the following subjects will be read: "Report of the International Committee on the Cloud Atlas," by Mr. Robert H. Scott, M.A., F.R.S.; "Rainfall and Floods in the Catchment Basins of the Severn, Wye, and Usk, November, 1894," by Mr. Henry Southall, F.R.Met.Soc.; and on "Meteorological Observations at Mojanga, Madagascar, 1892-1894," by Mr. S. C. Knott.

Quinquennial Rating Rovision, 1895.—The council of the London Chamber of Commerce draw the attention of members interested in manufacturing and industrial premises to the fact that in April next the assessment committees will make their quinquennial revision. From information already placed before the council, it would appear probable that these committees will suggest considerable increases. In order that the way may be prepared for such united action as may be found desirable at the proper time, the council have issued a form putting questions on the subject.

The Electrophone.—Last week a party of visitors was invited to hear the new instruments provided by the Electrophone Company, which is organising arrangements by which the music and performances at the theatres, sensational cases at the Law Courts, and other interesting electrophonic transmissions of sounds can be heard at various stations in the Metropolis and its suburbs. Selections from the entertainments going on at the Empire, Gaiety, Lyric, Prince of Wales's, and Daly's were given. The entertainment was given in one of the apartments of Pelican House, Gerrard-street, Shaftesbury-avenue.

Northern Society of Electrical Engineers.—The following is the list of officers and council for 1895, as elected at the annual general meeting held on Monday last: president, Mr. Henry Edmunds; past-president, Dr. John Hopkinson, F.R.S.; vice-presidents, Mr. G. E. Preece and Mr. W. P. James Fawcus; hon. solicitor, Mr. John B. Parkinson; hon. treasurer, Mr. George J. Somerville; hon. secretary, Mr. John Darney; and members of council, Messrs. A. B. Blackburn, Thomas Browett, E. A. Claremont, S. V. Clirehugh, G. S. Corlett, E. W. Cowan, C. M. Dorman, G. W. Lowcock, E. Manville, J. H. Rider, James Taylor, and C. H. Wordingham.

Gulcher Thermopiles.—To those interested in the subject of thermopiles we commend for consideration an article by Mr. C. Brüggemann published in the *Elektrotechnische Zeitschrift* of November 29. The author, who is one of the assistants at the technical high school, Aix-la-Chapelle, deals with measurements undertaken by him at that school with the Gülcher thermopile, in which slight improvements have been made. The thermopiles tested were four, each comprising 66 cells. Two of these (Nos. 263 and 228) were in operation about 200 hours; No. 333 was longer in use, but not over 500 hours; whilst the fourth (No. 306) has for almost two years served for the charging of accumulators.

Railway Rates.—The London Chamber of Commerce remind members that, as a measure of precaution, complaints to the Board of Trade in respect of increased railway rates under the Act of 1894 should be formulated and deposited not later than the 25th of February next, as there appears to be some doubt as to the precise construction of the section relating to the recovery of over-charges. The test cases referred to in a previous issue are proceeding, and it is understood that the Board of Trade have now received communications from the railway companies on the subject. It has not yet been possible to form an opinion as to when decisions can be given, but it is hoped, the council of the Chamber state, that they may be pronounced early in the New Year by the Railway Commission.

Extinction of the Musical Bore (!).—The *Pall Mall Gazette* young man who hunts about electrical and other matters for that paper is progressing. He did pretty well over "electric belts," but left patent agency business alone. Now he desires to get rid of the musical bore. Who does not? Listen to what he says about one instrument at the musical exhibition opened at the Aquarium on Wednesday afternoon: "One singular application of science to pianos is to be found in an electric piano, which passes a gentle, or if needs be, a severe shock through the frame of the performer. There is a future for an instrument of this kind. If all the drawing-room pianos were only fitted with a thousand volts or so it would be easy to extinguish the musical bore." It is not put very neatly, but it will do. Fortunately we do not live in a musical boring district. If we did, we should only take one vault—of the music-hall type.

State Telegraphy.—There is an expressed desire among those associated with the postal-telegraph system, the *City Press* states, that the twenty-fifth anniversary of the absorption of the telegraph by the State should be made the occasion for a festivity or an exhibition of curiosities. In the present building in St. Martin's-le-Grand, there are over 4,000 persons employed in telegraphy. The cheapening of the telegraph and the facilities offered for the exchange of messages in all portions of the kingdom form one of the wonders of the age, and it is only natural that those interested should desire to make the coming anniversary the occasion for a public demonstration of some kind. It seems to be a fitting opportunity, our contemporary concludes, for the exercise of a little public spirit on the part of the Corporation or one or more of the wealthy livery guilds, seeing that the State is not likely to exert itself in the matter.

Electric and Magnetic Experimental Apparatus.—To those engaged in experimental work, and particularly in colleges and scientific institutions, the new price-list of electric and magnetic apparatus just issued by Messrs. King, Mendham, and Co., of Narrow Wine-street and Fairfax-street, Bristol, comes out at an appropriate moment. Practically every kind of apparatus required for experimental work by lecturers, science teachers, and amateurs is fully detailed in the list. Commencing with

Digitized by Google

Wimshurst influence machines, of the types furnished to the South Kensington Science and Art Department and other scientific establishments, the list passes on to static electromotors, inductive electric machines, electroscopes, electrometers, condensers, and the numerous accessories. Then follow Leyden jars, battery parts, voltaic batteries, and dry batteries, together with magnets and magnetic apparatus, electro-depositing apparatus, Ruhmkorff and induction coils, vacuum tubes, thermopiles, galvanometers, portable testing sets, etc. The list concludes with electric motors, telegraphic and telephonic appliances, incandescent lamps, lanterns, arc lamps, etc.

Effect of the Electric Arc on Carbon.—In the course of the series of experiments undertaken with the electric furnace during the past two years, M. Henri Moissan has had occasion to deal with the vaporisation of carbon. After having detailed his investigations before the French Academy of Sciences, he concludes as follows: (1) that in vacuum, as in ordinary pressure, carbon passes from the solid to a gaseous state without assuming a liquid form, and from this point of view it may be compared to arsenic; and (2) when gaseous carbon reassumes a solid form it always furnishes graphite. M. Moissan estimates, however, that carbon can be brought to a liquid state, but this phenomenon would only be produced under the action of more or less strong pressures. In the case of high pressures, as his previous experiments established, the density of the carbon would increase and the diamond would be obtained. In fact, he has been able to prepare small diamonds. Both at the Cape and in Brazil diamonds are found which possess no trace of apparent crystallisation, and which have rounded forms such as can be taken by a fluid maintained in the centre of a "milky" mass. Carbon under pressure could then take up the liquid state and be solidified as water, either by presenting a confused mass of crystals or by taking a rounded and amorphous form.

Chloride Accumulator Litigation.—The *Electrical Engineer* of New York says: "A decision was rendered on November 15 in the United States Court of Appeals for the Second Circuit, in the case of the Accumulator Company *v.* the Edison Electric Illuminating Company and the Electric Storage Battery Company, by Judge Wallace, affirming the decision of Judge Lacombe enjoining the Edison Electric Illuminating Company, of New York, from using the chloride battery, for the reason that it is an infringement of the Swan reissue patent." Before this confirmation was made, the Electric Storage Battery Company, of Philadelphia, wrote to our contemporary as follows: "In reference to the decision of the United States Court of Appeals for Second District, in case of Accumulator Company *v.* Edison Electric Illuminating Company: The day following the opinion of the Court upon the application of the counsel for the Edison Company, the Court gave leave to file an application for rehearing to be submitted in printed form, and accompanied with a printed argument in support thereof, and denied the motion of the counsel for the Accumulator Company for the mandate, holding that in abeyance until the decision was given upon the petition for a rehearing. The decision in no way affects the business of the Electric Storage Battery Company, but applies solely to the New York Edison contract, and even if affirmed will only delay that work until May next, when the Swan patent expires."

Society of Engineers.—The members of this society held their forty-first annual dinner on Wednesday evening at the Holborn Restaurant, the president, Mr. G. A. Goodwin, in the chair. Among those present were Sir R. Rawlinson, Mr. Alexander Siemens, Mr. J. Bernays, Mr. Jabez Church, Mr. C. Gaudon, Prof. H. Robinson, Mr. W. A. McIntosh Valony, Mr. A. T. Walmsley, Mr. J. W. Wilson, Mr. S. H. Cox, Mr. G. M. Lawford, Mr. W. G. Pierce, Mr. W. W. Beaumont, Mr. W. Bradford, Mr. J. C. Fell, Mr. H. O'Connor, Mr. S. Sellon, and Mr. G. A. Pryce Cuxson, secretary. The usual loyal and patriotic toasts having been honoured, the chairman proposed "Success to the Society of Engineers." In doing so he congratulated the members on the satisfactory position the society had maintained for so many years, and on the increasing number of new members. He pointed out the advantages which would be gained by the younger members, who would one day be called on to carry on their work, from attendance at their discussions and at their visits to works of engineering interest. He thought they should not be discouraged by the high point of scientific knowledge already attained, but should remember that although the field of research was becoming apparently restricted by continued improvements, it was also extending its circumference and thereby furnishing outlets for further discoveries. In conclusion, he advised them, while knowing something of everything, to know everything of something, and so become expert in some one subject.

Whirling and Vibration of Shafts.—The fourth ordinary meeting of the Liverpool Engineering Society was held at the Royal Institution, Colquitt-street, on the 5th inst., the president, Prof. H. S. Hele-Shaw, M.I.C.E., in the chair. The West premiums for the past sessions were presented to Messrs. Morgan and Duncanson. The remainder of the evening was devoted to the reading of a paper "On the Whirling and Vibration of Shafts," by Mr. Stanley Dunkerley, M.Sc., in which the author stated that a shaft, however nearly balanced, when driven at a particular speed bends, and unless the amount of deflection be limited might even break, although at higher speeds the shaft again runs true. The particular or "critical" speed depends on the manner in which the shaft is supported, its size and modulus of elasticity, and the sizes, weight, and positions of any pulley it carries. The formulæ giving this speed have been worked out for two simple cases, with unloaded shafts, by Profs. Rankine and Greenhill. A general theory applicable to all cases has been deduced by Prof. Reynolds, and the author has obtained mathematical formulæ giving the critical speed in terms of the diameter and length of the shaft, weights, and positions of the pulleys, etc., in particular cases applicable to the different conditions under which a shaft works. The formulæ so obtained cover all cases which are likely to arise in practice, and the object of the present paper is to give those results in such a form that they can be applied directly to practice by any ordinary engineer.

Electric Lighting at Agra.—Messrs. A. John and Co. are using the electric light, not only for their business premises, but also for the private dwelling-houses connected with the same. The buildings connected with the firm stand in a compound of about half a square mile, and consist of a medical hall, a store and office, a coach-building factory, a soda-water factory, a printing-press house, and four private dwelling-houses. The engine-room and dynamo-house have been built almost in the centre of the compound and contain a Marshall's 18 h.p. vertical engine and boiler. The dynamo is of the new pattern lately introduced into India by the Oriental Telephone and Electric Company. The medical hall, which is specially fitted up to show off the electric light to rajahs and other native nobility, is illuminated by a massive cut-glass hanging vase in the centre, hanging coloured lamps in each window, and a 300-c.p. lamp in the centre dome of the hall. All the showcases have imitation candle-

Digitized by Google

lamps fixed among the cut-glass scent bottles, etc., and can be switched on or off one by one. The hall is also provided with an electric clock and an electric kettle. The grounds are also illuminated by 50-c.p. lamps in watertight fittings fixed to trees, walls, etc., and the coach building department is fitted with a complete set of lights to work at night in case of press of work. The plant was supplied and erected by the Calcutta branch of the Oriental Telephone and Electric Company, Limited, under the personal supervision of their manager, Mr. Lester Betts, M.I.E.E.

Mr. S. Walker on "Electric Traction."—Mr. Sydney F. Walker, of Cardiff, writes to a local paper as follows: "May I point out that when contemplating the purchase of the Cardiff tramways, it would hardly be wise for the Corporation to look forward to driving the t rams by electricity for several years to come, at the very least. The only system of electric railway that has yet paid for ordinary street work is that in which overhead conductors are used, and that, I imagine, would hardly be tolerated in Cardiff. The accumulator system is barred, even on perfectly level roads, by the excessive cost of renewal of the plates, while their weight is such that no car can carry sufficient accumulators to climb a gradient of 1 in 10 with a full load on a wet day. The underground slot system, which is used at Blackpool, is very expensive and very troublesome. The Blackpool line only pays owing to the special conditions of the traffic, and the dividend is very moderate even with that advantage. Further, the alternate-current system adopted in the Cardiff electric lighting station is not adapted for tramway work at all, as far as invention has gone at present. I believe that not only tramways, but 'buses, and even carriages and carts, will eventually be worked by electricity; but there is a good deal of work to be done before that comes to pass, principally in the direction of lightening and improving the accumulator. Possibly by the time the accumulator is so far improved that tramcars can be worked economically by their aid, the present fancy for alternate currents—the third I have witnessed—may have died out."

Electric Traction Catalogue.—Now that the question of light railways and electric tramways is being so prominently discussed in different circles, special interest will be excited in the "Electric Traction" catalogue just issued by the Electric Construction Company, Limited, of Wolverhampton and Queen-street-chambers, Queen-street, E.C. The great necessity for the substitution of electric for other methods of traction from the point of view of the shareholder is pointed out, and the benefits thereby accruing to the public are also emphasised. The catalogue, which is profusely illustrated, deals first with the storage battery systems, and then with the conduit method as being furnished by the company for Madras. A short line constructed on this principle is to be seen in operation at the works in Wolverhampton. Following is the overhead system, with centre suspension of the trolley wires and arc lamps arranged on the top of the standards. Reference is then made to the system carried out by the company on the South Staffordshire Tramways, where the method of side collection of the current devised by Mr. A. Dickenson has been introduced. A noteworthy point in this connection is afforded by a comparison of this system with the American method of transverse span wires with poles on both sides of the streets, the great difference between the two being prominently illustrated. Further emphasis is laid upon the superiority of the South Staffordshire system by comparative plans showing the method of overhead wiring adopted in the two cases. The success of the Liverpool Overhead Electric Railway is demonstrated, and the catalogue, which will be of value to all interested in tramway working, concludes with photographs of the motor trucks at Birmingham, and of the motors employed at Walsall and Liverpool and of generators.

Cost of Electric Transmission of Power.—Before the North of England Institute of Mining and Mechanical Engineers on Saturday, Mr. Alexander Siemens, president of the Institution of Electrical Engineers, read a paper on "The Cost of Electric Transmission of Power." He said that some time had elapsed since Lord Armstrong and Sir William Siemens installed electricity for this purpose, as well as for lighting, at their respective residences at Craigside and Tunbridge Wells. Those applications of electric transmission were perfectly successful, though it was only lately that the transmission of electric power had been taken up in earnest. First of all, electric tramways were developed, and their rapid extension was sufficient proof that reliable electric motors could be erected, and would work reliably and without trouble. There was a belief in the minds of some people that an electric motor cost about as much for repairs as a steam locomotive did for coal. His firm had electric motors on tramways which had run 60,000 miles without any repairs whatever. If they made a motor sufficiently strong so that it could do its work comfortably, it would not use up the brushes. Mr. Siemens then described the system of electric transmission in use in the works of Messrs. Siemens Bros. and Co. at Woolwich, which has been put in to supersede steam power. The works were lighted from the same generators. If engineers introduced electric power for pumping or hauling in mines they could use the same mains for lighting purposes, and they would find it worked perfectly well. Having given the result of careful experiments as between steam and electricity, he said there could be little doubt about it that for new works electric transmission was the cheapest. Whether a change from the old system to electric transmission could be recommended could only be decided by local circumstances. As a rule, electric transmission was most valuable where power was required to be transmitted to various and distant portions of works, and especially in such places as mines, etc. By the conversion the colliery owner would save sufficient to repay the outlay in 10 years. In other words, the cost of erecting the plant for the year would be less than the present cost by an amount equal to 20 per cent. of the outlay.

"Electric Engines."—This was the subject of a lecture delivered by Prof. Silvanus P. Thompson at the London Institute on Monday last. Starting with a little historical retrospect, the professor pointed out how curiously the now so very obvious principle of the electromagnet evaded discovery in the early years of the century. Experimenters got wrong by sending their currents of electricity through the bar of iron instead of round it. This, of course, was very natural. How could one expect that something would happen inside a house from merely walking round it. Prof. Thompson showed his audience two large examples of electromagnets. A thick bar of iron was instantly sucked up into the centre of one of these "solenoids," and remained gracefully suspended in the air in utter defiance of the laws of gravity. This sucking of a piston into a cylinder suggested to the inventive mind at once a means for making a motive electric engine. Why not have solenoid coils for cylinders, and iron pistons sucked in and out like a steam-engine, and connecting rods and cranks and things? Simply because this was precisely the worst way of harnessing electricity to work that could be devised. On the contrary, the rotatory system, which had proved to be the worst for steam, was the best for

Digitized by Google

electricity. The lecturer explained the various stages of development of the electric motor, pointing out that the ring armature of Pacinotti spinning round between the poles of powerful electromagnets was the original model upon which nearly all dynamos and motors had been framed up to the present day. He pointed out how largely our American cousins use small motors for domestic purposes—to drive fans and turn sewing machines. The United States had thousands of miles of electric tramways running, which had effected quite a social revolution in the towns. Working-men, instead of crowding in confined and unhealthy houses in the heart of the cities, now went home to open suburbs on electric trams at a rate which would probably frighten the Board of Trade in this country. Prof. Thompson concluded by showing the famous experiments with polyphase currents that he recently made at the Royal Institution at the Royal Society's soirée. Pieces of copper, rings, coins, and cylinders were made to gyrate rapidly when brought within the magnetic field without any mechanism whatever. The lecturer declared that in this direction lay an entirely new development in the engineering possibilities of electricity.

Electric Lighting in Germany.—The Allgemeine Elektricitäts-Gesellschaft intend to erect a central electricity station at Ober-Schönheide, on the Upper Spree, to supply current for lighting and power purposes to the villages in the neighbourhood.—A municipal committee at Munich have under consideration the designs for electric street lamps. Work has been commenced in connection with the erection of the municipal electric light station.—Several schemes have been submitted for the proposed electric lighting of Haynau.—At Dortmund the question of establishing a central station is again being discussed.—A central station is to be erected near Gersthorfen, having 6,000 h.p., for supplying current to Lugsburg and its suburbs.—The local authorities of Posen have appointed a committee to enquire into the matter of the erection of a central electric light station. Offers have been received from Messrs. Siemens and Halske, from the Helios Company, and from the Union Company. The last also proposed to convert the horse tramway into an electric line.—Messrs. O. L. Kummer and Co., of Niedersedlitz, have obtained the contract for the municipal electricity station at Niederlössnitz, near Dresden.—A committee of the Görlitz Municipality have visited Dresden and Chemnitz in order to inspect the electricity stations there, with a view to the adoption of the electric light at Görlitz.—The question of the introduction of the electric light at Blankenese, a watering place near Hamburg, is under consideration.—In future the Hanover municipal central station will replace consumers' incandescent lamps.—A deputation from the Plön Municipality have visited the electric light installation which has been carried out by Messrs. Max Schorch and Co. at Kappeln, with a view to the introduction of the light in their own town.—The newly-erected central station at Riedlingen, which has been erected by Mr. W. Reisser, of Stuttgart, is giving every satisfaction.—Mr. Kosch, a factory owner at Lautenburg, proposes to establish at his works a central electric light station to supply the town. Water power is available, and operations will be commenced next year.—Applications have been received for 4,500 incandescent lamps by the Stuttgart municipal electricity works.—The management of the Brunswick municipal gas and water works have enquired into the extent of the local electric lighting. They found that there were 27 isolated plants with 284 arc lamps and 4,988 incandescent lamps; seven block stations with 160 arc lamps and 3,537 incandescent lamps; the Court Theatre installation with seven arc lamps and 2,350 incandescent lamps, and the installation at the principal railway station with 14 arc lamps and 11 incandescent lamps.—A number of private electric light installations is projected at Dortmund.—Mr. Guttach has projected an electric lighting scheme for part of the town of Elbing.

The Block Telegraph.—The telegraph and signal superintendents of the Caledonian Railway Company have, says the *Glasgow Herald*, made an interesting addition to the existing system of block working. At present, block working is carried out on all our railways, but admittedly in such a way that a signalman is liable to make an accident at any moment by a mere slip of memory. When the improvements mentioned have been effected, however, accidents of this kind will be well-nigh impossible. The Caledonian block telegraph, like that of several other companies, consists of an instrument with miniature arms, corresponding to the signal arms on the outdoor starting signals. When a train is ready to proceed from section No. 1 to section No. 2, the signalman at No. 1 gives what is known as the "Be ready" signal on the warning bell, and if the section between No. 1 and No. 2 is clear the signalman at No. 2 responds by pressing a plunger, which electrically lowers the miniature signal arm on the block instrument at No. 1 box. The train may then proceed, and signalman No. 1 announces its departure by bell to signalman No. 2, who responds by pressing a second plunger, which electrically raises the miniature signal arm in cabin No. 1 to the danger or "protection" position. That this system of working is very simple the inventors have recollected, with the result that the efficiency of the "block" has been increased without in the least affecting the simplicity of the method by which it is controlled. The new appliances will effectually interlock the block telegraph and outdoor signals. The innovation has been made at the request of the chief officers of the company, chiefly for the new underground railway; and a condition was that no more detail should be introduced, as it was undesirable to change the work of the signalmen. The outdoor starting or controlling signal will be constantly locked, unless when permission has been obtained to send on a train to the next section. Signalman No. 1 will give the "Be ready" signal on the bell; signalman No. 2 will then (if clear) lower the miniature signal arm in No. 1 cabin by pressing his electric plunger, which will also release an electric coil on the starting signal at No. 1 section. Signalman No. 1 may then draw his starting signal (which hitherto was electrically locked) and allow the train to proceed, notifying to No. 2, of course, that the train has left, and the latter will press a second plunger which will raise the miniature signal arm in No. 1 box to danger, and at the same time effectually lock the starting signal there. No. 1 is now "locked up"; he cannot bring out another train, for his signal is immovable until No. 2 releases it. No. 2 repeats the bell signals to No. 3, and once the train has passed from No. 2 to No. 3 signals back to send on the second train. But as long as the first train is standing in No. 2 section it is an utter impossibility for the signalman to signal "Line clear" back to section No. 1, for his plunger is electrically locked till the first train passes into No. 3. Outside each starting signal will be a treadle fixed into the web of the rail, which, touched by the engine, electrically relieves the plunger in No. 2 box, and allows the signalman there to signal back "Line clear" to No. 1, provided, of course, No. 2 has first thrown his starting signal to danger. In ordinary block working a signalman may give "Line clear" by mistake, but under the new mode such an error will be impossible, for the train itself will practically control both block and signals.

Digitized by Google

THE ELECTRICITY WORKS AT CARDIFF.

General Remarks.

The town of Cardiff, famous for its shipping trade, is situated at the mouth of the River Taff and on the estuary of the Severn. Having an enterprising Corporation, the welfare of the town has been studied and promoted in almost every direction. The principal streets are broad and well kept, and the town enjoys exceptional facilities in regard to railway and steamship accommodation.

The town, which has a population of 150,000, is in a prosperous condition, which has been largely contributed to by the abundance of minerals in the district. It may be said that of the leading local industries the shipping trade stands first, and the docks now cover an extensive area. Next in importance come the iron foundries, tin-plate works, and iron shipbuilding yards. The exports of coal and iron from the port are among the most important in the country. The public buildings are situated in St. Mary-street. A relic of olden times is afforded by Cardiff Castle, now the property of the Marquis of Bute. It was originally established in 1080, but it has been restored, and presents a handsome and attractive appearance.

Preliminary Steps in Electric Lighting.

As long ago as 1890 the Corporation of Cardiff had under consideration the subject of introducing a municipal supply of the electric light, and, as in many other towns, it was some time before any definite decision on the matter was arrived at. About that period Mr. W. H. Massey, M.I.C.E., M.I.E.E. (of the firm of Messrs. Massey and Allpress, 25, Queen Anne's-gate, Westminster, S.W.), was called in as consulting engineer by the Corporation. A sub-committee—comprising Mr. P. W. Carey, Mr. Lascelles Carr, Mr. J. L. Wheatley (town clerk), and Mr. W. Harpur, M.I.C.E. (borough engineer)—was appointed to accompany Mr. Massey on visits of inspection to various central electric light stations in England, France, Belgium, and Germany.

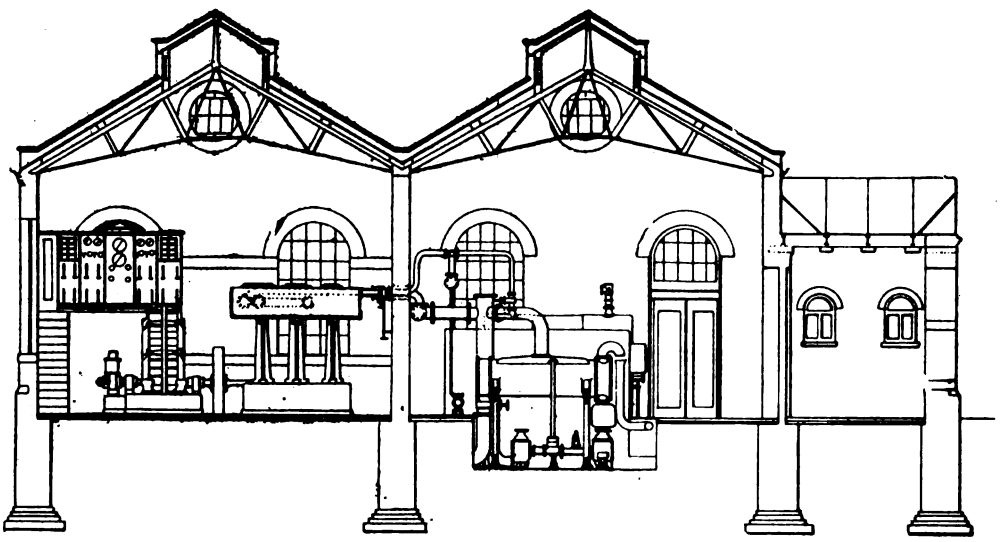
The Corporation obtained a provisional order on July 3, 1891, and it was for the purpose of deciding upon the best method of carrying out the powers thereby conferred upon them that they authorised the committee mentioned to fully investigate different systems of electric supply and to report thereon.

The committee subsequently drew up a preliminary report, which was published in the *Electrical Engineer* on December 11, 1891. The conclusion was that they "had not yet seen anything which they could recommend the Corporation to adopt without modification." Appended to the report was a statement by the borough engineer that the then cost of lighting by gas the streets comprised within the compulsory area stipulated by the provisional order amounted to £650 per annum, and that to light those streets partly by gas and partly by electricity would reach an annual sum of £948.

Subsequently, as will be seen on referring to the *Electrical Engineer* of August 19, 1892, two further reports were drawn up by the committee, who, acting upon the advice of Mr. Massey, recommended the adoption of the high-pressure alternating-current system of generation, with distribution from transformer-chambers on the low-pressure method. A casual glance at the map of Cardiff will show the scattered nature of the district, and this fact, combined with the impossibility of securing, except at a price which was prohibitory, a site for the erection of the station near the centre of the town, fully justified the recommendation of the committee, who suggested that as soon as the question of site was determined the consulting engineer should be instructed to prepare plans and specifications for the carrying out of the undertaking.

The Adopted System.

To the credit of Mr. Massey, be it said that a long time previous to the formation of the sub-committee he had suggested that the Corporation should lay down high-pressure alternating-current plant, and that rectifiers should be introduced for converting the alternating current into direct current for public arc lighting. In fact, he was the first in this country to recommend the employment of rectifiers in connection with central-station work.



Cardiff Electricity Works.—Cross-section of Engine and Dynamo Room and Boiler House.

Ultimately the recommendations of the consulting engineer were adopted by the Corporation, and the central station recently set in operation is the result. The Cardiff station possesses two decidedly novel features. One is the fact that the use of rectifiers was here specified for the first time in this country, and the other is the introduction of vertical triple-expansion condensing engines, fitted with separate cut-off gear for each cylinder.

The control of the work in connection with the generating station has been in the hands of the Electric Lighting Committee of the Corporation, the present members of which are:

LIGHTING AND ELECTRICAL COMMITTEE.

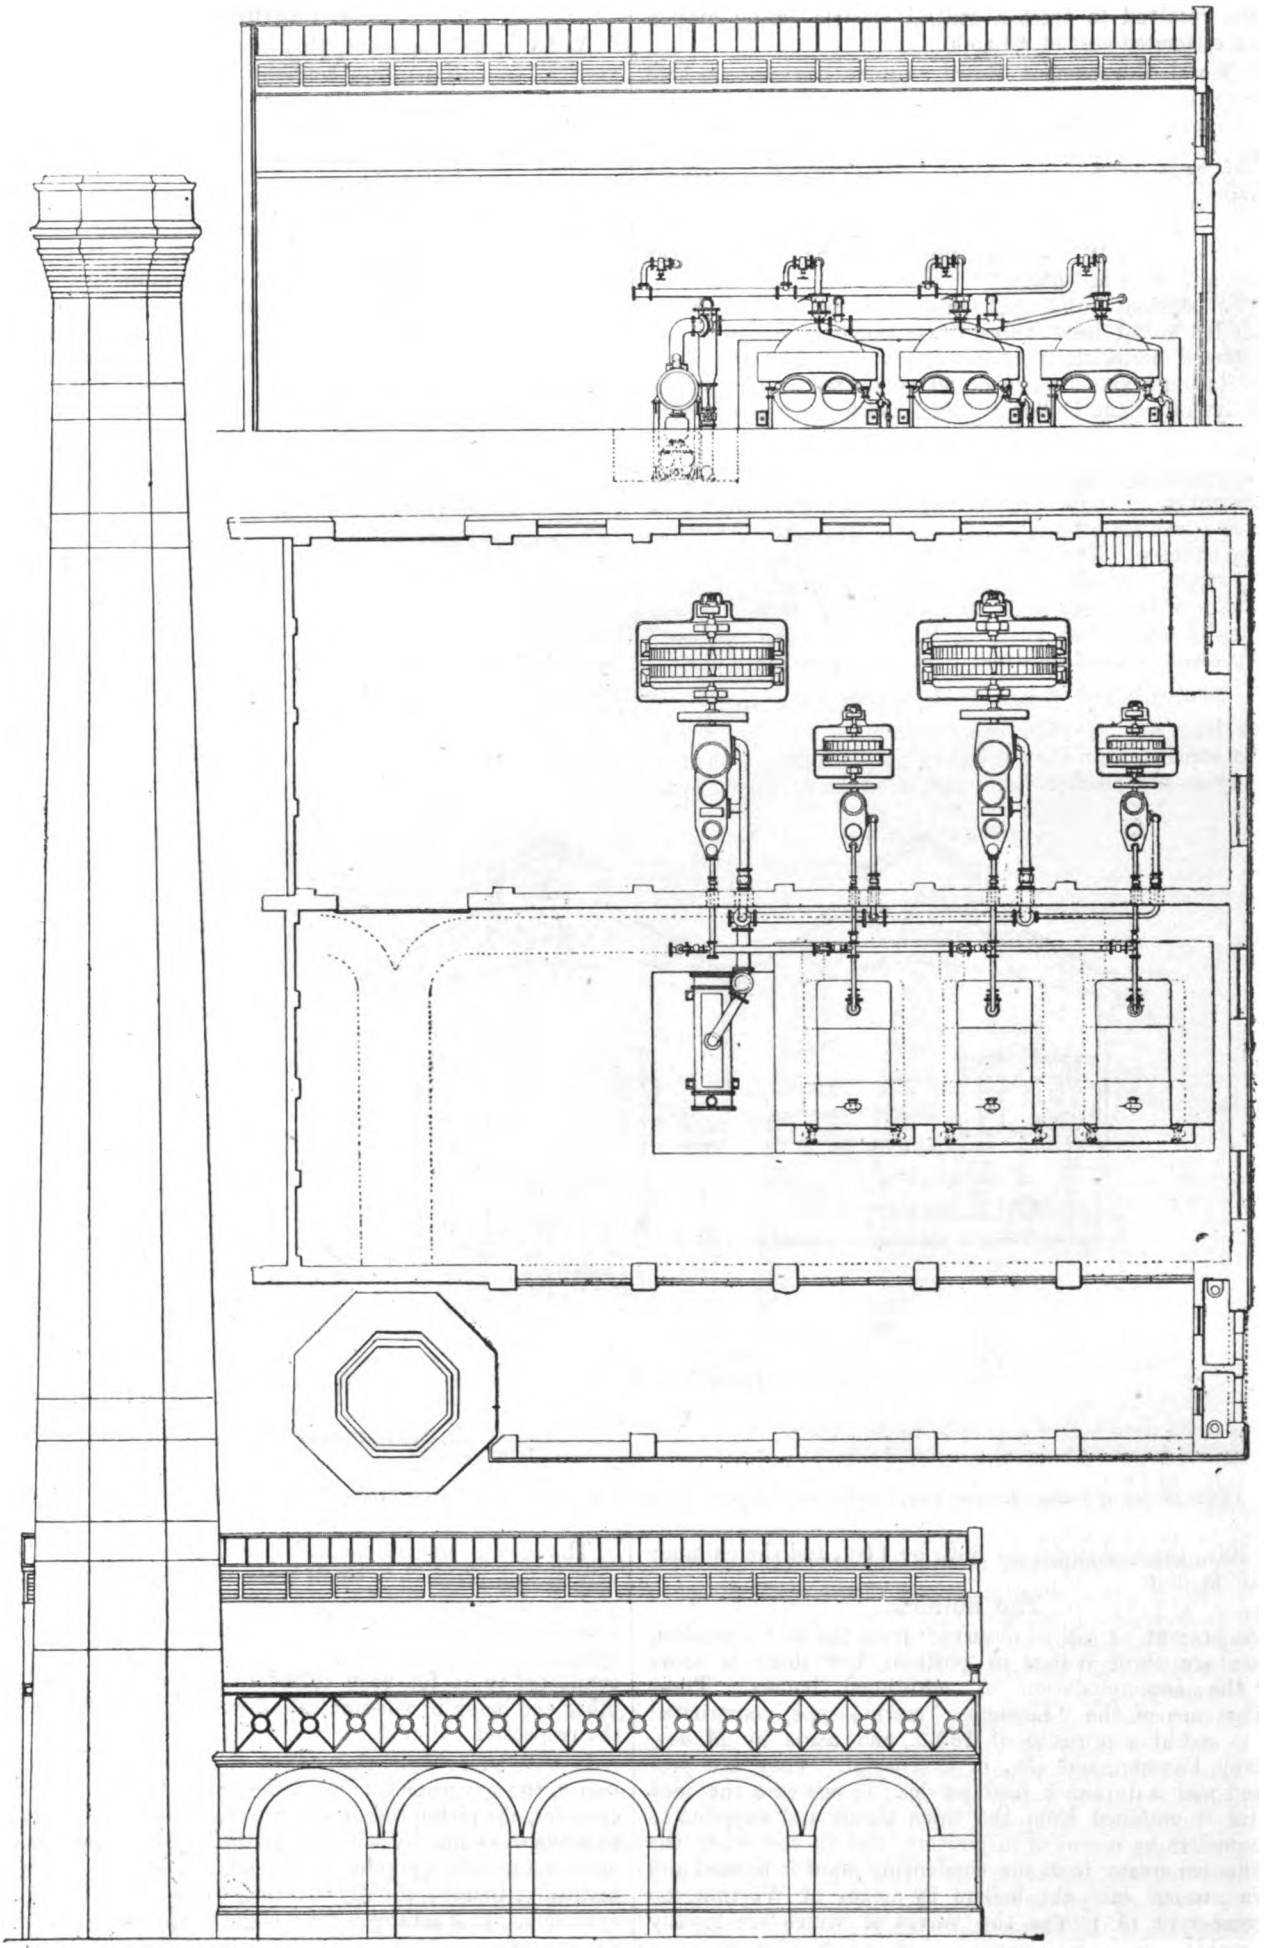
ALDERMAN P. W. CAREY, MAYOR (DEPUTY CHAIRMAN).

COUNCILLOR W. E. VAUGHAN (CHAIRMAN).

ALDERMAN LEWIS.	COUNCILLOR E. W. SHACKELL.
,, T. WINDSOR JACOBS.	,, J. H. CORY.
,, ANDREW FULTON.	,, WM. EVANS.
COUNCILLOR RAMSDALE.	,, B. JOHN.
,, S. A. BRAIN.	,, A. GOOD.
,, T. H. RICHES.	,, G. BENYON HARRIS.

The Corporation eventually decided to erect the station on municipal land on Canton Common in the south-western part of the town. The site adjoins the Great Western Railway at the extreme end of Eldon-road, and a siding from the main line into the works allows of coal being

Digitized by Google



Cardiff Electricity Works.—South Elevation of Station Building, Elevation of Boilers, and Plan showing General Arrangement of Plant.

readily obtained at economical rates. Plans and specifications were accordingly prepared by Mr. Massey, Mr. W. Harpur, M.I.C.E., being responsible for the architectural features of the building, and being joint engineer with Mr. Massey for carrying out the scheme. The land available being admirably arranged for future extensions,

Digitized by Google

it was resolved to erect a central electric supply station at an estimated cost of £32,500.

A Local Government Board enquiry having been held into the application of the Corporation to raise money for the purpose of fulfilling the requirements of the provisional order, tenders were invited for the execution of the work, that of Messrs. Thomas and Co., of Cardiff, being accepted for the construction of the buildings, and that of Messrs. Siemens Bros. and Co., Limited, of Queen Anne's-gate, Westminster, S.W., for the supply of the whole of the steam and electrical plant.

The station buildings, which are capable of being extended to at least three times their present size, are illustrated herewith, together with a portion of the plant. The station covers a space of 80 square feet. The engine and dynamo room is 80ft. by 30ft., the boiler-house is 80ft. by 30ft., the coal-stores are 60ft. by 14ft., and the chimney is 150ft. high.

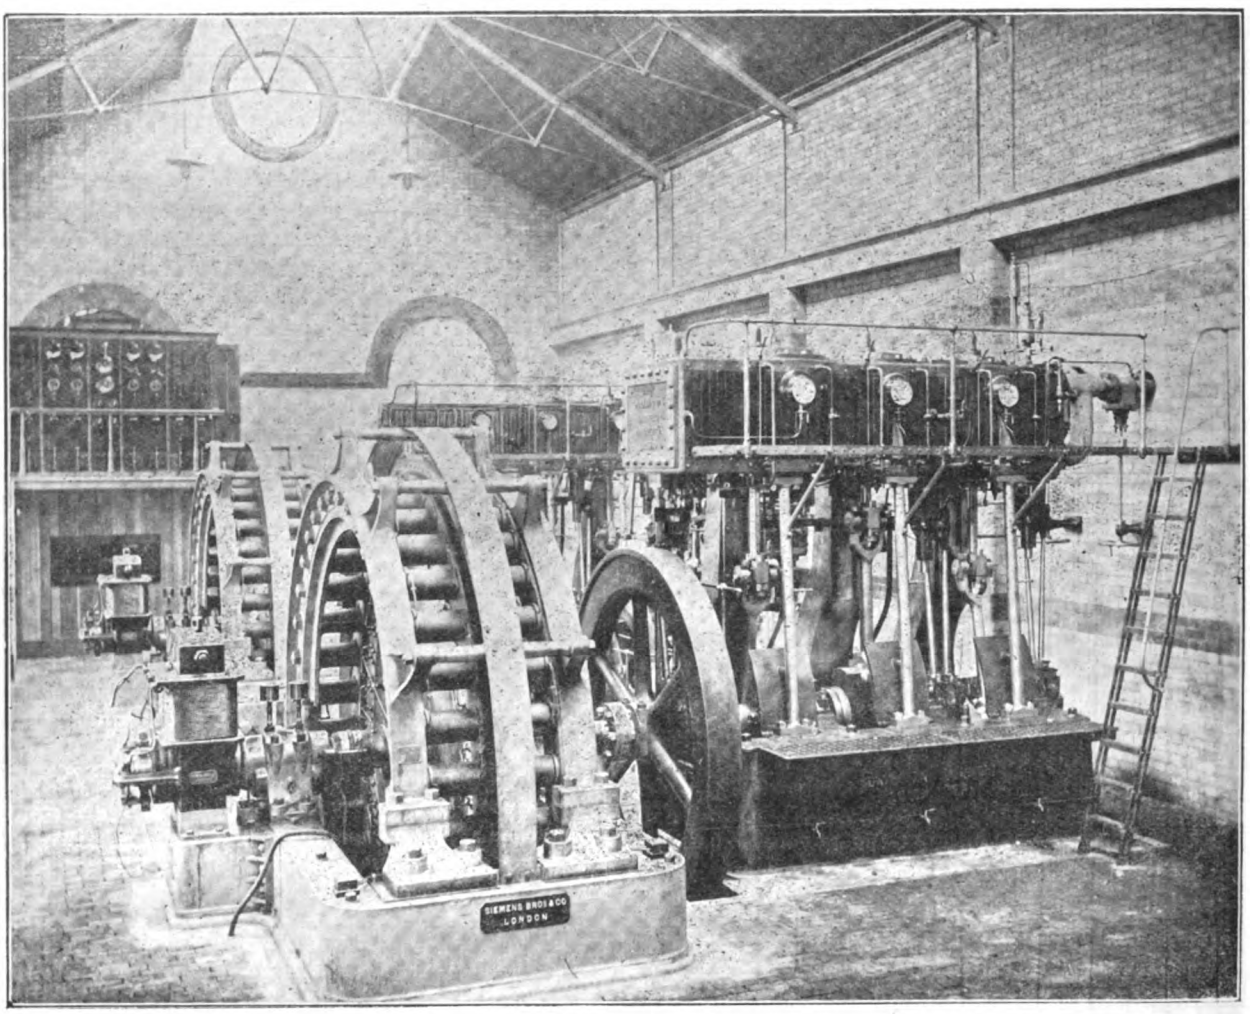
The Boilers.

At present, as will be observed from the end elevation, there are three boilers in position, but there is room for the accommodation of additional boilers. These boilers are of the "Economic" marine type, constructed for a working pressure of 160lb., and made by Messrs. Davey, Paxman, and Co., of Colchester. They are provided with a duplicate feed service; in one case the feed water is obtained from the town mains and supplied to the boilers by means of inspirators, and in the other, the condensed steam from the condensing plant is filtered and then pumped into the boilers by means of Worthington marine type of pumps, the valves of which are readily accessible. A further supply of water is afforded by a tank arranged on the roof of the coal-stores for the collection of rain-water. The main steam pipes and branches, which are carried into the engine-room through the wall of the boiler-house, are all of copper, as is also the exhaust main. The arrangement is shown on the general plan.

The Engines.

As far as we remember, this is the first town for which vertical triple-expansion condensing engines were recommended for central-station work—at all events, in this country. Mr. Massey is a firm believer in this type of engine, which he says ought to be very nearly as economical on light as on full loads.

The novel feature of the engines lies in the fact that they were specified to be equipped with cut-off gear to each of the cylinders, so that on variable loads the work could be evenly distributed between the cylinders. These steam motors were made by Messrs. Davey, Paxman, and Co., of Colchester, who finding that the engines would not be required by the appointed time, took the opportunity of experimenting with the gear, and succeeded in making it to be automatically controlled by the governor.



Cardiff Electricity Works —Internal View, showing line of Siemens Alternators and Exciters, and Davey-Paxman Triple-Expansion Condensing Engines.

The arrangement is somewhat as follows: The governor acts upon a piston in a small horizontal steam-cylinder, one end of the piston-rod being connected at right angles with a horizontal shaft carried along the front of one side of the cylinders. At right angles to this shaft there is rigidly connected to it for each cylinder one end of a rod, the other end being in communication with the cut-off gear for the respective cylinders.

It will be evident that when the load on the engine varies, the governor acts upon the small horizontal steam-cylinder, the piston-rod of which causes the horizontal shaft to move in sympathy with the piston, thus causing the cut-off gear on each cylinder to act simultaneously and automatically, thereby equally dividing the work between the cylinders. This arrangement has so far admirably answered its purpose.

There are altogether four engines. Two of these are vertical triple-expansion condensing engines, each of 270 b.h.p., and running at a speed of 133 revolutions a minute. The other two engines are of the vertical compound type, each of 65 b.h.p., and making 200 revolutions

Digitized by Google

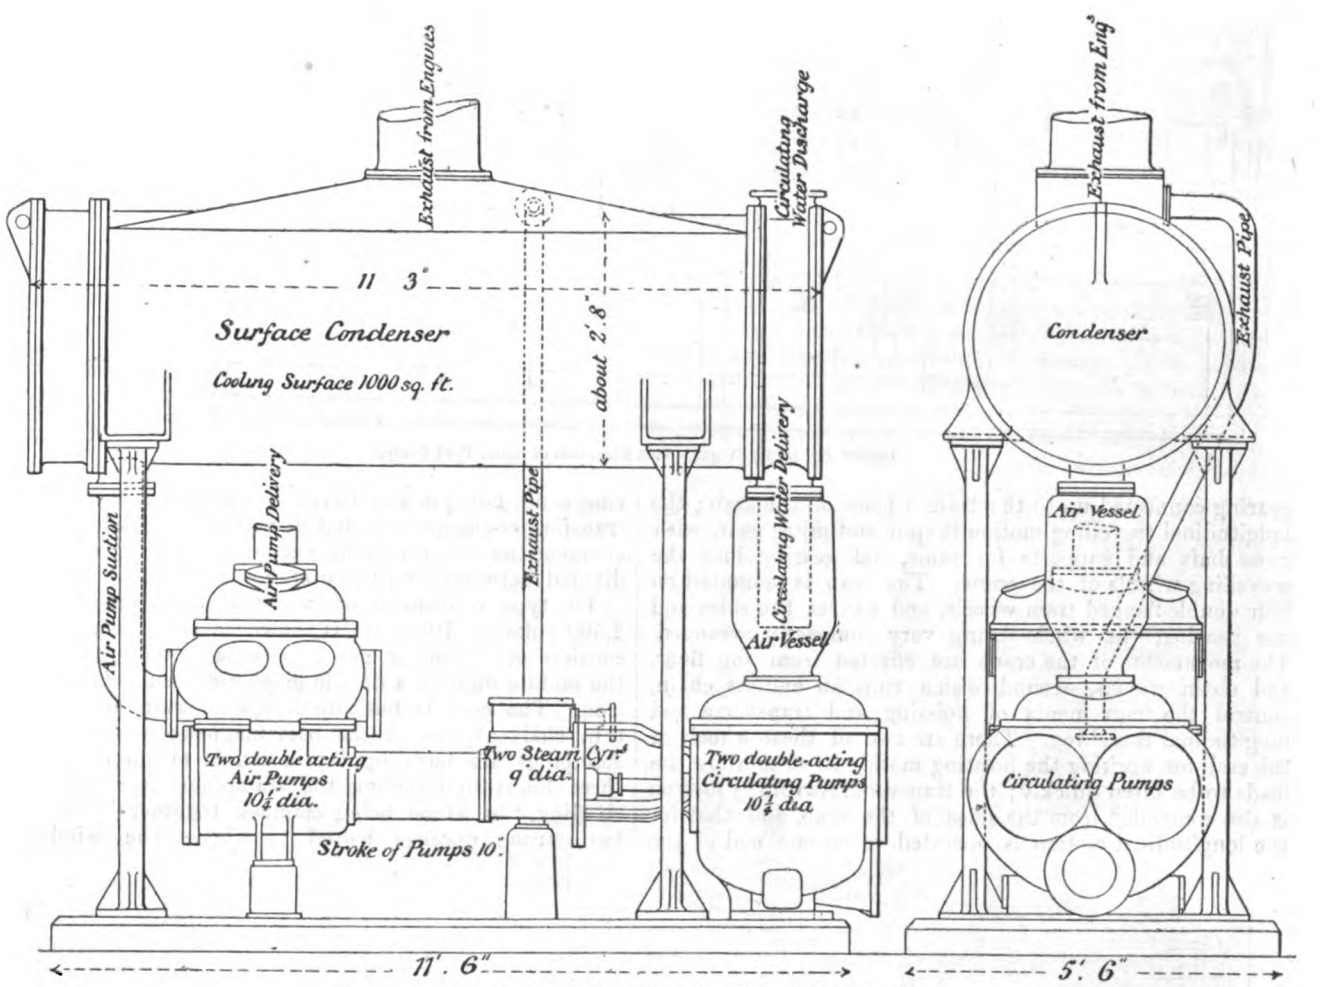
per minute. All these engines are for direct-driving the alternators.

The Condensing Plant.

The exhaust steam from the engines passes along the branch pipes into the copper exhaust main previously mentioned. It is then delivered into the condenser, or, if it be desired for any reason or other to disconnect the latter, the exhaust steam, by means of a valve, is allowed to pass into the atmosphere through the chimney. The condensing plant, of which illustrations are annexed, has been made by Messrs. J. Watt and Co., of Soho Foundry, Birmingham. It comprises a vertical surface condenser, having 1,000ft. of tube service, combined with duplex double-acting air and circulating pumps, the latter being capable of raising 25,000 gallons of water per hour a height of 15ft. The condenser is capable of maintaining a vacuum of 13½lb. per square inch in the exhaust pipes.

corresponding alternators, made by Messrs. Siemens Bros. and Co., Limited, of Westminster, S.W. One of the features of the two large alternators, which each give 72 amperes at 2,500 volts, with a periodicity of 40 per second, is their size; they have revolving disc armatures having a diameter of something like 13ft., which is probably the greatest diameter of any Siemens alternator introduced in this country, although we believe that in Germany larger machines have been installed. The exciters for these alternators, which are provided with water-jacketed bearings, are coupled direct to an extension of the armature shafts, so that each direct-coupled set comprises engine, alternator, and exciter. These two exciters have drum armatures, and each give 100 amperes at 45 volts.

The two smaller alternators, which are direct coupled to the compound engines already mentioned, each furnish 16 amperes at 2,500 volts; their exciters, which are



Cardiff Electricity Works.—End and Front Elevations of Condensing Plant.

The suction of the circulating pumps is connected to a large well or pond arranged on land outside the station building, and the delivery conveying away the water that has been passed through the tubes is in communication with an open trough and channel, leading the hot water back to the well by a circuitous path. The course pursued by the water is such that on reaching the well, where it becomes mixed with the natural supply therein rising, the water is sufficiently cooled to be again used for condensing the exhaust steam.

The air-pump suction is in communication with the condenser, and its delivery is connected to a series of tanks provided with filtering arrangements for removing the oil from the condensed steam. The hot water is then passed into a well, and from thence is supplied to the boilers by Worthington marine type of feed-water pumps, made by the Worthington Pumping Engine Company, of Queen Victoria street, E.C.

The Alternators and Exciters.

As already mentioned, the system of direct driving has been adopted. The four engines are coupled direct to

also operated direct from the armature shaft, each give 65 amperes at 45 volts.

The Switchboard Arrangements.

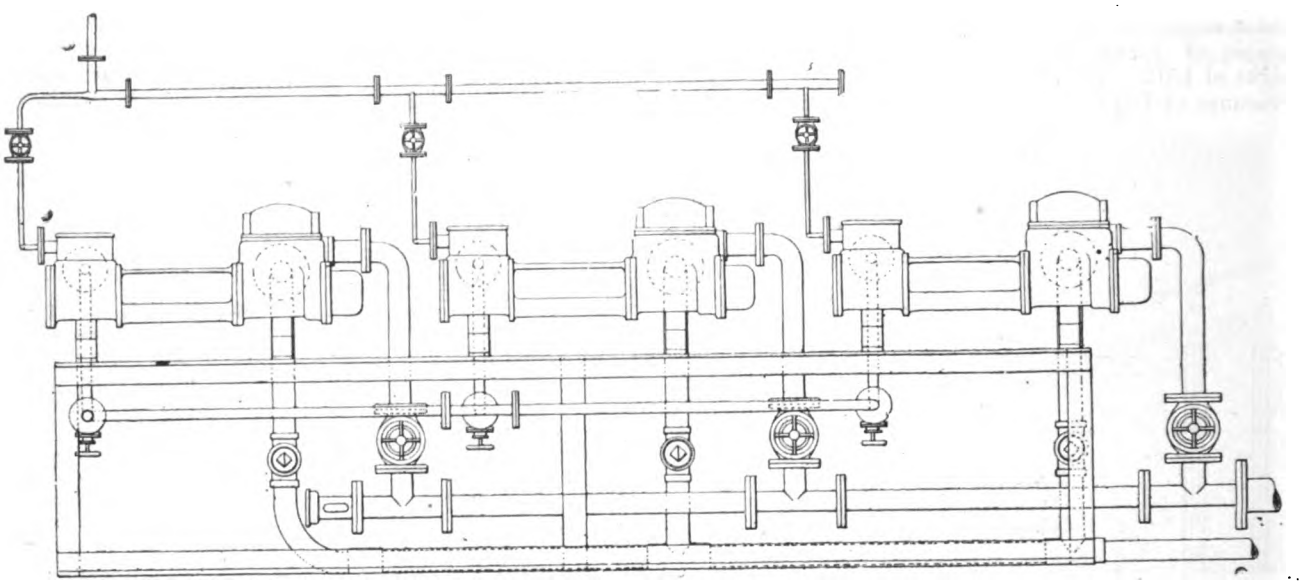
The switchboard, which is erected on a gallery at one end of the engine and dynamo room, as illustrated in the internal view of the station, is so arranged that any one or more of the four alternators can be connected either separately or together to any one or more of four feeder mains. At the present moment, however, only two feeders, to which reference will again be made, have been laid down. The switchboard, supplied by Messrs. Siemens Bros. and Co., comprises five panels. The first is the "commutator" panel, the second is for the two large alternators, the third for synchronising purposes, the fourth for the two smaller alternators, and the fifth is a spare commutator board for additional machines and the two further feeders.

The alternator panels are provided with double-pole fuses, main and field switches, and voltmeters and ammeters. The object of the commutator panel is to connect any alternator to either feeder. This is accomplished by means of plugs. The return is to the omnibus bar of a

Digitized by Google

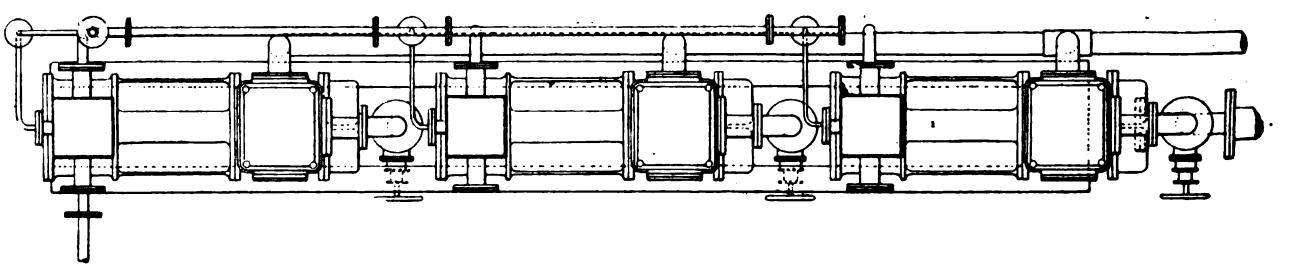
"return board" near the floor, this bar being put to earth.

An overhead travelling crane, having a capacity of 10 tons, is arranged in the engine-room. This crane, which has been made by Mr. Thomas Smith, of Old Foundry, Rodley, near Leeds, has a span of 29ft. The hoisting gearing is single and double purchase, so as to suit varying loads, and the chain and the drum are made to suit the height of lift. The crane, which is similar to that shown in the illustration, is provided with a powerful friction brake and a safety catch, so as to prevent the load running down suddenly. The transverse travelling motion is spur



Cardiff Electricity Works.—Side Elevation of Boiler Feed Pumps.

gearing connected up to the tram wheels of the crab; the longitudinal travelling motion is spur and mitre gear, with cross-shaft and supports for same, and gearing into the travelling wheels of the crane. The crab is mounted on four double-flanged tram wheels, and carries the sides and the gearing, the whole being very compactly arranged. The movements of the crane are effected from the floor, and chain wheels, around which runs an endless chain, control the movements of hoisting and transverse and longitudinal travelling. There are two of these wheels of the crab for working the hoisting motion so as to allow the loads to be lifted quickly; the transverse travelling motion is also controlled from the sides of the crab, and that for the longitudinal motion is operated from one end of the



Cardiff Electricity Works.—Plan of Boiler Feed Pumps.

beams. The transverse beams are of English steel rolled joists and steel channel end carriages, with brackets and caps for the axles, which are of steel, keyed to the four double-flanged travelling wheels.

The Feeder and Distributing Mains.

As already mentioned, there are two high-pressure feeder mains. These are of the Silvertown concentric type, made by the India Rubber, Gutta Percha, and Telegraph Works Company, of Silvertown, E. These concentric feeders have a specially thick insulation, the conductors being respectively equal to $^{7}/_{16}$, $^{19}/_{16}$, and $^{19}/_{14}$, insulated pure, then vulcanising indiarubber, next sheathed with return conductor of tinned copper wires, further insulated pure and vulcanising indiarubber, and the whole vulcanised together, braided, and extra taped over all. They are laid in the ground in two 3in. iron spigot and socket pipes, and two additional pipes have been put down to receive other feeders as occasion arises.

The feeders are brought into the centre of the town to six transformer stations arranged under the pavement, a branch being taken into the basement of the Town Hall for the street-lighting. These transformer-chambers consist of cast-iron boxes 3ft. square and 6ft. deep, each containing a 40-kilowatt Siemens transformer. From each transformer-chamber a pair of $^{37}/_{14}$ Silvertown "Y" type of single low-pressure mains, placed direct in the ground, is carried in either direction. These distributing mains do not form a ring main, but junction-boxes are provided between each transformer-chamber, so that in case of a breakdown in any chamber the latter may be cut out and the load equally divided between the two outer transformers.

The type of transformer adopted, which converts from 2,500 volts to 105 volts, is shown in the illustration. It consists of a primary and a secondary winding enclosing the middle limb of a double magnetic circuit of laminated iron. The core is built up of special stampings of very thin charcoal iron of the best magnetic quality. These stampings are built up into a double magnetic circuit of three limbs by inserting the stampings into the finished winding, the whole being clamped together by means of two strong castings bolted together. The winding is arranged on a substantial bobbin, the body of which is made entirely of insulating material and the cheeks of wood. The material being of a specially tough character, it will retain its mechanical and insulating properties at the highest temperature to which the transformer can rise when running continuously at full load. In the high-pressure coil a layer of the same material is inserted between successive layers of wires. The winding consists of turns of high-conductivity copper wire, either double-cotton covered or taped. The high-pressure terminals are insulated from the wooden cheek of the bobbin by means of ebonite, whilst the low-pressure terminals are mounted on the wood.

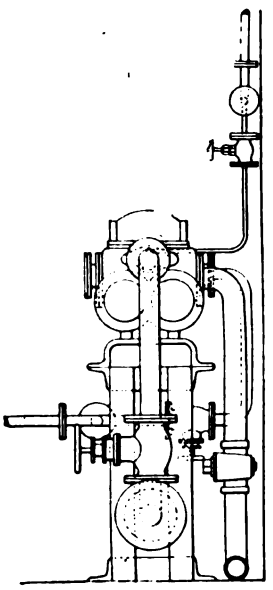
With a view to prevent the accumulation of explosive gases in the transformer and junction boxes, the wise plan has been adopted of connecting these with ventilating pipes

Digitized by Google

carried up the sides of the nearest buildings. This is believed to be the first occasion of the practical adoption of this method of ventilation in this country.

Public Lighting.

So many complaints have been made regarding the public illumination of some of the main thoroughfares, as, for instance, St. Mary-street, High-street, Castle-street, Duke-street, Queen-street, etc., that a few words of explanation are due, not only for the consulting engineer,



Cardiff Electricity Works.—End Elevation of Boiler Feed Pumps

but also for the contractors. It is all very well for those persons who have no knowledge of the true state of affairs to throw upon an apparatus or individuals the blame for any inefficient street illumination that may occur with arc lamps whether energised from high-pressure direct-current machines, alternators, or rectifiers. But when the correct position is ascertained, and the responsibility for such defective lighting has been located, sympathy should be expressed with those who have been wrongly complained of. The former has been and the latter should be the case at Cardiff. As a matter of fact, the lighting of the streets, which it will be remembered was begun two or three weeks ago, was ordered by the Corporation to be commenced before the arrangements for this branch of the service had been completed at the central station, and, of course, the result was only what might have been expected. Mr. Massey, who had not sanctioned the switching on of the arc lamps, pointed out to the Corporation the adverse opinions that would be entertained by a continuation of the public illumination until everything was finished at the generating station. The Corporation wisely adopted this advice, and the experimental street-lighting was discontinued.

As, however, the whole of the arrangements at the central station and at the rectifier sub-station at the Town Hall are now practically completed, a fresh start with the arc lamps is on the point of being made, and we have no doubt as to the result. In fact, so confident are the Corporation on the subject of public arc lighting, that considerable extensions have already been decided upon.

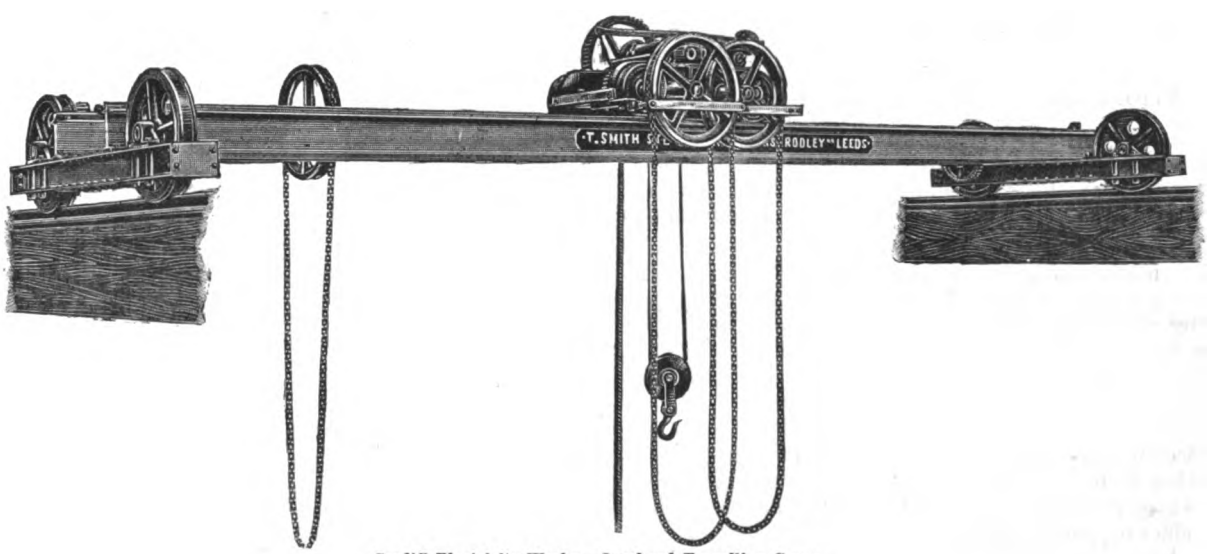
The arc lamps, which are of Siemens make, are arranged on iron standards made by Messrs. MacFarlane and Co., of Glasgow, the height from the street-level to the centre of the arc being 22ft. The lamps are provided with lanterns glazed with cathedral glass, similar to those in the City of London. Wherever possible, the standards have been erected on refuges in the centre of the thoroughfares, but where the streets are too narrow for this the lamps are arranged on the side of the footpaths.

The arc lamp pillars are made of cast iron and in a characteristic design, the ornamentations and mouldings being beautifully realised in a chase and effective style. A door, bearing the Cardiff coat of arms, is provided in the base so as to give access to the conductors and switches. The pillars are fixed into the ground by a tail-piece 3ft. 6in. long.

The Rectifiers.

It is, of course, understood, generally speaking, that an alternating current is produced in a direct-current machine, and that by the use of a commutator the current is "re-dressed," and becomes a continuous current. Now, in the case of the Cardiff central station, it may be said that an alternating current is produced at the works, and that the commutator, instead of being put there, is installed at the Town Hall, a mile and a quarter distant, and that at the latter place the process of commutation is effected. In fact, a rectifier, or motor commutator, as some prefer to call this type of converter, consists of a small synchronous motor driving two commutators.

The rectifiers, of which two have been arranged in a temporary sub-station in the basement of the Town Hall (with a third now being installed as a reserve), are of the Ferranti type, made by Messrs. S. Z. de Ferranti, Limited, of Charterhouse-square, E.C. These rectifiers together are capable of energising 48 12-ampere arc lamps in series,



Cardiff Electricity Works.—Overhead Travelling Crane.

each apparatus supplying two circuits of 12 lamps each. The lamps are arranged on alternate circuits, so that in case of a breakdown of one circuit every other lamp is still able to maintain a supply of light, although the main object in view is to keep the E.M.F. down to 600 volts.

The rectifiers, or motor commutators, each consist of a small self-starting, single-phase synchronous motor, having a low-pressure commutator for commuting the current required to excite its own field magnets. The motor armature shaft is supported in four long bearings, which are fitted with ring oiling gear. At each end of the arma-

Digitized by Google

ture shaft a high-pressure commutator is fitted, each of which rectifies the current for one arc light transformer and for one circuit. The high-pressure commutator brushes are held in a concentric frame, which can be rotated to the best position of commutation. A double-pole reversing and cut-off switch for changing over and breaking the connections from the arc light transformer is arranged in each circuit, whilst a special water-break switch is fitted in the primary of each arc light transformer for the purpose of switching on the lamps gradually, and thus preventing a flickering on the incandescent lighting, which might happen if a circuit of 12 lamps were switched suddenly on the small machine.

The motors are run off two small transformers, transforming from 2,500 to 100 volts, and they are enclosed in heavy cast-iron cases, and are fitted with double-pole high-pressure and low-pressure fuses. There are four Ferranti constant-current arc light transformers, each of 10 units capacity, and constructed for giving a fixed current of 12 amperes on the secondary, the high-pressure side of the converter being fed direct with 2,500 volts.

Private Lighting.

Partly owing to unforeseen delays that have occurred in the completion of the station, and partly because of the approaching termination of the year, the Cardiff people have manifested considerable apathy in becoming users of the electric light. At present, however, the tendency is improving, and the largest load on the station has been between 600 and 700 40-watt lamps, whilst further applications for a supply are now being constantly received.

The price of gas, which is furnished by a company, is 2s. 10d. per thousand. At this rate Cardiff shopkeepers, hotel proprietors, and householders should find it advantageous to substitute the electric light for gas, seeing that by a judicious use of switches in turning out lamps not required, the cost of the former can be practically brought down to that of the latter, whilst at the same time the electric light is far superior.

It will be seen from the foregoing description that the Cardiff Corporation have embarked upon an undertaking possessing some novel features, the working out of which in practice will be watched with considerable interest by electrical engineers. The station has been well designed, and the Corporation, the consulting engineer, and the contractors are to be congratulated on the result. It only remains for us to wish prosperity to the station.

REGULATIONS FOR THE SUPPLY OF CURRENT BY THE CARDIFF CORPORATION.

The Cardiff Corporation issued in September a pamphlet giving particulars for the guidance of intending users of the electric light. The following are extracts from the *brochure*:

"The supply mains will be brought into the consumer's premises and up to a pair of cut-outs, which will be provided by the Corporation, and will be placed at a point chosen by the borough engineer; and this work will be carried out free of cost to the consumer, provided that the length of such branch mains does not exceed 60ft., but for any greater distance special terms will be arranged. The price for current by meter will be 6d. per Board of Trade unit—that is, 6d. per 1,000 watt-hours—so that a 40-watt lamp, which will give a light of 10 to 14 candles according to the efficiency of the particular make of the lamp, may be run for $\frac{1000}{40} = 25$ hours for 6d.—say a farthing per lamp per hour. This is about 50 per cent. more than gas lighting by the ordinary 5ft. burner, if the cost be compared lamp per lamp and hour per hour; but by the judicious use of switches which enable consumers to turn out lamps when not absolutely required, the cost of electric light can in an average dwelling-house be brought down to less than the amount previously paid for gas."

The pamphlet, whilst suggesting that consumers should enter into agreements for the supply of electrical energy for a period of at least three years, leaves it open to them in the form of agreement to state what period of years they are willing to become clients of the electricity works. The conditions of supply are briefly as follow.

"The Corporation shall provide, free of cost, a main cut-out and two terminals for supplying the electrical energy to the consumer's premises, and also a suitable meter for measuring the energy supplied. The apparatus thus provided by the Corporation shall be placed in a convenient position on the consumer's premises, accessible at all reasonable times to the servants of the Corporation, and no alteration shall be made in such position except by agreement, and at the cost of the party requiring the change. The apparatus thus provided by the Corporation shall remain their property, and the consumer shall pay a rental for the same, according to the following scale, on the periodical days hereinafter appointed for payment of the energy supplied.

"Meter: For every 100 lights, 8 c.p., or proportion of same, £1 per annum. Cut-outs and terminals: For 8-c.p. to 16-c.p. lamps, up to 25 lights, 5s. per annum; above 25 and up to 50 lights, 10s.; exceeding 50 and up to 100 lights, 15s.; above 100 and up to 150 lights, £1; exceeding 150 and up to 200 lights, £1. 5s.

"The Corporation will make the necessary connections with the service wires and meter and main cut-out at their own cost provided the run of branch mains does not exceed 60ft., but the cost of connecting to the internal wiring shall be borne by the consumer."

PRACTICAL NOTES ON DYNAMO CALCULATION.*

BY ALFRED E. WIENER.

(Continued from page 639.)

33. *Actual Field Density of Dynamo.*—According to the definition given in Section 31, the actual field density of a dynamo is the total useful flux cutting the armature conductors, divided by the area of the actual magnetic field—thus

$$\mathfrak{B} = \frac{\Phi}{A_f} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (93)$$

where $\mathfrak{B}$ = field density in lines of force per square inch;
Φ = useful flux, in webers, from formula (91) or (92) respectively; and
A_f = actual field area, in square inches—*i.e.*, area occupied by the effective armature conductors.

This actual field density (93) is, in general, slightly different from the original field density, selected from Table IV., Section 4, and used for the determination of the length of armature conductor, for the reason that, in practice, the length of the polar arc is not fixed with relation to exactly obtaining the assumed field density, but is dimensioned according to a construction rule having reference to the ratio of the distance between pole corners to the length of gap spaces (see Section 34).

It would be an easy matter to obtain the length of the polar arc and the percentage of its embrace from the assumed field density, for supposing that in a machine with smooth armature the length of the pole-pieces is equal to that of the armature core, we would simply have to make the sum of the lengths to the polar arcs of half the number of poles $= \frac{\Phi}{\mathfrak{B} \times l_a}$, or the percentage of the polar arc,

$$\beta = \frac{\Phi}{\mathfrak{B} \times l_a \times d_f \times \frac{\pi}{2}} \quad . \quad . \quad . \quad (94)$$

in which

β = percentage of polar arc, or quotient of sum of all polar arcs by circumference of mean field circle;
Φ = useful flux, in webers, from (91) or (92);
$\mathfrak{B}$ = assumed field density, in lines per square inch, from Table IV.;
l_a = length of armature core, in inches, formula (12); and
d_f = mean diameter of magnetic field, in inches, which is given by the core diameter of the armature, by the height of its winding space, and by the clearance between the armature winding and the pole-pieces: $d_f = d_a + h_a + k_{12}$ (see Section 34).

* From the *Electrical World* (New York).

Digitized by Google

But since the polar embrace so determined may not be within the limits of practical design in accordance with the construction rule referred to, it is advisable not to follow the process indicated by formula (94), but to fix the distance between the pole corners, and thereby the percentage, $\mathfrak{B}$, by that rule, and to calculate the actual field density corresponding to the same by formula (96) or (100) respectively.

This latter method is in no way objectionable, as the new actual value of $\mathfrak{B}$ only enters the calculation of the magnetomotive force, and the change does not affect any of the previous calculations concerning the dimensions and the winding data of the armature. For, according to formula (90), the same E.M.F. will be generated by a certain number of conductors moving at a constant speed as long as the total useful flux remains the same; the E.M.F. generated by a certain armature therefore remains constant as long as the product of field density and field area is kept at the same value, and it matters not whether this product is made up of the original field density and an area corresponding to the polar embrace found from formula (94), or of a larger actual density and a correspondingly reduced field area.

(*a*) *Smooth Armatures.* — In smooth-core armatures, Fig. 46, the area, A_f, occupied by the effective conductors, is obtained from

$$A_f = d_f \times \frac{\pi}{2} \times \beta' \times l_f \quad . \quad . \quad . \quad (95)$$

the actual field density, therefore, by inserting (95) into (93), can be found

$$\mathfrak{B} = \frac{\Phi}{d_f \times \frac{\pi}{2} \times \beta' \times l_f} \quad . \quad . \quad . \quad . \quad (96)$$

where $\mathfrak{B}$ = actual field density of dynamo, in lines of force per square inch;
Φ = total useful flux of machine, in webers, from formula (91), or (92);
d_f = mean diameter of magnetic field, in inches;
β' = ratio of effective field circumference, obtained from the percentage of polar embrace, β, by means of Table XXXII., Section 20;
l_f = mean length of magnetic field, in inches;
$l_f = \frac{1}{2}(l_a + l_p)$; l_a = length of armature core in inches;
l_p = length of pole-pieces in inches.

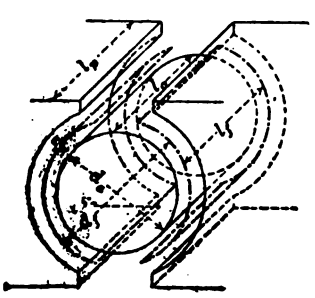


FIG. 46

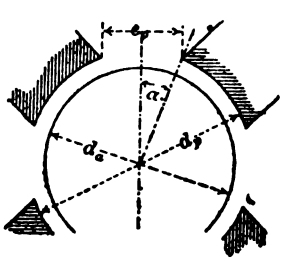

FIG. 47.

(*b*) *Toothed and Perforated Armatures* —For toothed and perforated armatures the area, A_f, occupied in the magnetic field by the effective armature conductors cannot be directly calculated from the dimensions of the armature core, since the path area of the actually useful flux cutting the conductors depends upon too many conditions as to be formulated satisfactorily, and it is therefore advisable to compute the actual field density, $\mathfrak{B}$, directly from the electrical data of the armature.

According to Chapter 1, the E.M.F. generated per foot of effective armature wire moving at a velocity of 1ft. per second in a field of the density of one line per square inch is $\frac{72 \times 10^{-8}}{b}$ volt, if there are b bifurcations of the current in the armature.

For the total effective length of L_e feet of conductor moving at the speed of S feet per second in a field of density $\mathfrak{B}$, therefore the E.M.F. generated is

$$E = \frac{72 \times 10^{-8}}{b} \times L_e \times S \times \mathfrak{B} \quad . \quad . \quad (97)$$

from which follows the field density,

$$\mathfrak{B} = \frac{b \times E \times 10^8}{72 \times L_e \times S} \quad . \quad . \quad . \quad . \quad (98)$$

In equation (98) the length, L_e, of effective armature conductor depends upon the polar embrace, which, in turn, is determined by the ratio of the distance between pole corners to the length of the air-spaces; and can be expressed in terms of the total active length of wire by

$$L_e = L_a \times \beta \quad . \quad . \quad . \quad . \quad . \quad (99)$$

Inserting (99) into (98) we obtain the actual field density:

$$\mathfrak{B} = \frac{b \times E \times 10^8}{72 \times \beta \times L_a \times S} \quad . \quad . \quad . \quad (100)$$

where $\mathfrak{B}$ = actual field density of dynamo, in lines of force per square inch;
b = number of bifurcations of current in armature;
E = total E.M.F. to be generated in armature, in volts;
β = percentage of polar arc (see Chapter 34);
L_a = length of active armature conductor, in feet, formula (3), or (101);
S = conductor speed, in feet per second, formula (5).

Since, in a newly-designed armature, on account of rounding off the number of conductors to a readily divisible number, and the length of the armature to a round dimension, the actual length, L_a, of the armature conductor, in general, is somewhat different from that found by formula (3)—as a rule, a little greater a value is taken; it is preferable to deduce the accurate value of L_a from the data of the finished armature:

$$L_a = K \times \frac{l_a}{12} = \frac{o \times u}{p} \times \frac{l_a}{12} \quad . \quad . \quad (101)$$

where K = total number of conductors on armature;
l_a = length of armature core, in inches;
o = number of wires per layer;
u = „ „ layers of armature wire;
p = „ „ wires stranded in parallel.
} see Chap. 9.

Formula (100) for the actual field density of toothed and perforated armatures can also be used for smooth cores, and may be applied to check the result obtained from (96).

For the application to smooth armatures, however, the polar embrace, β, in formula (100), is to be replaced by the corresponding value of the effective field circumference, β', obtained from the former by means of Table XXXII., Chapter 20.

If it is desired to know the real field area in toothed and perforated armatures, an expression for A_f can be obtained by combining formulæ (93) and (100)—thus:

$$A_f = \frac{\Phi}{\mathfrak{B}} = \frac{72 \times \beta \times L_a \times S \times \Phi}{b \times E \times 10^8} \quad . \quad (102)$$

This formula, which gives the mean effective area actually traversed by the useful lines cutting the armature conductors, is very useful for the investigation of the magnetic field of toothed and perforated armatures.

34. *Percentage of Polar Arc.*—The ratio of polar embrace, to which frequent reference has been had in Section 33, is determined as follows:

(*a*) *Distance Between Pole Corners.*—The mean distance between the pole corners, e_p (Fig. 47), is decided upon according to the rule alluded to in Chapter 33—viz., the rule of making that distance from 1·25 to 8 times the length of the two gap spaces, according to the kind and size of the armature and to the number of poles (see Table XLVII.).

Denoting this ratio of the distance between the pole corners to the length of the gaps by k_{11}, this rule can be expressed by the formula:

$$e_p = k_{11} \times (d_p - d_a) \quad . \quad . \quad . \quad (103)$$

where d_p = diameter of pole-pieces, in inches;
d_a = diameter of armature core, in inches; for toothed and perforated armatures d_a is the diameter at the bottom of the slots.

Digitized by Google

The value for k_{11} for various cases may be chosen within the following limits.

TABLE XLVII.—Ratio of Distance Between Pole Corners to Length of Gap Spaces for Various Kinds and Sizes of Armatures.

Capacity in kilowatts.	Value of ratio, k_{11}.					
	Smooth armature.				Toothed or perforated armature.	
	Bipolar.		Multipolar.			
	Drum.	Ring.	Drum.	Ring.	Bipolar.	Multipolar.
·1	1·5	2·5	1·5	2·5	1·25	1·25
·25	1·75	3	1·75	2·75	1·5	1·3
·5	2	3·5	2	3	1·75	1·4
1	2·25	4	2·25	3 25	2	1·5
2·5	2·5	4·5	2·75	3·5	2·25	1·6
5	3	5	3	3·75	2·5	1·7
10	3·5	5·5	3·25	4	2·75	1·8
25	4	6	3·5	4·25	3	1·9
50	4·5	6·5	3·75	4·5	3 25	2
100	5	7	4	4·75	3·5	2·1
200	5·5	7·5	4·25	5	3·75	2 2
300	6	8	4·5	5·25	4	2·3
400	—	—	4·75	5·5	—	2·4
600	—	—	5	5·75	—	2·5
800	—	—	—	6	—	2 6
1,000	—	—	—	6·5	—	2 7
1,200	—	—	—	7	—	2·8
1,500	—	—	—	7·5	—	2·9
2,000	—	—	—	8	—	3

Whenever k_{11} can be made larger than given in the above table without reducing the percentage of the polar embrace below its practical limit it is advisable to do so, and, in fact, this ratio in some modern machines has values as high as $k_{11} = 12$.

(To be continued.)

CARRIAGE AND HARNESS LIGHTING.

Some time ago we referred to the electric lighting of one of the German Emperor's carriages, and to the fact that for the convenience of the coachman in driving along dark thoroughfares electric lamps were arranged on portions of the harness. It now appears that a German firm (Messrs. Wensky and Steinbrink, of 225, Friedrichstrasse, Berlin) is making a speciality of this particular application of electricity, and that various carriages and harness may be seen electrically lighted in that city. Fig. 1 shows the arrangement of lamps placed at the side of the horse's head; Fig. 2 a lamp fixed on the breast-piece; and Fig. 3 two lamps arranged on the collar. The conductors, which are arranged along the harness, are contained in indiarubber tubes which are sewn into the leather so as to be protected from rain and damage.

The lamps are energised from an accumulator of from four to six cells, arranged in a box weighing from 18 to 25 kilogrammes. The cells are ebonite boxes filled with a gelatinous mass, but no acid fluid is used. The battery, the outside dimensions of which are from 30cm. to 40cm. in length by 18cm. to 20cm. high, is placed under the coachman's box. The arrangement adopted by the German Emperor for his four-in-hand drawing a victoria is shown in Fig. 3.

ELECTROMAGNETIC SYSTEM OF TRACTION.

The New York *Electrical Engineer* of Nov. 28 contains an illustrated description of a system of traction introduced by the Electromagnetic Traction Company, of Corcoran-building, Washington, D.C. It appears that this method is now being worked in daily service upon a branch of the Eckington and Soldiers' Home Railroad, about one mile in length, situated on North Capitol-street, Washington. It is said to fully comply with the three main requirements of an electric railway—viz., minimum first cost of construction, maximum economy in working, both of power and maintenance, and absolute safety to both passengers and general public. The car has suspended from the underside of its truck two iron bars, the same length as the car, hung upon light springs and adjustable by means of screws, known respectively as the energising and collecting bars. Beneath one of the seats of the car is a small storage battery, consisting of six cells, arranged to give a current at a pressure of about eight volts, and connected to the energising bar. In the centre of the track are placed, at intervals of about 15ft., hermetically sealed cast-iron boxes, upon the lids of which are two raised surfaces, known as the energising and collecting plates respectively, corresponding with the bars suspended from the car, which slide lightly upon them. Securely attached to the under-side of the lid of each cast-iron box is a simple electromagnet wound with fine copper wire, one end of which is connected to the energising plate. The free poles of the magnet hang down vertically, and work in connection with an armature attached to a bridge-piece. Upon this are two carbon faces, directly above each of which is a corresponding carbon face fixed to the slate bed of the magnet. One of the fixed carbon faces is directly connected to the main cable, which conveys the 500-volt current from the generators at the power-house. This runs in an iron pipe through all the boxes, and the other carbon face to the collecting plate upon the box lid. The operation of the car then becomes as follows: The battery discharges its low-pressure current along the energising bar through the corresponding plate upon the box lid to the electromagnet, which upon becoming energised instantly attracts the armature and bridge-piece, thus bringing all four carbon faces into close contact and completing the circuit, which allows the current to flow from the main cable up through the collecting plate to its corresponding bar upon the car and thence to the motors. This applies only to single track.

Digitized by Google

Where there is a double track the arrangement is somewhat modified, and in the new roads now under construction upon this system another novel feature has been introduced in the shape of a metallic return, which is effected by simply adding a third or return circuit bar to the car, and connecting a third contact plate with a return cable, laid in the same trench with the main cable. For double track the construction is as follows: The cast-iron boxes, at the same distance apart as in the case of the single track, are placed between the tracks and the electro-magnets, for both tracks are placed in the same box. The collecting, energising, and return contact plates are then set in the centre of the track in the same manner as for single track, with the exception that they are set upon blocks of either terra-cotta or granite, instead of upon the lid of the cast-iron box. All the connections are made in a cast-iron watertight dish underneath the blocks, and taken to the cast-iron box between the tracks in an iron pipe.

INSTITUTION OF ELECTRICAL ENGINEERS, Dec. 13.

The annual general meeting of the above institution was held last night, Mr. Alexander Siemens in the chair, when, after scrutineers had been appointed for the balloting list of the new council and office bearers, and for new applications for membership, the **Secretary** read the annual report, from which it appeared that during the year there had been added 14 foreign members, 13 members, 145 associates, and 123 students, making a total of 295 additions. There had been lost by death four foreign members, one member, three associates, and one student. There had also been a few resignations. The Salomons scholarship had been awarded to Mr. Edward E. Holmby, a student of the Finsbury Technical College. The Institution premium of £10 had been awarded to Mr. H. D. Wilkinson for his paper on "Electric Tramways in the United States and Canada," other papers having been ineligible owing to the authors being members of council. The three-guinea prize for students had been awarded to Mr. J. C. Harris for his paper on "Secondary Batteries," and two others were commended.

It was gratifying to note that the quality of the papers read at the students' meetings had greatly improved. It had been arranged to control the Willans Memorial Fund jointly between the Institution of Electrical Engineers and the Institution of Mechanical Engineers. It would be awarded by the council of the respective institutions once every three years. The first award would be made in December, 1897, and by the Council of the Institution of Electrical Engineers. Contributions had hitherto been made to the expenses of the president's conversazione, and it was now intended that the Institution should defray the whole expense. With respect to the building fund, £3,000 of the general investment fund had been transferred to the building fund, and it was hoped that the latter would increase. The Board of Trade were consulting the Council about various matters, such as light railways. The finances of the society were satisfactory, there being £1,010 in hand on account of the general investment fund. There had been added to the library 56 books, besides periodical literature.

Mr. A. Siemens moved the adoption of the report, which he said showed that considerable progress had been made.

Mr. S. Z. de Ferranti seconded the motion, which was adopted unanimously.

Prof. Hughes moved a vote of thanks to the Institution of Civil Engineers for the loan of the hall, and mentioned that the Institution in question had all along lent them a helping hand, and had assisted them in their methods of procedure. They had been both kind and liberal.

Mr. Raworth seconded the motion, which was carried with applause.

Sir Henry Mance moved a vote of thanks to local honorary secretaries and treasurers, and this having been seconded by **Mr. Aylmer**, was also carried.

Mr. R. E. Crompton moved a vote of thanks to Sir David Salomons for his services as honorary treasurer. His initiative in the matter of the building fund would at no long data put the Institution in possession of a building of their own.

Mr. Shoolbred seconded the motion, which was cordially adopted.

Sir David Salomons, in returning thanks, said he was not a member when the Institution was originally formed, but he joined shortly afterwards, when there were 200 members. On January 1 last there were 2,316 members on the books, and the number now probably was 2,500. They had drawn into their net the greatest men of this land, as well as those of other countries. At one time the surplus of the Institution was £200, which an accountant would put down to furniture in hand, but now the annual surplus was £1,000. He hoped that every year a good sum would be put down to the building fund. It had been said that foreigners were thrifty, and he trusted, in respect to the provident fund which they had started, that members in times of prosperity would contribute to it so as to help their poorer members.

Mr. R. Gray moved a vote of thanks to the honorary auditors, Messrs. Danvers and Stroh, and this was agreed to.

Mr. Mordey proposed the "toast"—correcting himself to "vote of thanks"—to Messrs. Wilson, Bristows, and Carpmael, the honorary solicitors, which, having been agreed to, a member of the firm responded suitably.

The following candidates were then balloted for:

Member.—Thomas Barton, the Electric Works, Blackburn.

Associate.—F. C. Dixon, care of Messrs. Martin and Co., Jackson House, Calcutta.

Students.—Stanley Beeton, "Heathfield," Haverstock-hill, N.W.; Arthur Holroyd Sears, Finsbury Technical College, Finsbury, E.C.; Henry William Kennedy Irvine, Henry Herbert Stanley Marsh, Roland Sydney Robertson, and Richard Norman Vyvyan, Faraday House, Charing Cross-road, W.C.

The discussion was then resumed on the three papers on electric traction which were read at previous meetings this session.

A Member stated that the papers read showed that little improvement was required as respected overhead details on electric lines, but with regard to bonding, there was a deficiency. He drew attention to the rail bond which was described and illustrated in our issue of the 23rd ult., page 600. In the past the railway bond seemed to have been a rather unhealthy item in the history of traction.

Mr. F. B. Lea was pleased at the opportunity which had been given of considering the question of electric rack railways. In the first place, Dr. Preller might have given particulars as to the economy of electricity as compared with steam on such lines. As electricians they were glad to note electrical economies, but it was inadvisable to claim too much. Besides, it was difficult to find two lines which could justly be compared. He would like to know what was the cost for motor repairs on the Barmen line, which was on the step-rack system, for jarring and jolting would have a bad effect, the jolting being caused not by roughness of the road but by the change of load as the teeth engaged and disengaged. Dr. Preller had confined his attention to those rack railways, which were for the same purpose as the famous Duke of York—they first went up a hill and then went down again. The field on the Continent, however, was not so much for independent lines as described, as for systems in mountainous districts where there were levels and ups and downs. When steam was used for such purposes, the locomotives had a double set of cylinders, and such a system was very economical. Electric locomotives could also be made for such combination work. It was to be hoped that great extensions would be made in this country in connection with electric traction now that the light railway question was coming to the fore.

Mr. J. H. McGraw, of New York, stated that he was glad to see what had been done in this country in regard to electric and cable traction. Although considerable work on those lines had been accomplished in the United States, he felt confident that both England and the Continent would soon be abreast of what had been done in the former country, and perhaps in many cases exceed them. Rapid transit was one of the most important industries in America, and he extended a hearty invitation to the members of the institution to visit that country, where every facility would be afforded them in the way of inspection and information.

Major-General Webber hoped that in a year or two some of the members would be able to respond to the invitation given by the last speaker, and that the information suggested would be available to them. Referring to the recent conference held at the Board of Trade, and which the president of the Institution and himself had jointly attended, he mentioned that in Belgium, Denmark, and Spain light railways had been constructed which enabled produce to be brought from the point of production to the places of consumption, and, notably, to the English market. In this connection they ought to go one better in this country. The traffic on such lines, which should act as feeders to the main lines, was not such as would, on the face of it, recoup electrical engineers for erecting a generating station with two or four trains daily. A solution of the problem might, however, be found in traction by storage. If engineers would only turn their attention to the subject, there would be a development of traction by storage.

Prof. Sylvanus Thompson gave a comparison between the electric tramway work in the United States of a few years ago and of the present. Then this class of tramway acted as one or more social factors, and removed the local traffic from the main lines to the benefit of the latter's through traffic, instances of which he cited at Pittsburg and New Jersey. In fact, the Pennsylvania Railway Company had facilitated this diversion with advantageous results to itself. A common gauge should be adopted in this country so that light railway cars could be also operated on main lines.

Mr. W. J. Carruthers-Wain, the president of the Tramways Institute, observed that the failure of storage-battery traction had been due to a variety of causes, some of which he enumerated. After alluding to the success of the overhead system at Walsall, the speaker concluded by referring to forthcoming tests of the Thercy-Oblasser battery on the Birmingham lines.

Mr. S. Z. de Ferranti, after referring to the causes of the backwardness of electric traction in this country, suggested that it was to the interest of the whole of the electrical branches to unitedly promote electric traction.

After some remarks from **Mr. Sharp** concerning varying loads on the line at the generating station, in which he described a flywheel which he thought would tend to greater efficiency, and from **Mr. Darras**, in regard to the gearing of motors, the authors of the three papers on traction replied, this bringing the meeting to a close.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

MUNICIPAL REPAYMENT OF LOANS.

Perhaps the most important question to any municipal body when discussing the question of electric lighting is that relating to the repayment of loans. A conflict of opinion has arisen upon this question, and in this matter the electrical industry has so far not seemed to trouble itself. On the one hand, high authorities say that a loan for electric lighting purposes may well be repaid over a long period of years, while others say not so, and the Treasury, together with the London County Council, have adopted the latter view. An estimate has been framed as to the life of various portions of the apparatus used. Averaging these, the final conclusion of the County Council is to adopt two periods for the repayment of loans obtained to defray the initial cost of electric lighting. Thus the loans for outlay upon land, buildings, culverts, bare copper mains, and patent royalties can be repaid in fifty years, while twenty years is the limit for all other purposes. In hearing or reading such conclusions as these, it is necessary to rub the eyes in order to be certain if the world is awake. Mr. W. H. Preece, in some remarks made at Hampstead to municipal engineers, evidently did not agree with these views. He contended that from the nature of things it was absolutely necessary to keep an electric light plant at the highest pitch of efficiency, and, therefore, the question of depreciation hardly came in. Ten years hence the plant must be as efficient as to-day. Why then depreciate? If there is no necessity for a municipality to depreciate, why restrict the time of payment to so short a period as twenty years. The most temporary of all electric plant is to be found in the meters, and these are expected to last five years. Now, taking that one item alone, we cannot expect the meters to follow the example of the "one-hoss shay," and everyone to last for exactly five years and then tumble to pieces. The actual state of the case—that is, the actual practical state of the meters—at the end of every five years will be that all will be efficient. There may be repairs and even renewals month in and month out, but, on the whole, efficiency will be maintained. Now, what a municipality really has to do if the capital for meters was to be repaid at the end of five years, and the facts are correctly stated that the meter has a life of five years only, will be to maintain efficiency out of revenue, and at the same time repay the initial capital. Suppose meters initially cost one thousand pounds; in five years, according to this estimate, one thousand pounds must be spent upon them to keep them efficient, and at the end of five years they are known to be efficient. This seems very like heavily handicapping the ratepayers unnecessarily. There is no valid reason that we can see why the initial outlay should not even in this case be spread over, say, twenty-five years without averaging with the outlay on hand. Of course, there is another way of treating these accounts. All renewals and all repairs, except the most trifling ones, can be placed to capital account, so that capital account is never closed with the municipality, just as it is never closed with the company. In both

Digitized by Google

cases the capital account would then be unvaried, for new capital would be annually created equivalent to the old capital paid off. The good of this cannot well be seen. Why are many municipalities so chary of undertaking work which would benefit the community, except from the knowledge that the initiators of such movements throw a heavier burden upon their constituents than ought to be so thrown. In almost every case of municipal activity the same argument holds good. If they lay out public parks, the burden of so doing is thrown upon the present and the immediate future ratepayers; but the park won't run away or grow less, or be less beneficial to the community. We incline to the opinion that there is no reason why the repayment of loans for electric lighting purposes should not be spread over a period of fifty years. We would not make it longer, because the future is uncertain. Tallow has given place to gas, gas is to give place to electricity, and it may be—we know not when or how—that electricity will give place to some other form of illuminant. We think, however, that electricity is good for fifty years.

Justice needs that both be heard."

HYSTERESIS.

SIR,—I should esteem it a great favour if you would kindly allow me a corner in your widely-read journal to put a question to which perhaps one of your numerous readers will be good enough to reply.

In Dr. Fleming's "The Alternate-Current Transformer," vol. i., three forms of hysteresis are mentioned—viz., magnetic, static, and viscous.

What I should be glad to know is whether "magnetic" hysteresis and "static" hysteresis are one and the same thing? Dr. Fleming apparently uses both terms to express the "lagging behind" of the magnetisation, and gives the formula $E = -\int I\, d\, H$ for the energy spent per unit volume in performing the cycle. On page 65 he calls it "magnetic" hysteresis, and on page 69 refers to "this static hysteresis."

I find in Prof. S. P. Thompson's "Dynamo-Electric Machinery" no mention whatever is made of "static" hysteresis.—Yours, etc.,

STUDENT.

THE CONTROL OF TRANSFORMING LOSSES ON THE BEDFORD ELECTRIC SUPPLY SYSTEM.

SIR,—In your excellently detailed description of the Bedford electric lighting scheme, just arrived at a successful issue, you describe one detail in which I take considerable and particular interest. I refer to the switching gear for changing over the load at the sub-stations from large to small transformers, or *vice versâ*, as the conditions require. It is satisfactory to see that the engineers of the scheme were bold enough to adopt some such system of controlling the transforming losses, in view of the general neglect of the problem by other designers of electrical supply schemes. But looking at their essay in this particular direction as impartially as I can, I cannot help regarding it as just a pity they adopted the method they did, seeing that there was a better and simpler method available. For with due humility I would submit that my method of controlling transforming losses as set forth in my patent No. 7,266/93, would have better served their purpose, and proved a simpler, cheaper, and generally more reliable means of effecting the desired reduction of the transformer loss at light loads. In support of this I will first describe the way I should have applied my system to the case, and then contrast it with the method actually used.

Generally described, my system consists of the use of a distributing network of three-wire mains fed by sub-stations in which the transforming plant is arranged as follows Two comparatively small transformers feed the two sides of the three-wire system. These are always in action. Another much larger transformer or group is put across the outer conductors of the three-wire mains. This is to take the heavy load, and is the part of the plant that is put out of action during light load. On the primary side the transformers are fed from the generating station thus: the large transformer is connected to a pair of primary mains, and the two smaller transformers are put in series across the same mains. Their junction is also connected to a third main from the station of smaller section than the other two.

At the central station the alternator armature is divided into two equal sections in series when at full load, and the before-mentioned third main would then be connected to the junction of the two sections when in series, the first pair of mains being connected to the terminals of the series. All connections at the sub station end are permanent, through whatever fuses and hand switches may be required.

If the alternator gives 2,000 volts, there will, of course, be 1,000 volts between the third, or neutral, primary main and either of the two first, or outer, mains. The large transformer will convert from 2,000 to, say, 200 volts; the two smaller ones from 1,000 to 100.

With this arrangement and a suitable switch at the central station by which one of the outer primary mains can be thrown over on to the same terminal as its fellow, and at the same time the two sections of the alternator be thrown into parallel connection with each other, and across the third or neutral main terminal and the one carrying the two outer mains, the system is complete.

By making the change over described, or *vice versâ*, the large transformer at the sub-station will be put completely out of action, or the reverse, without breaking circuit either on the primary or secondary sides of the transformers.

No automatic switch whatever is required for this operation, though, of course, if desirable, the central-station switch may be made to operate automatically.

In the particular case of the Bedford sub-station, if the conditions were such as to permit a very accurate balancing of the low-pressure network, I should use in each sub-station, arranged as previously described, one transformer of 24,000 watts capacity and two of 3,000 watts capacity. If it were not possible to guard reasonably against a want of balance sufficient to blow the fuses of or endanger either of the small transformers, I should either make them larger, and reduce the dimension of the large transformer to correspond, or I should use a device as follows:

From the centre point of the secondary of the large transformer I should bring out a connection, and join it through a magnetic cut-out to the neutral main of the low-pressure system. The cut-out when open would be designed to short-circuit the outer mains of the secondary system through a coil, that would operate to close the cut-out when the current flows through it (the coil). By this means, which there is not space to describe in detail here, the centre connection of the large transformer is duly coupled to the neutral main when the transformer is active, and severed when it is out of action. As it is a dead short-circuit that actuates the cut-out both ways, it can hardly fail to act instantly the change over is made at the central station.

The points of contrast between my method and that adopted at Bedford are therefore:

In my system there are no idle mains at any time, and no idle transformers at full load, as there is in the Bedford scheme. Less transformer plant and a smaller extra primary main are therefore required.

In my system there are no automatic switches in the sub-station, and therefore not under supervision, as at Bedford. At the worst there may be a simple double cut-out controlling a single connection which carries a small fraction only of the load.

Digitized by Google

In the Bedford method there is no need for separate armature sections in the alternator, as in mine, but this is a very small matter.

It seems to me that from the financial point of view, as well as from the working aspect, my system has a very decided advantage. T. WHITCHER.

REVIEWS.

The Electroplater's Handbook: A Practical Manual for Amateurs and Young Students in Electro-Metallurgy. Second edition, enlarged. Whittaker and Co. Price 3s.

We like Mr. Bonney's book, and the fact that it has entered a second edition shows that others like it too. Almost all his paragraphs are simple descriptions that cannot fail to be easily understood by the reader. The book is admittedly a compilation, but it is a compilation differing from the ordinary run of such books, in that the author knows something of his subject, which many pure bookmakers do not. Again, the author restricts himself to the consideration of such things as are pretty generally agreed, and when he mentions something not immediately proven by his own experience he gives the name of his authority. This is as it should be. If we might venture to suggest a modification when another edition is called for, it would be to largely curtail Chapter III. All that need be given about dynamos is how they fulfil the requirements for plating work. History and descriptions of various makes of dynamos can be relegated to other books.

LECTURE XIV.—GENERAL DESCRIPTIVE KNOWLEDGE OF MAGNETS AND ELECTROMAGNETS. — BEST METHOD OF WINDING ELECTROMAGNET COILS FOR VARIOUS SERVICES.

(Specially contributed.)

The Earth's Magnetism.—We have seen that a small magnet free to move in a vertical plane takes up a position which is really due to the direction of the earth's lines of force. Let N S, Fig. 1, represent the earth, and F F a line

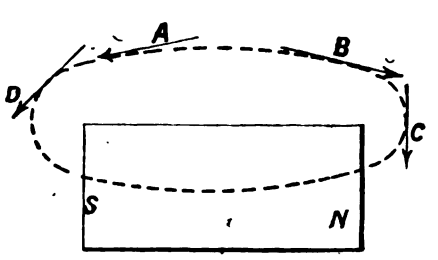

FIG. 1.

of force, and A B C D magnets. These magnets in their different positions place themselves tangential to the line of force, hence in the different positions will point in different directions, according to the curvature of the lines of force. We can easily see, then, that a magnet placed

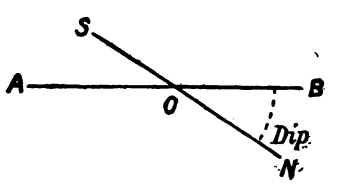

FIG. 2.

anywhere except at the magnetic equator is not parallel to the earth's surface, *nor does either of its poles point directly towards either of the earth's poles*. The angle which the magnetic axis of such a needle makes with the horizontal line at that point is called the *angle of dip*, or of *inclination*. Thus, if A B, Fig. 2, is the horizontal line, and S N the direction of the magnetic axis of the magnet at the point O, then N O B is the angle of inclination or of dip.

The earth's lines of force are not symmetrical around it, hence the angle of dip varies somewhat in the same latitudes. The material construction of the earth's crust at any particular place influences the lines of force. Again, and for the same reason, the earth's magnetic equator is an irregular line, and not exactly midway between the poles. I have said that the earth's magnetic poles are not coincident with the geographical poles; therefore the lines of force are not parallel with the geographical meridian of longitude. We have seen that when a magnet is free to move vertically it has an angle of dip; when free to move horizontally, as in this case of the compass needle, its axis comes to rest in a direction pointing in the direction of the magnetic north and south poles. If A B, Fig. 3,

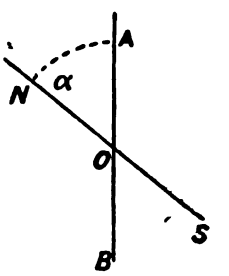

FIG. 3.

represent the geographical meridian at any place, O, and C D the magnetic meridian at that place, the angle A O D is called the angle of declination. Once more, the

Angle of inclination or angle of dip at any place is the angle between the direction of the magnetic axis of a magnet free to move vertically and the horizontal line at that place.

Angle of declination is the angle between the geographical meridian and the magnetic meridian at any place.

The magnetic equator is an irregular line around the earth when a magnet has no angle of dip.

The earth's magnetic poles are not fixed. Thus the north pole fluctuates from one side of the geographical north pole to the other. At the present time it is now about 18deg. or 19deg. W.

The magnetic meridian is the vertical plane in which the axis of the magnet comes to rest, and the two horizontal directions in this plane are respectively the magnetic north and south.

The value of this property of a small magnet placing itself in the magnetic meridian pointing in the direction of the north and south magnetic poles is of incalculable value to sailors. Such a magnet, either single or in a group of magnets like Lord Kelvin's, forms the mariner's compass, by means of which the sailor finds his way across oceans, where there can be no watermark to guide his course.

Winding Electromagnets.—I shall not endeavour to describe the various types of electromagnets, because till within the last few years the makers of electromagnets proceeded by rule of thumb more than upon any principles of the subject. The advanced student in this direction must of necessity consult Prof. Silvanus P. Thompson's large book, in which he will find the history, the principles governing the design of electromagnets, and the design, set forth at considerable length in an admirable manner. The two great purposes for which electromagnets are used to which I shall refer are (1) the attraction of an armature, and (2) to generate a current of electricity. Now, for either of these purposes we require a dense field at the point of action, and not only do we want a dense field, but we want that field in a medium, such as air, through which the armature to be pulled or the wire to be moved can pass. Compared with iron, air has great resistance to the passage of lines of force, and, therefore, for economy's sake we

Digitized by Google

want as little air space in our magnetic circuit as possible. We have to consider:

1. How to get our lines of force (magneto-motive force).
2. The media through which the lines pass (resistance).
3. The number of lines.

The lines of force are obtained by means of a current through a conductor. The field around any given length of conductor—say, an inch or foot—carrying a constant current—is constant, provided the medium through which the lines go is constant. Assume the field to consist of so many lines of force in a given area. If I double the current in the conductor the number of lines is doubled, other things remaining the same; or if I halve the current, the number of lines of force is halved. The number, then, is directly proportional to the current, resistance remaining the same.

Further, if I halve the resistance of the magnetic circuit the number of lines is doubled with current constant, so that the number is inversely proportional to the resistance.

Ampere-Turns.—All this is similar to the conductive circuit, which we have already investigated. There we had a unit of pressure, or E.M.F.—the volt—and here we will take as our unit a conductor carrying an ampere of current and making one complete turn or circle, or a ring conductor carrying an ampere of current. To this unit the name **ampere-turn** has been given. Of course, you quite understand that the same effect is obtained whether you use an ampere-turn or 10 turns each carrying one-tenth of an ampere.

Magnetic Saturation.—There is one point to which your attention must be given. It is that no media has yet been discovered through which you can pass an unlimited number of lines of force; that means, simply, the density of field is limited. An ampere-turn gives us a certain number of lines in a given circuit; the addition of another ampere-turn, as I have said, will double the lines in this particular circuit. And so you can go on, up to a point, adding ampere-turns and getting a corresponding increase of lines; but when this point is reached, you do not by adding ampere-turns get a corresponding addition of lines. When the point is reached and the resistance medium no longer admits the generation of lines of force—or only to a very limited extent—we say the medium is saturated. Thus with good wrought iron we get saturation when about 125,000 lines to the square inch pass through; with cast iron, 70,000 lines per square inch is about the limit of saturation.

This shows it is no good adding ampere-turns after the field is saturated. Up to the point of saturation there are two ways of increasing the density of field:

1. By adding ampere-turns.
2. By decreasing the sectional area of the field.

Suppose a pull is required upon an armature, and a uniform field of six square inches is used, with ampere-turns to give a total of 125,000 lines. We have just seen that this number of lines is the limit for a square inch of good wrought iron. But if the whole magnetic circuit is of such iron, then by decreasing the section from six square inches to one square inch, we should increase the resistance of the circuit six times, and thus require six times the ampere-turns to get the required magneto-motive force. Therefore, the question of weight, cost of materials, and cost of construction play an important part in the design of electromagnets. As Prof. S. P. Thompson says, "We now see how in designing electromagnets the length of the iron core is really determined: it must be long enough to allow of the winding upon it of the wire which, without overheating, will carry the ampere-turns of exciting current which will suffice to force the requisite number of magnetic lines" across the resistances in the useful path.

Transmission of Power in Germany.—At Pforzheim, where a central electricity station was started a short time ago, a strong demand has sprung up for current for power purposes, on account of the cheapness of this method. Applications have been received for 500 motors for working polishing brushes in *bijouterie* works.

ON THE COMMERCIAL POSSIBILITIES OF ACCUMULATORS FOR TRAMCAR TRACTION, CONSIDERED AS A MUNICIPAL UNDERTAKING.*

BY ALFRED H. GIBBINGS, MEMBER.

Introductory Remarks.

During the past 12 months I have had occasion to consider the question of electric traction in each of the many forms in which it is placed before the public in general, and municipalities in particular, by the interested advocates of the respective systems. The fact is, the Corporation of Hull had it in contemplation to apply for an Act of Parliament empowering them to acquire and work the tramway system of their own borough. I was, therefore, requested by my committee to place before them a report as to what had already been done in this country in the direction of electric traction, so that at least as far as this form of traction was concerned they would be in a position to consider each of the different methods on its own merits. In my final report to the committee I submitted that, in my judgment, accumulators would offer greater advantages to the town than either of the other forms. The technical journals, however, in which this recommendation was published did not, I am sorry to say, include the whole of my report to the Corporation. The consequence was (as might, indeed, have been anticipated) that several criticisms were passed questioning the commercial and financial results of the method I recommended, whereas, in fact, these results were the determining factors in the conclusion to which I ultimately arrived.

When the subject of electric traction is seriously approached by electrical engineers, corporations, and companies, the usual course of procedure and investigation is to consider the relative intrinsic merits of the different systems, apart from the very important question of the conditions under which the method is to be employed. Each of the three forms of electric traction—namely, the underground channel or conduit system, overhead wires or trolley system, and accumulators—has its own very able exponents in the technical Press and elsewhere, but, unfortunately, the majority of the writers are themselves interested in the system which they advocate, and for this reason such papers cannot be considered to have the same value as if the authors had been entirely disinterested experts. I am safe, perhaps, in admitting that the overhead wire or trolley system has proved a greater practical and financial success than either of the others. This statement, however, refers to cases in which a special plant has been put down to generate energy for the specific purpose of working whichever system has been adopted, and as far as my knowledge extends every comparison between the three systems in regard

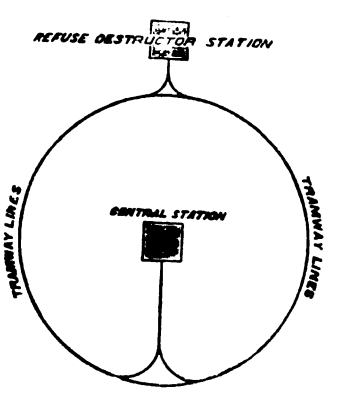
* Paper read before the Northern Society of Electrical Engineers, December 10, 1894.

Digitized by Google

to cost and working efficiency has been made under these special circumstances. I am, however, digressing a little, and will now resume. The recommendation to adopt accumulators which I ultimately submitted to the Corporation of Hull was based upon an entirely new departure, in the working out of which I have been very interested. My object in bring the subject before your notice in this paper is that my reasons and conclusions may be fully discussed, in the hope that a new light may be thrown upon municipal undertakings. I have come to the conclusion that the secret of success lies not so much in the adoption of any particular method of electric traction, however superior, as it does in enlisting and utilising services which other enterprises can be made to contribute. Separately, they may be only just paying their way, but combined, it will probably become possible to make an exceptional success of both. Let me clear the way, in the first place, by removing any misconceptions there may be that the circumstances and conditions of the town of Hull relative to electric traction are unique in their nature. Such is not the case. There are, indeed, dead level roads, and these certainly offer many advantages to accumulator traction which might not apply elsewhere. On the other hand, there are many dock bridges which open and close, and these present a mechanical difficulty which, however, can be surmounted without stopping the running of the cars, as it is very seldom that two of the docks' gates are open at the same time. But in point of fact, these special features do not affect the general question we are considering.

The basis on which I now propose to consider the subject of my paper has for its essential feature the possibilities in economical management and working which are within the power of municipal corporations. Municipal corporations are, in this respect, widely different from private or public companies, inasmuch as they are responsible, not for one business alone, but for many and varied undertakings. A public company restricted to the narrow limits of its single enterprise will, of course, select a system which is likely to show the lowest working costs, and such a selection will be to the best interests of the shareholders. But municipal corporations should have wider views. They have many businesses to conduct in the interests of the ratepayers. The system therefore to be selected by a municipal corporation is that which has the greatest tendency to enhance the value and increase the profits of other departments of the corporation. The cost of working, considered from this point of view, though, perhaps, actually heavy and large, may be relatively small.

I will now proceed to a short general analysis of the combination of refuse destruction, electric tramway service, and electric lighting on the low-tension system. For the purposes of illustrating the general arrangement I beg to draw your attention to the accompanying diagram. The large circle of lines represents the tramcar route, with the destructor station on the confines of the town, and the electric lighting station in the centre.



It is now a generally admitted fact that, given modern improvements for the generation of steam, some power can be obtained from refuse destruction. The publication of Mr. Charles Jones's book on refuse destructors has thrown light upon a subject which has hitherto been neglected by engineers, while the popular articles by Mr. Thomas Thomlinson have brought new possibilities before the electrical engineer. To sum up the whole of the evidence contained in Mr. Jones's work, I find that out of 50 destructors at work, destroying from 3½ tons to 10 tons per cell, the power obtained varies from 5 h.p. to 7 h.p. per cell. This power has been generated under conditions for raising steam which have had to be, and will always have to be, modified and made compatible with the complete destruction of the refuse from a sanitary point of view. The question therefore arises, What is the best use to which this power may be put? Hitherto it has found its solution for the most part in the working of mortar-mills and stone-breakers, or as a subsidiary power to an electric lighting station, possibly producing sufficient power for day-load purposes. These applications, however, while their advantages are not denied, do not use one half of the available power for the simple reason that most destructors are in operation the whole of the 24 hours and the hot gases are at night perforce turned into a by-pass flue, and so far wasted. Under every scheme which is at present being tried there is as much power lost as utilised, but in the scheme to which I wish to draw your attention this evening the whole available power is laid under contribution day and night without intermission as far, of course, as the usual engineering considerations will allow.

Now, this is a very important point, upon which I wish to lay particular stress. The difference, therefore, between my proposition and the use to which the power has already been applied, or, in other words, between my scheme and the schemes for utilising the power for the day load of electric lighting stations, may be stated as the difference between horse-power and horse-power hours. The available horse-power with a variable demand is practically an unknown quantity, whereas the utilisation of the available horse-power continuously over a stated and prearranged number of hours is a definite quantity, and one upon which calculations can be made. The suggested probable economy in the first case is a very doubtful matter, but under definite conditions the problem is resolved into calculating the usual losses which always occur through the transmission and transformation of power. Where the power is utilised as an auxiliary to electric lighting one other very serious drawback occurs, which I just briefly point out in passing. I refer to the "standing by" of the main boilers and their consequent daily cooling during the time that the destructor boilers are supplying steam. The period of the earning capacity of the former is thereby rendered very short, and the increased economy of working by the combination is practically neutralised by being swallowed up in interest on the capital outlay. In addition, the boilers are deteriorated by being alternately cold and hot.

Application of the Power.—In a paper of this description it is quite unnecessary to deal in a detailed manner with all the applications to which it is possible to put the power derived from the destruction of refuse. The effectiveness of this power depends largely on the quantity and nature of the refuse to be destroyed, and this, again, varies enormously in different towns. But I have already pointed out that, according to the best authorities and our own knowledge of the relative value of fuels as heat-producing agents, it must be admitted that a refuse destructor cannot be depended upon without the extraneous aid of other fuel to provide its maximum power at any given time. I must not be understood to say that an advisable and economical arrangement might not be devised where coal, for instance, might be used as an auxiliary fuel; but taking the refuse destructor on its own capabilities alone, we may safely assume that as a power producer it is limited to this extent—namely, that it yields a mean steady power only; or, in other words, that it cannot be depended upon for sudden emergencies. We must take it for granted, at the outset, I think, that in every case the refuse destructor may be depended upon to provide a certain minimum power. This minimum power must be adequate to meet the demand made upon it, or, in other words, the plant to which it is proposed to apply the power must be so designed and arranged that at no time shall a sudden and unexpected demand be made upon the destructor which it is incapable of meeting.

In the town of Hull, about 250 tons of miscellaneous refuse are destroyed weekly. This is a small quantity compared with that of other provincial towns. A large portion is composed of dry shop refuse, such as paper, straw, wood, and ashes, while it is not an infrequent occurrence to have to destroy whole ship cargoes of condemned fruits, vegetables, and fish. From observations taken I am well within the mark in estimating that with the necessary alterations to the present destructor we could obtain a continuous power of 45 i.h.p. This 45 i.h.p. would give at least 40·5 e.h.p at an efficiency of electrical machinery of only 90 per cent., or a continuous output of 400 amperes at 75 volts, for it must be borne in mind that under the scheme I am unfolding, the electrical machinery would be designed to always work at full load. This arrangement would be amply sufficient to charge batteries of 25 cells, always keeping a certain number of batteries in parallel according to the rate of charge. Of course, the number of batteries and their size would depend upon the size of car to be propelled, and I have already pointed out that the power at the destructor station can be supplied continuously for the 24 hours. This would be equivalent to doubling the capacity of the plant, as the batteries charged during the night would meet the requirements of the tramcars for half the succeeding day. This power would charge a sufficient number of accumulators to run from about one-half to three-quarters of the trams according to whether the service consisted of 12 or more trams in the hour on the different routes. The remaining portion could be conveniently and economically provided for by supplying another charging station with power from the machines at the central electric lighting station, which machines would be available for this purpose during the day or night, excepting only at the time of maximum demand.

Digitized by Google

In considering the whole matter I had brought before my notice what had already been done with regard to thermal storage. There may be possibilities in thermal storage which are not yet matters of common knowledge. This, of course, may be especially the case where sudden demands for abnormal power for short periods would be made, as in that case the steady and continuous power generated might be stored. But the only reliable working statistics we have are those connected with a steam tramway in India, where the engines obtain sufficient power for one journey from a reservoir of high-pressure steam. It can easily be seen, however, that the hot climate of that country must conduce very largely to the success of the system, as radiation must be at a much less rate than would be the case in England. Indeed, an English winter might render such a system quite inoperative.

Reverting to the two other alternatives—namely, the overhead cable or trolley system and the underground conduit system, the advantages of which mainly consist in economy of working (plant for plant)—I may mention a few of the disadvantages (and consequent expense) attendant upon these systems which do not occur with the use of accumulators: (1) irregular demands upon the generating plant; (2) greater wear and tear of the machinery; (3) capacity of generating plant must be equal to all possible demand upon it: (4) plant standing idle when cars are not running; (5) stringent requirements of the Board of Trade as to insulation and periodical tests; (6) greater original outlay of capital; (7) impossible to economically use the power which the electric lighting station might contribute during the day; (8) inability of the refuse destructor station to supply the whole of the power required; hence (9) necessity to erect independent central generating station to supply additional power required; (10) for reasons contained in (8) and (9), very little, if any, advantage in point of economical working would arise from the aid of the refuse destructor.

The foregoing list of disadvantages is serious enough, but over and above all these I may point out that the power from a refuse destructor when applied to an overhead or underground system would only complicate what is merely a simple scheme. In fact, it would be more economical to put down one complete generating plant for the tramcars appropriating the destructor power to some other purpose, where, as I have already mentioned, the whole power obtainable, as calculated in horse-power hours, would be turned to more remunerative account. The most serious item to be considered is, after all, that of capital expenditure. A heavy original outlay runs away with so much of the profit in the case of municipalities in providing interest and sinking fund. Now, the capital expenditure, be it observed, for the complete equipment of accumulator cars is usually from 50 per cent. to 75 per cent. only of that required for the overhead cable system, according to the track mileage. If the accumulator system can be arranged and worked so that the entire depreciation of the accumulators can be written off per annum out of lower working costs than are possible with either of the other systems, then it is clear that traction by accumulators would be the most highly remunerative system of any form of traction yet devised.

The Advantages of Accumulators.—I have already pointed out that one of the greatest advantages of accumulators for electric traction purposes lies in the fact that the power of a refuse destructor may be utilised to the full, and that in consequence the cost of generating the power (both with regard to fuel and labour) would be extremely small. But if the scheme ended here the advantages would perhaps scarcely justify the especial prominence I have given to it. It is only as the destructor is brought into combination with the central station electric lighting plant that the matter becomes supremely worthy of consideration. I am of opinion, in the first place, that no town has sufficient refuse to supply of itself the whole power required to run its tramcar service, whether by accumulators or other system. Even supposing that sufficient power could be so obtained, it would necessitate an additional capital outlay on buildings, machinery, etc., so great that it would practically be the same as for an electrical station independently worked. But where merely horse-power is available the necessary plant could readily be accommodated. The chief function and value in that case would consist in its being a "relief" station, which would obviate the running of all cars to one point only for recharging purposes. If there were more than one refuse destructor in a town, each of course could be used to form a relief station according to the number and frequency of the cars. I have so far endeavoured to point out the advantages and uses of accumulators in connection with the utilisation of the power derivable from refuse destruction. I now proceed to consider a far more important matter—namely, the advantages arising from charging accumulators for electric traction by means of the available and otherwise idle plant at a low-tension electric lighting central station. These advantages are based upon the following fact: the cell charging can be stopped at the hour when the heavy lighting load comes on, and the full capacity of the plant can then be used for lighting purposes. This at the first glance may perhaps appear a very small advantage, but its full significance consists in the fact that it provides a day load for the central electric lighting station. I have no need to here describe the *modus operandi*; suffice it to say that low-tension central stations are designed for charging accumulators, and by means of independent connections those machines not running in the day or night time could be employed in charging separate accumulators for the tramcar service. As the electric lighting load came on so the different machines would be transferred from the tramcar plant to the main switchboard and *vice versâ*. The question now is, What does this arrangement actually mean both to the tramcar and the electric lighting enterprises? The tramcar enterprise would benefit in many ways—viz.: (1) less capital would be required, not having to provide independent dynamos and engines; (2) there would be, of course, correspondingly less interest and sinking fund liabilities; (3) such expenditure as would fall under depreciation of plant, repairs, rents, rates and taxes, wages of boiler and engine attendants, etc., would be equitably divided between the electric lighting and the tramcar concerns; (4) the management of the tramcars whilst under the supervision of an official and staff would also be controlled by a separate committee which would act conjointly with the electric lighting committee. It must be quite clear, therefore, that co-operation must very largely reduce the working costs of a tramcar system. The cost per unit, whether we calculate per horse-power hour, per car mile, or on any other basis, must be greater where the whole cost of management and working has to be borne by the tramcar service alone than will be the case where by using the resources of the electric lighting plant handsome profits are made in what I may term "spare time." To what extent this co-operation might be developed it is difficult to say, but the fact that each enterprise would save considerable expense to the other is perfectly obvious.

With regard to the electric lighting concern, the acquisition of a substantial day load is of the utmost possible consequence. For the purposes of this paper it will be better to assume that this department merely charges (as an electric lighting enterprise pure and simple) for the current which it can generate and sell. That is, I do not wish to complicate what I have to say by assuming any arrangement between the electric lighting and tramcar committees with regard to sharing the proportions of the costs under the various items common to both enterprises. It will be sufficient if we assume that: (1) the electric light committee retain their independent position and make a definite charge per unit for all current supplied; (2) that this output is merely considered as a day load.

The endeavour to solve the prob of a day load for the central station has resulted in the suggestion of many different methods, but most of these methods at the best would only make use of a very small proportion of the available power. In common with other central-station engineers I have had the problem before me, and a few months ago I endeavoured to show in a contribution to the *Electrical Review* how far the various methods of charging the public for electricity from a central station tended in the direction of encouraging a day load. In the course of my analysis in that article, under the heading of "The Works Cost," I dealt with the available horse-power of a central station, and I cannot do better than read the paragraph: "Let us assume that the available horse-power of a station is 1,000. Multiplying this by the total number of hours (8,760) in the year, gives 8,760,000 horse-power hours. Assuming, on the other hand, that the full capacity of the plant is used on the average three hours only per day, then the total number of actual horse-power hours = 1,095,000, or one-eighth of the absolute capacity. As an assumption this errs, if anything, on the same side, as very few central stations, in fact, are yet reaching the one-eighth of their full capacity in the year. We must now consider this unused available horse-power side by side with those items of cost which would not practically be increased in the sum by generating seven-eighths available output. The items are as follows: (1) wages, except outdoor staff; (2) salaries; (3) repairs and maintenance; (4) rents, rates, and taxes; (5) sinking fund; (6) interest on capital. It will readily be admitted that these are the expenses which really affect the cost per unit delivered to consumer. Yet these remain, to all intents and purposes, constant; practically neither more or less, even when the plant is being utilised to the full. The result, of course, is that where the output is increased eightfold, the rate of cost per unit delivered, so far as these items are concerned, will be reduced to one-eighth."

The remarks I have now quoted with regard to the methods of charging for current are equally true in reference to the arrangement which we are now considering. As an example, I will give actual figures from the working of the electric lighting station at Hull. These may be absolutely depended upon, as we weigh all coal, all ashes, and measure everything consumed. The units generated and delivered are checked in four ways: (1) by Aron meters in the circuit from the dynamo to the switchboard; (2) by the working out of daily load curves taken from readings on the ammeters; (3) by Edmondson meter in the main omnibus bars between the switchboard and the several feeders; (4) by quarterly comparison of the consumers' meter readings. All these we find agree within

Digitized by Google

small percentage. Our lightest weekly output during this summer cost us ·97d. per unit delivered (not generated), including coal at 14s. per ton, and oil, water, waste, and all stores. Our heaviest weekly output during this winter has cost us ·60d. per unit for the same items. Now, with regard to the standing charges just referred to, if we multiply the heaviest weekly output by 52, or, in other words, if we assume the maximum weekly output as the average weekly output, I find that the proportionate cost of the standing charges comes to 1·84d. per unit. Adding both these costs together—that is, the generating cost and the standing charges cost—we get: generating cost, ·60d.; standing charges cost, 1·84d.; total, 2·44d. as the representative total cost per unit for one week, and I have no need to add that I only wish the figures were true for every week in the year. The maximum electrical power used during this model week was 450 for an average of three hours per day, or 9,450 electrical horse-power hours out of a possible 75,600. Now a minimum number of small cars—say, 30, averaging 10 e.h.p. each—would give (neglecting charging losses) 300 e.h.p., which for 90 hours in the week is equivalent to 27,000 electrical horse-power hours, or an increased output of at least three times the usual quantity. As the power required by the tramcars would not vary with the season of the year, but would remain fairly constant, it is possible that this supply would form by far the largest factor of the output for some years. You will at once see my object in giving you these figures. The generating cost, of course, will remain the same—viz., ·60d.—but the standing charges cost will be reduced to one-third, and the gross cost per unit becomes 1·21d. only for all current generated. This figure gives us a very high efficiency; in fact, the very highest efficiency which has ever been obtained from any electric lighting central station in the United Kingdom, or, I venture to say, anywhere in the world. This demonstrates clearly what the co-operation of accumulator cars will do for an electric lighting station, and it may be definitely stated that the combination guarantees a better load factor for every week throughout the year than is obtained by the highest weekly output of the electric lighting alone. It would mean that an enormous profit would accrue to the electric lighting business itself if only 3d. per unit were charged, and the first possibility which is immediately suggested is that of the great reduction which might be effected in the usual price per unit for current. But we must not forget that this possibility is essentially due to the creation of a magnificent day and night load. I am of opinion, therefore, that the standing charges rate should not be divided equally between the tramcar and the electric lighting concerns, but in the inverse ratio of their demand in units throughout the year. In thus charging the users of the electric light with the larger proportion of the standing costs, it would be possible to confer a still greater benefit on the traction enterprise by bringing the whole of its charges to within a 1d. per unit. This price, which includes interest and sinking fund, capital, wages, and power, as far as the generating machinery is concerned, will be found to be a much lower figure than has ever been obtained with any system.

The foregoing arrangement does not necessitate that the traction accumulator cells should be charged at the electric lighting central station. The nearer the charging depôt is to the central station so much the better, in order to avoid loss in transmission and outlay in cables, but it is not an indispensable condition. A special set of cables could readily be laid to any convenient spot. The system of low-tension supply will generally allow and admit of additional cables being easily laid to any point within the area of distribution. You will have observed that the arrangement therein suggested is essentially based upon those facts of which we as engineers are certain. I have endeavoured to entirely eliminate dubious or insufficiently tested possibilities, such as thermal storage, and I have avoided the unnecessary procedure of basing my proof upon comparisons of the working cost per car mile of the different systems, as such figures are generally misleading, and in most cases do not form any proof at all. Admitting and including the heavy depreciation of the accumulator plates, it has been my object to show how accumulator traction can be worked cheaper and more satisfactorily than the other two systems. Hence my ideas are placed before you rather in the abstract than in the concrete. With reference to my figures representing the power obtainable from our refuse destructor, or, for that matter, from any other refuse destructor, providing the requisite quantity of refuse is present, I merely wish to point out that Mr. Jones, of Ealing, estimates for the same number of cells, destroying the same quantity of refuse as at Hull, a continuous power of 50 i.h.p., while I have placed my figures at 45 i.h.p. The refuse at Hull is, in fact, of a drier and more combustible nature than that at Ealing, so that my estimate may be taken as well within the mark. I have had the advantage of seeing the Ealing destructor works, and my assertions therefore may be taken with every degree of assurance.

I have now endeavoured to point out or indicate in this paper a few features in connection with municipal enterprise, which are well worth consideration. I do not for a moment say that the particular instance I have given, and which I have found would be so particularly to our advantage at Hull, is one which in all respects would be found equally advantageous in other towns. But it is the co-operation of departments under municipal control which might be arranged without in any way interfering with the carrying out of the regular or specific work which each department has been created to perform. The tendency, of course, is already in this direction, and many towns are attempting to make some use out of the destruction of their refuse. But there is no reason why such combinations should not be more extensively made, and to this end I have endeavoured to show accumulators, as applied to electric traction, can at the present time be turned to remunerative account.

NEW ELECTRICAL ENGINEERING WORKS.

THOMAS PARKER, LIMITED.

Invitations were issued on Monday by Messrs. Thomas Parker, Limited, of Wolverhampton, for an inspection of their new works, which have just been completed in that town for the manufacture of electrical plant. The works, which were formally opened on Monday by the Mayoress (Mrs. C. T. Mander), have been erected in Wednesfield-road, opposite the goods department of the Midland Railway, and a short distance from the stations of the Great Western and London and North-Western Railway Companies.

The buildings occupy a large site, and are arranged in the most convenient manner possible, whilst the closest attention has been paid to the health of the workpeople. There are erecting, fitting, pattern, and machine shops, and a foundry for brass and iron work. The building at the left of the entrance has been set apart for the erecting, fitting, and machine departments. It has four bays—two of which have a span each of 32ft., and two with a span each of 42ft. 6in., and each of the four measures 150ft. in length—and in connection with each one there are arrangements for travelling cranes. In the first bay there are the main engines for driving the whole of the works, and for testing the machinery before it is sent out. The steam for the engines is supplied by two Babcock and Wilcox boilers. In the second bay there are the larger tools, general erecting and testing machinery. The third bay is used as a machine shop, with lathes, milling machines, drilling machines, and general tools for carrying out work of any size. The fourth bay is for light brasswork, winding armatures, etc. The floor of this large building is of concrete with wood blocks. There is also a railway track, so that it can be connected with the Midland Company's sidings. The machinery is fitted with the latest improvements and every arrangement to secure accuracy and rapidity in working. There are several milling machines, which are now taking the place of the planing machines. Four other large and valuable machines have yet to be laid down. The building is heated with steam from the main boilers by means of radiators. The travelling cranes and machinery are driven by electric motors supplied with current from a dynamo, which will also supply the electric light for the building. The building which will be used for the foundry is 120ft. by 40ft., and will be fitted with a 10-ton electrically-fitted travelling crane. The cupola is a large one placed in a convenient position and has a covered stage, with a hoist for taking up pig iron, coke, etc. The pattern-shop is 80ft. by 40ft., the floor of which is of concrete, over which wood blocks are laid, and heated by steam radiators. Mr. A. P. Brevitt, of Wolverhampton, was the architect, and Mr. Henry Lovatt the builder.

The ceremony of setting the machinery in motion was performed at noon in the presence of a large and representative gathering. Amongst those present were the Mayor (Alderman C. T. Mander), Mr. T. Parker, Mr. T. Graham, Mr. W. Thomas (directors), Mr. T. Bantock, Mr. A. P. Brevitt (architect), Mr. H. Lovatt (builder), Mr. H. G. Powell, Mr. Wilkie (secretary), and Messrs. J. E. Underhill, J. W. Sankey, J. H. Woodward, E. S. G. Rees, C. H. Iles, W. Armistead (the last four named gentlemen being members of the staff). After an inspection of the machinery by most of those present, Mr. Parker called upon the Mayoress to set the machinery in motion, which she did amid cheering from spectators and workpeople. Mr. Parker afterwards presented the Mayoress with a blotter, made from deer-skin leather, of a very delicate-brown colour.

The company having adjourned to the pattern-shop, Mr. T. BANTOCK said that was a very important occasion for Wolverhampton. A successful work of the magnitude and character as that which they saw before them was most important both for those who put their capital into it as well as for the workpeople. He had the greatest pleasure in proposing success to the new undertaking. The health of the new firm was then drunk with enthusiasm.

The MAYOR, as chairman of the company, responded, and

Digitized by Google

said he was pleased to see Mr. Bantock present, and to hear him so kindly propose success to the new undertaking. He (the Mayor) fully believed it was going to be a grand success. They had a very able staff, and a most able managing director in Mr. Parker, whose name in the electrical world was a household word. He could assure the public that the concern was honest from start to finish. There had been no promotion money, the concern had not been "watered," and they had the best chance of success. On behalf of the directors he thanked them for the hearty way in which they had drunk success to the undertaking.

Mr. THOMAS PARKER said he was glad to see Mr. Bantock present, and to know that the Mayor was by his side, upon whom he looked as a tower of strength in connection with that undertaking. The site upon which those buildings had been erected was a field in July last. The idea of starting those works was fixed upon by the gentlemen who formed his staff, who about nine years ago came to Wolverhampton as pupils to him (Mr. Parker) at the works of Elwell-Parker, Limited, and had grown with and taken a large part in carrying out the works that made the name of Elwell-Parker known throughout the world. They had been his staff through the term of his agreement and of service with the Electric Construction Company as their engineer and works manager. They made the term of further union to be the initiation of a new concern. They now gave Thomas Parker, Limited, their united services and experience, and had each subscribed largely to its capital. He wished them to receive from the friends of the firm credit for this. The company were now able to take in hand the largest work which was likely to be required. They intended to do the highest class of work at the lowest cost. They had the newest and best machinery, carefully chosen from seven of the best makers, and bought at the lowest possible price. They had plenty of orders in hand. He had the greatest faith in the future of electrical engineering, where the object was sound and legitimate business. This, he was sure, was the one object of the directors. They had been working upon designs and patterns the last five months, and hoped to be able to offer to the public a better class than they had bought hitherto, and improved designs. They had obtained some important patent rights, and he thought the works would be a standing monument to their chairman, the Mayor, during his mayoralty.

Mr. GRAHAM proposed hearty thanks to Mr. A. P. Brevitt, the architect, and Mr. Henry Lovatt, the builder, for the excellent way in which they had carried out their work. Several electrical engineers had seen the works, and they had candidly declared them to be the best of the kind in the United Kingdom.

Mr. BREVITT responded, and the proceedings were brought to a close.

LIGHT RAILWAYS.

On the invitation of the Board of Trade, a conference on the desirability of making light railways for the carriage of produce from the rural districts was held at 8, Richmond-terrace on Thursday last week. Among the bodies represented were the London County Council, the Association of Chambers of Commerce, the Central and Associated Chambers of Agriculture, and the London Chamber of Commerce. The officials present were: Mr. Bryce, President of the Board of Trade; Mr. Gardner, President of the Board of Agriculture; Mr. Shaw Lefevre, President of the Local Government Board; Mr. Burt, M.P., parliamentary secretary of the Board of Trade; Sir Courtenay Boyle, permanent secretary of the Board of Trade; Mr. F. J. S. Hopwood, assistant secretary of the Railway Department; Mr. Garham Roper, private secretary to the President of the Board of Trade; Major Cardew, electrical department; and General Hutchinson, Major Marindin, Major Yorke, and Major Addison, railway and tramway inspectors of the Board of Trade.

Mr. BRYCE, who presided, said he had called the various bodies together to discuss the desirableness of constructing light railways in rural districts and in places where there was no railway connection at the present time. There had been a great depression in agriculture for some time past. When they turned their attention to several foreign countries, notably Belgium and France, they would see the great development which had taken place in the formation of cheap light railways. The question was whether such lines could be made to give satisfaction to those who might construct them. Considering that 50 years had elapsed since most of our great trunk railways had been completed, comparatively little had been done to facilitate locomotion in the less populated districts for the conveyance of produce therefrom. All that the Board of Trade could do, in many respects, was to keep just ahead of public opinion. They were restricted in their policy by statute, and also by usage, which was scarcely less strong. They could not go far in advance, therefore, of public opinion in very many of the matters that were brought before them. They had always to consider the question of safety and of speed. Another side of the question was whether light railways would relieve the congestion of the passenger traffic in urban districts by providing better transportation for workmen going to and coming from their work, and enable many of those large industries now being carried on in cities to be transferred to rural districts. The formation of light railways would, of course, turn on the question of money, and it would be well if some means could be devised to lessen the cost. He believed the cost of constructing a railway, taking into consideration the land and the heavy parliamentary expense, was little less on an average than £10,000 a mile, but there was reason to believe that a light railway would be formed for something like £4,000 and upwards per mile. If light railways were to be formed, many of the local authorities would have to change their attitude, or they could not have the benefit of these lines. An expensive thing would be the cost of the land. The question of gauge must depend on the character of the country to be passed through. In hilly districts a narrow gauge would be desirable. The question of motive power must be left to others to decide. The Board of Trade would not be justified in doing away with their requirements as to the working of a line, for the fencing, the signalling, the block system, level crossings *versus* bridges, station platforms, and the maximum of speed. The doing away with any of those requirements must be the work of the Legislature itself. Whether the light railways should go along roads or across country would be another question to be considered, and there were other matters of political economy which must not be lost sight of. Of course, the solution of many of those questions must depend on the attitude taken by the existing railways. He hoped they would recognise the great value which these proposed new lines would be to them, for they must serve as feeders to their main system.

After some discussion, the Duke of SUTHERLAND proposed the appointment of the following gentlemen, with others, as a committee to enquire into the question at issue: Sir M. Hicks-Beach; Sir B. Samuelson, Sir A. Hickman, Mr. W. Jackson, Mr. Beachcroft, Lord Claud Hamilton, Lord Cathcart, Sir C. Boyle, Mr. Hopwood, Lord Thring, Mr. W. Meik, Mr. H. Hobhouse, Mr. Acworth, Mr. Storey, Mr. Humphreys Owen, Sir B. Baker, Sir A. Rendel, Sir A. Clark, Mr. A. Siemens, Lord E. Fitzmaurice, Mr. Sellon, Mr. Channing, Sir A. Rollit, Colonel Makins, and himself. The resolution was agreed to, the committee to meet at once, so as to be able to present their report before the end of January.

Mr. JACKSON spoke with reference to what had been done in Ireland. It devolved upon him to make the arrangements for the last batch of light railways which had been constructed in that country under Mr. Balfour's Chief Secretaryship. Some of the lines there had been constructed under what is known as the baronial guarantee, and in many cases the charge was felt as a great burden by the ratepayers, who were more or less restive under it. The general impression upon his mind was that whenever the promoters could conveniently make arrangements under which a line to be constructed could be worked in connection with the adjoining or parent company, not only would it result in economy, but in the best interest of a locality. He believed there were many districts in England having an ample water supply in which it would be possible to have electric motors, and they would provide cheap means of conveyance. The gauge on light railways should be the same as the parent gauge, so that trucks coming from a farm could be shunted bodily on to a main line. There were places in Ireland where steam tramways were laid partly along the roads and partly on independent land. There were great disadvantages, however, in having railways or tramways along the roads, and those disadvantages were constantly growing. Sir D. FOX, C.E., was in favour of the question being relegated to the local authority, with consultation with the Board of Trade if necessary. He believed in the development of electricity as a means of bringing about cheap and light railways as proposed. One authority alone should decide as to the gauge to be laid down. After some further discussion, Mr. BRYCE said that many instructive and interesting points had been raised, and he was sure they would be duly considered by the committee.

THE PACIFIC CABLE QUESTION.

The report of the Earl of Jersey to the Marquis of Ripon on the proceedings of the Colonial Conference at Ottawa has now been published as a Blue-book. The following are extracts from the report in reference to the projected Pacific cable, in connection with which five resolutions were passed by the conference:

(1) "That in the opinion of this conference immediate steps should be taken to provide telegraphic communications by cable, free from foreign control, between the Dominion of Canada and Australasia.

(2) "That the Imperial Government be respectfully requested to undertake at the earliest possible moment, and to prosecute

Digitized by Google

with all possible speed, a thorough survey of the proposed cable route between Canada and Australia, the expense to be borne in equal proportions by Great Britain, Canada, and the Australasian colonies.

(3) "That it is for the interest of the Empire that in case of the construction of a cable between Canada and Australasia, such a cable should be extended from Australia to the Cape of Good Hope, and that for that purpose arrangements should be made between the Imperial and South African Governments for a survey of the latter route.

(4) "That, in view of the desirability of having a choice of routes for a cable connection between Canada and Australasia, the Home Government be requested to take immediate steps to secure neutral landing ground on some one of the Hawaiian Islands, in order that the cable may remain permanently under British control.

(5) "That the Canadian Government be requested, after the rising of the conference, to make all necessary enquiries and generally to take such steps as may be expedient in order to ascertain the cost of the proposed Pacific cable and promote the establishment of the undertaking in accordance with the views expressed in this conference."

In this connection Lord Jersey remarks:

"I should observe, in passing, that the discontinuance of the surveys was commented upon, and great disappointment was expressed by the delegates that the request of the conference of 1887 had been so imperfectly met. It seemed, therefore, to the conference sufficiently clear that the first step to be taken was a survey of the route, so that the depth and character of the ocean bed should be ascertained, the position of the various islands fixed, and their suitability as landing-stages determined.

"With these considerations before them, the conference passed the second of the above resolutions. Your lordship will observe that, whereas in 1887 her Majesty's Government were asked in effect to undertake the survey at their own cost, the conference proposes that the expense should be borne in equal proportion by Great Britain, Canada, and the Australasian colonies.

"It seems desirable that further consideration should be given to the question whether survey is necessary before actual operations are commenced. At the Colonial Conference of 1887, and in the subsequent correspondence, it was assumed that this was the case. Some doubt was expressed at the Ottawa Conference as to whether the partial surveys already made in the Pacific Ocean were not sufficient to render possible a fairly approximate estimate of the difficulty and cost of the work. This was the view taken by Mr. Lee-Smith, who stated as an illustration that when the cable on the West Coast of Africa was laid no survey was taken, but an allowance made for risks. It appears that since 1887 the scientific resources connected with the laying of submarine cables have been so improved that, given a general knowledge of the depth, a previous survey is not now always required. On this point I will quote from a printed memorandum by Mr. A. Siemens, which was communicated to me after the close of the conference. Mr. A. Siemens is well known as a distinguished member of one of the most important electrical firms in the world, and has very recently been successful in laying the last cable between Great Britain and America."

Then follows the quotation from Mr. A. Siemens's pamphlet, one of the sentences of which runs: "It may, therefore, be taken for granted that any technical obstacles which were apprehended in 1887 have now been overcome, and that the cable can be laid as soon as the financial question has been settled." Continuing, Lord Jersey says: "Her Majesty's Government will, I presume, consult their professional advisers on this point. The question was raised whether it would not be proper for the conference to endeavour to settle the route which the cable should follow. From one point of view it may seem unreasonable to ask that the route should be surveyed without suggesting what that route should be. Several routes touching at different islands in the Pacific were before the conference. As a general indication of their direction I will take two as types. One route would be from Vancouver Island to Fanning Island, Fiji, Norfolk Island to Tweedmouth in Australia. This is a distance of 6,730 miles, and if a branch is made to connect it with New Zealand, 415 miles would have to be added. This route is entirely through British territory. The second route is from Vancouver Island to an island in the Hawaiian group, thence through the Gilbert and Solomon Islands to Bowen in Queensland. This route is about 6,300 miles. But upon the whole it was felt that the balance of convenience was in favour of leaving these questions to stand over for future consideration. They appeared to depend largely on circumstances requiring expert information and advice, and the delegates thought it best to await any views or recommendations which her Majesty's Government, with the valuable professional assistance at their command, may in due course be able to offer.

"In connection with this matter the fourth resolution may be noted. It was the decided wish of the conference that the cable should, if possible, pass entirely through British territory whenever it touches the islands on the route. It was believed that the practical exigencies of the case, from an engineering point of view, might render it desirable that the cable should run from Vancouver to the Sandwich Islands, as this stretch is materially shorter than that to Fanning Island. In that case it would be desirable, if possible, that the exclusive use of one of the Hawaiian Islands should be obtained, in order that the cable might be as far as possible free from foreign control. Necker Island, which lies about 400 miles from Honolulu, has been much mentioned as a possible landing-stage, but it does not appear to be suitable for that purpose. Captain King in his report of last May to the Hawaiian Government stated 'there was no water, no trees, no grass; to support life, supplies would have to be brought to the island, including water, and the station there would be similar to that of a lighthouse.' Possibly some more suitable island might be found on the edge of the Hawaiian Archipelago. The conference was not, of course, in a position to arrive at any conclusion as to whether such an arrangement as that desired was practicable, but there was an impression that the Hawaiian Government was disposed to assist the project so as to secure for themselves the convenience of having cable connection with the rest of the world. The resolution should not as I understand be taken to mean that the conference favours the Sandwich Islands route. Whether that route, or the alternative one to Fanning Island, should be taken is left open. The resolution only expresses the desire that whatever route is adopted the cable should be under British control throughout. I believe that there is no practical difficulty in laying the cable if Necker Island or one of the Sandwich Islands be used as one of the landing-places. The greatest depth is apparently about 3,300 fathoms, and the Eastern Extension Telegraph Company have a cable laid at a greater depth between Java and Port Darwin. The Senegal-Pernambuco cable, also, is laid at a depth of more than 3,000 fathoms.

"It is, of course, necessary to look forward to the question of the probable receipts and expenditure when the line is in working order, and much correspondence from opposing points of view and interest has passed. I regret that I cannot place before your lordship a reliable statement as to the probable cost, expenses, and receipts. The figures mentioned at the conference must, from the nature of the case be problematical, and be taken subject to correction and variation. The cost of a single cable from Vancouver to Australia may be roughly put down at £2,000,000. Mr. Sandford Fleming, in his memorandum, calculated that the earnings of the cable would be, at 2s. per word across the Pacific (this would reduce charges between Australia and England to 3s. 3d. in place of 4s. 9d. as at present), £99,465 in 1898, and that there would be a progressive annual increase till in 1904 they would amount to £153,023. The interest at 3 per cent. would be £60,000, the cost of working he put at £60,000, and the renewal fund at £32,000. Thus in seven years from starting there would be a balance of receipts and expenditure. If this statement should prove correct, the liability of the guaranteeing Governments would rapidly diminish, and the undertaking would become self-supporting. The general opinion of the conference was that if the enterprise is undertaken with proper safeguards, it would entail little or no loss to the contributing or guaranteeing Governments. Of its value to commercial enterprise there was but one opinion. The delegates, some of whom have had business experience of a very practical kind, considered that, having regard to the usual difficulties of diverting trade and to the established advantages and conveniences of existing channels, it would be impossible greatly to enlarge the dimensions of traffic across the Pacific until a cable has been constructed. Telegraphic communication is now an indispensable condition of commercial intercourse, and if that communication is impracticable, or if the rates are excessive, commerce cannot thrive. It was believed that if the direct cable were constructed a great impetus would be given to the trans-Pacific trade, and that, therefore, the cable would not merely compete with the Eastern lines in respect of existing trade, but would reap the benefit of a new traffic.

"Adverting to the opinion that a duplicate cable is essential to the proper working of the communication, I must add that it would add very largely to the initial cost, and that its consideration can well be left till the present scheme has assumed a more definite shape. Great stress was laid upon the value of the line for Imperial purposes, but the question of the strategical value of the line must be decided by experts. Diverse opinions appear to have been expressed by various authorities, and I am not qualified to join in the controversy. I will only remark that I cannot understand how two different routes, one eastern, the other western, joining Great Britain and her Australasian colonies, can fail at critical moments to be more useful than one; and that it is a not unreasonable proposition that a cable passing solely through British territory and waters comparatively secure from attack, must give greater strategical advantages than lines which pass through European or Egyptian territories, with their constant liability to warlike complications. Considerable divergence of view was manifested at the conference as to whether it was desirable that the cable should be laid by the contributing Governments as a national undertaking, or by a private company with a Government subsidy or guarantee. In favour of the first alternative it may be urged *inter alia* that certain expenses, such as those of promotion, are avoided by State ownership, and that the danger of amalgamation with other companies to the disadvantage of the public is precluded; and in favour of the second, that a company would do the work and carry on the business more economically than a Government body. The difficulty of a State control under the joint ownership of several responsible Governments cannot be disregarded.

"It may be said that it would not be just for the Governments to subsidise a new and competing line. The enterprise of the Eastern Extension Telegraph Company has conferred great benefits on Australasia, to which Mr. Lee-Smith bore testimony. Whilst, however, admitting and admiring that enterprise, it cannot be conceded that it entitles the company to the cable monopoly of Australasia. The new route is not proposed from mere motives of competition, in which case her Majesty's Government would probably decline to take part, but from the conviction that commercial and Imperial interests demand its construction. The British Government pay subsidies for cables to Bermuda, the Seychelles, Mauritius, and to certain British settle-

Digitized by Google

ments and possessions in Africa. These places, it is true, were entirely without telegraphic communication before the subsidies were given, but not one affords a parallel case to that of the vast continent of Australia. The subsidy and guarantee paid by five Australasian colonies to the Eastern Extension Telegraph Company amounted in 1892-3 to £53,363."

Lord Jersey concludes by stating that further negotiations must take place on the subject of the guarantee or subsidy, after the questions of route, survey, and probable cost have been settled. He, however, repeats that an alternate line of communication with Australasia and the Pacific should have strategic as well as commercial advantages.

BEDFORD ELECTRICITY WORKS.

The electricity works at Bedford, which we described in our issue of the 30th ult., were formally opened on Thursday afternoon of last week. The ceremony of switching on the light was performed by the Mayoress, who was accompanied by his Worship (Mr. George Wells, J.P.). There were also present Alderman Young, Councillors Richards, Jarvis, Turner, Sell, and Mr. T. S. Porter (clerk). The various parts of the apparatus and machinery were explained to the Mayoress and the gentlemen present by Mr. F. H. Medhurst (consulting engineer to the Corporation) and by his staff of assistants. The Mayoress then switched on the light to four 100-c.p. lamps in the roof of the station.

Mr. Councillor Richards (chairman of the Electric Lighting Committee) said that the inhabitants of the town were getting anxious to have the benefit of the electric light, and that the committee therefore felt it their duty before waiting to put any finishing touches to the station and machinery to let the people have the light at the earliest possible moment. The station was not a show place, but a place where the work was done. It was built for working purposes, and therefore those who visited it anticipating they would see a show place would be disappointed, but they hoped to get a lot of work out of that station for the benefit of the ratepayers of the borough of Bedford. That was not the place for speaking, and he could not help thinking if they had the noise of those engines in the Council-chamber they would have had a good deal less talk on the electric lighting question. But it had not been all talk, for there had been a lot of hard work done in the last four months, and he could say that they had beaten the record in installing the electric light. It had been done in this town in a shorter time than anywhere else. That it would be a success the committee felt sure. The only fear they had at the present time was that the machinery would not be strong enough to supply the number of customers who had applied for the light. That spoke well for the opinion of the town, and was an answer to their opponents who had feared it would be a failure. The committee said it would be a success because of the manner in which the town had taken the matter up, and helped the Corporation by showing in that way that they appreciated their services.

The Mayoress then switched on the current to the town mains.

Councillor Sell proposed a vote of thanks to the Mayoress, remarking that it was fit she should do it, as the Mayor had most constantly stuck to his guns with this question.

Alderman Young seconded, and the vote was carried by acclamation. The proceedings then terminated.

LEGAL INTELLIGENCE.

GORDON V. SCOTTISH HOUSE-TO-HOUSE ELECTRICITY COMPANY, LIMITED.

This case came on last Friday for trial before Mr. Justice Lawrance, without a jury, in the Queen's Bench Division of the High Court of Justice. The plaintiffs claimed a sum of £5,000 under an agreement with the defendants dated October 4, 1892. The defendants admitted the contract, but raised a number of defences. The plaintiffs, Messrs. Gordon, were electrical engineers in London, and they entered into an arrangement with the defendants, who had a contract to light the town of Coatbridge, to do the work. The plaintiffs performed some part of their contract, but the defendants did not, and hence the plaintiffs claimed £5,000, which they alleged to be forfeited by breach of contract. Counsel then formally proved the plaintiffs' case in detail.

Mr. Crump, Q.C., for the defence, said the facts were as follows: There was a provisional order granted for lighting Coatbridge with electricity, and several gentlemen formed themselves into a syndicate for the purpose of raising the necessary funds to float and finance a company and carry out the contract to light Coatbridge. The defendant company was then in a state of suspended animation, and it was desired to resuscitate it and put the shares on the market. Accordingly, an agreement was entered into to underwrite a number of shares, and in this manner the syndicate was brought into communication with the present plaintiffs. Messrs. Gordon agreed to find one-third of the capital if the syndicate could find the other two-thirds. This the plaintiffs did not do, and consequently the £5,000 was not supplied. No work had ever been done by the plaintiffs, and as a fact the British Electric Company had carried out the whole of the contract since, as in January, 1893, the plaintiffs went into liquidation. The whole arrangement was subject to underwriting by certain persons, and as they failed to do so, he submitted the plaintiffs were not entitled to recover.

Mr. Justice Lawrance held that the defendants were not liable to pay the £5,000, and he accordingly entered judgment for them with costs.

PRIESTMAN BROS. v. STARBRICK.

On Tuesday, in the Queen's Bench Division, this case was heard before Justices Wills and Wright. It was an appeal by Messrs. Priestman Bros., of Kingston-upon-Hull, from the decision of the magistrate at Hull, who had held that a deed of apprenticeship was disadvantageous to an apprentice, and therefore void.

Mr. M. Lush appeared for the appellants, while Mr. L. Smith represented the respondent.

Mr. Lush said in 1889 the respondent was apprenticed with the appellants to be taught the trade of an instrument maker. There was a clause in the indentures providing that after the apprentice had attained the age of 18 years he should work overtime when required to do so, and should receive pay for such overtime at the rate of time and a half. On April 27 last respondent was informed that he would have to work overtime from five to nine in the evening to finish a spraymaker upon which he was engaged. He refused, and proceedings in the police court followed. It was proved that for the overtime the respondent would have been entitled to 7½d., whereas a journeyman engaged for the same period would have charged about 3s. The magistrate was of opinion that the clause of the indenture with reference to overtime was disadvantageous to the respondent, and that there was a want of neutrality in the deed, and that it was void. He (the learned counsel) submitted that the decision of the learned magistrate was wrong.

Mr. Justice Wills said he was of opinion that the clause in the indenture went beyond what was fair to the respondent, and therefore the decision of the magistrate would be upheld.

Leave to appeal was granted.

GRAHAM v. SITWELL.

On Wednesday, in the Westminster County Court, his Honour Judge Lumley Smith, Q.C., had before him the case of Graham *v.* Sitwell, in which the plaintiffs, Messrs. Graham and Riddle, a firm of electric light fitting dealers, sued the defendant, Sir George Sitwell to recover a balance of account of £6 in respect of electric light fittings supplied to his order. It appeared, from the evidence of the plaintiffs, that the defendant was in the habit of giving orders for goods from time to time and paying for them in the ordinary course, but he objected to pay for these particular goods on the ground that, although he gave the order for them, he did so on behalf of his mother, and was, therefore not personally liable to pay.

A **Member of the Firm** was called, and said he did not remember the defendant saying anything about the goods being for his mother, or that she would pay for them.

For the defence **Sir George Sitwell** was called, and swore positively that when he gave the order for these goods he told the plaintiffs they were for his mother and that she would pay for them. In spite of that, however, they insisted upon sending in accounts to him, but from the first he had repudiated his liability, and had the plaintiffs sent in the account to the proper quarter they would have been paid the money.

His **Honour**, after hearing the evidence, said he had come to the conclusion that he ought to non-suit the plaintiffs, as they had evidently got hold of the wrong person, but they could always bring a fresh action against the proper person.

COMPANIES' MEETINGS.

GENERAL ELECTRIC POWER AND TRACTION COMPANY, LIMITED.

An extraordinary meeting of this Company was held on Tuesday at the Cannon-street Hotel to consider the confirmation of the resolution passed at the extraordinary general meeting on the 21st ult. for winding up the Company voluntarily under the provisions of the Companies Acts, Mr. James Pender occupying the chair.

The **Chairman** proposed the resolution and **Mr. Immisch** seconded it.

Mr. Page Hopps thought the shareholders were entitled to a little further information regarding their position and assets before they were asked finally to wind up. They had shares in the Acme and Immisch Company and the Immisch Launch Company, and he would like to know what would be done with these shares. He did not understand how any complication could arise—as appeared to be thought at the last meeting—regarding the rights of the preference and ordinary shareholders.

The **Chairman** stated that as far as he was aware the preference shareholders had a first claim on any assets which might exist.

Mr. Garcke observed that the position of the two classes of shareholders was clearly defined, and the liquidators would have no difficulty in dealing with the matter. No arrangement whatever had been made as to selling the preference shares held by them in the Acme and Immisch Company and the Immisch Launch Company.

The motion was then carried with one dissentient, and a further

Digitized by Google

resolution was afterwards passed appointing Mr. E. Wilding (the accountant) and Mr. William Bulloch (the secretary) liquidators of the Company, and fixing their remuneration at £150.

WESTMINSTER ELECTRIC SUPPLY CORPORATION, LIMITED.

Two extraordinary meetings of shareholders in this Corporation was held yesterday (Thursday) morning. The first, which was of holders of founders' shares, confirmed the following resolutions which were passed at an extraordinary meeting held on the 28th ult.: "That out of the newly-created share capital of £100,000, £40,000 in 8,000 shares of £5 each be forthwith issued at a premium of £1 per share, and in the first instance allotted to shareholders on the register on November 14, 1894, in the approximate ratio of one to every complete eight shares then held, and that the Board be empowered to allot any balance of the 8,000 shares not alloted to the shareholders, to members of the staff of the Corporation, or to such other persons as they may think fit on the same terms. That the amount due on the shares be payable as follows: £1 (premium) on January 3, 1895; £2 on January 15, 1895; and £3 on July 1, 1895, and that the new shares rank for dividend (on amount of capital paid) from January 1, 1895. That the balance of 12,000 shares be retained, and that the Board be authorised to issue them as required, they being first offered to the shareholders on the register at the time of such issue, and on such terms as the Board may consider desirable."

The second assembly, which was of the shareholders, confirmed the following resolutions which were passed at an extraordinary general meeting held on the 28th ult.: "That out of the newly-created share capital of £100,000, £40,000 in 8,000 shares of £5 each be forthwith issued at a premium of £1 per share, and in the first instance allotted to shareholders on the register on November 14, 1894, in the approximate ratio of one to every complete eight shares then held, and that the Board be empowered to allot any balance of the 8,000 shares not alloted to the shareholders, to members of the staff of the Corporation, or to such other persons as they may think fit on the same terms. That the amount due on the shares be payable as follows: £1 (premium) on January 3, 1895; £2 on January 15, 1895; and £3 on July 1, 1895, and that the new shares rank for dividend (on amount of capital paid) from January 1, 1895. That the balance of 12,000 shares be retained, and that the Board be authorised to issue them as required, they being first offered to the shareholders on the register at the time of such issue, and on such terms as the Board may consider desirable."

WOODHOUSE AND RAWSON UNITED, LIMITED.

The debenture-holders of Woodhouse and Rawson United, Limited, met on Tuesday at Winchester House to hear a statement of the progress made in the realisation of the assets. Mr. F. D. Leslie, the receiver and manager, presided.

The **Chairman**, in the course of his remarks, said: I propose to give you a report which I have prepared, giving as clearly as possible the result of the liquidation of the assets that have up to the present been actually realised, and the estimated result of those assets which still have to be liquidated. In doing this I shall take the estimates of value based on the different groups of assets by the directors in their statement of affairs, and show you, when possible, by comparative figures, where and how the differences have arisen. I was appointed receiver and manager for the debenture-holders on March 10, 1893, and on the same date I took possession of the books, documents, papers, and assets of the Company. It took me a considerable time to thoroughly acquaint myself with the nature of the assets, and, indeed to find out where some of them were, also to obtain a full grasp of the situation. The books of the Company—in a large concern like this they were something like 200—were in anything but a complete condition, and, in fact, had not been posted since December, 1892. It consequently took many months to bring them up to the date of my appointment as receiver and manager. Of course, it was absolutely necessary that this should be done, as until this was finished I could not ascertain what were the assets of the Company, especially the book debts, or the position of the branches generally. You may be aware that this Company had agencies and branches situated in the United Kingdom to the number of 13, also at various places on the Continent, at Johannesburg and other parts of South Africa, and in Australia. Now, as these branches not only traded with the head office, but traded amongst themselves, you will see it was necessary that not only the books at the head office, but also the books at the various branches, should be written up before I could ascertain and trace the assets that ought to be at the various branches. Whilst this was being done, amongst many other things, two important matters required my immediate and constant consideration: First, the completion of the contracts entered into by the Company and only partly carried through at the date of my appointment. Of course, on account of these contracts, various sums of money had been received, but there were still considerable sums outstanding representing work already done under the contracts, and which, had the whole contract not been completed, would have been forfeited. I am glad to say that all these contracts have been completed, and no such forfeiture has occurred. Second, I had to consider which of the branches should be carried on, either with a view to the contingency of the reconstruction of the Company, and their forming with what goodwill might attach to them a valuable part of the assets to be dealt with in such reconstruction, and also to ascertain which branches were of such a nature that to carry them on at all would only involve further and serious loss. Having decided in which of these two categories the various branches must be placed, I had to take immediate steps to close down those in the second category, the carrying on of which would only have resulted in further loss. Much time was taken up in dealing with these matters, and in this connection I may say—although, perhaps, it is almost unnecessary—that in a large concern like this no serious steps could be taken without applying to the Registrar for authority to take such steps. This necessarily caused delay, as you know the Court will not make any order without the fullest information being laid before it; but at the same time it will, no doubt, be satisfactory to you to know that I have, in every case of any moment, taken such directions before acting. All the before-mentioned matters took up such an amount of time that at the end of the first six months of my trading as receiver and manager I was not in a position to take out a trading and profit and loss account; in fact, I could not do so, as I had not received, and could not receive, from the foreign branches their returns. I, therefore, decided to take out a trading and profit and loss account at the end of my first year's trading, being as at March 9, 1894. In taking out this account, and before I give you the result, I must say that the stocks on March 10, 1893, were overvalued. Upon the trading at the head offices and the branches (and, perhaps, at the present moment I need not go into the details, but may rather deal with the result as a whole), there appears a loss of £3,872, the greater part of which is accounted for by the fact that the turn-over was nothing like large enough to bear the standing charges, consisting of rates, taxes, rents, wages, salaries, etc., although in this connection I may say that immediately after my appointment, and during the whole of the time I have had the management of this business, I have given my attention to in every way cutting down the expenses. I reported to the Court and received directions to take steps to close down the head office and branches, the result of which is that at the present moment I have closed down all the branches, with the exception of the head office, Manchester, Kidsgrove Works, Birmingham, Chiswick, South Africa, and Australia, and have ceased trading altogether. I am now negotiating for the sale of the assets at the head office, also for those at the Manchester, Kidsgrove, Birmingham, Chiswick, South Africa, and Australian branches. The Official Receiver, as you are aware, issued a statement of affairs under date of December 12, 1893, setting forth therein the valuation of the various assets as estimated and certified by the directors. I have found it practically impossible to give you a detailed comparative statement of the realisation of the general assets, as in many cases sales have been effected, including items appearing in the statement of affairs under several headings, the whole being sold as a lump sum. Moreover, as the stocks mentioned in the statement of affairs at £76,396 have, of course, been depleted, it would be impossible and unfair to compare the realisation of the remnant of those stocks with the estimate of the stock on March 10, 1893. I think that I can, with the exception of the items "stock-in-trade" and "trade fixtures and fittings," give reliable figures, which items I, however, think may be fairly estimated at £20,215. The cash at bankers and in hand appearing in the directors' statement of affairs is substantially correct. The investments in shares, etc., amount to £31,768. The item appearing in the statement of affairs for property—£36,847—includes the sum of £13,500 for goodwill at the head office and different branches, and the sum of £21,950 for patents. The item for goodwill will realise nothing, but for certain of the patents I have received an offer of £2,000, others are included in the offer of £8,500 for the Manchester and London businesses, the remaining patents being valued at £1,150. The book debts were estimated to be of the value of £37,519, but I estimate a deficiency on the whole item of £24,521. The next item is bills receivable, which, according to the statement, are estimated to produce £3,662. Of this amount £1,616 has been received, and the balance of £2,046 is valueless. I now come to an item of £13,599, which is the estimated surplus from the securities in the hands of the creditors fully secured. Of this item not more than £2,500 will be received, inasmuch as it was estimated that the surplus from the sale of the Kidsgrove works would show an excess of £5,000, but it will only show £2,500, and even part of this is for stock, etc., not included in the mortgage or in the above estimated surplus; whilst from the Cadby Hall sale it was anticipated that a surplus of £7,000 would result, and this property has been disposed of by the mortgagees for £10,500, the amount of their mortgage money and interest. I may say with reference to this property that I instructed a well-known firm of land agents and valuers in the West-end of London to value the property on my behalf, and they valued it at the sum of £6,000. I thereupon allowed the mortgagees to enter and take possession. The item for unpaid calls was estimated to produce £7,647. Up to now I have succeeded in recovering £7,073, and anticipate that £100 will be realised from the remainder. After detailing certain negotiations he had entered into for the disposal of the remaining assets of the Company, the Chairman proceeded: You will gather from the report which I have read to you that the realisation of these assets has fallen far below the too sanguine estimate placed upon them by the directors in their statement of affairs. You will see that as all the assets at the present moment are not realised it is practically impossible for me to give anything like a reliable estimate of what may be expected by the debenture holders in the shape of a dividend, but my estimate is that, subject to the costs of the realisation, there will be a sum of £32,000 available for distribution amongst the debenture-holders, of which I estimate £3,600 will be due to the

Digitized by Google

5½ per cent. debenture-holders, £18,400 will due to the 6 per cent. debenture-holders, and £10,000 to the 10 per cent. "secured" debenture stock. It is apparent upon the face of it, from the statements that I have made to you, that in no case can the debenture-holders receive a full return for their investment, and although it would, of course, have afforded me greater satisfaction to have been able to give you some more or less reliable figures to day from which I could arrive at an idea of what dividend I shall sooner or later be in a position to pay you, you will see that under these circumstances all I can possibly do is to lay before you—which I think you will see I have endeavoured to do—a full account of the present position of the assets existing when I took possession of what is practically your property, and also lay before you a statement showing the steps I have taken in your behalf and in the protection of your interests.

Some discussion having ensued, the **Chairman**, in reply to the Receiver of the British Electric Lighting Company, said the amount of debenture stock outstanding on the respective issues was as follows: on the 6 per cent. debentures, £65,500; on the 5½ per cent. debenture stock, £118,187; on the 10 per cent, £19,905; but he did not anticipate more than £13,600 of the last named would rank.

The proceedings closed with a vote of thanks to Mr. Leslie.

CONTRACTS FOR ELECTRICAL SUPPLIES

CONTRACTS OPEN.

Blyth.—The Cowpen District Local Board (Blyth, Northumberland) invite tenders for the lighting, by electricity or otherwise, of the lighting area within their district by the 20th inst.

Madrid.—Tenders are invited by December 20 by the Ministère d'Outre Mer, Madrid, and by the General Government of Havana, for the construction of a telephone system in the island of Santa Clara.

Portsmouth.—The Town Council invite tenders for the purchase of certain electrical plant at the Town Hall, Portsmouth The plant has only been used about four years, and is now being sold in consequence of the Town Hall being now connected with the central electric light station. Full particulars of the articles to be sold, with forms of tender, can be obtained on application to Mr. Alexander Hellard, town clerk. A price must be given for each separate article, and the forms of tender, duly filled up, must be delivered by 22nd inst. The Town Council do not bind themselves to accept the highest or any tender, and reserve the right to accept any item or items of a tender.

Walsall.—Tenders are invited for alterations to buildings at the Wolverhampton-street gasworks, including the construction of boiler-house, dynamo-house, offices, and other works for an electricity generating station, for the Corporation, in accordance with the plans and specifications prepared by the borough surveyor, which may be seen at his office, Bridge-street, Walsall, where forms of tender and bills of quantities may be obtained Tenders, endorsed "Tender for Electricity Generating Station," to be sent to Mr. John R. Cooper, town clerk. Walsall, by 24th inst. The Corporation will not accept the tender of any firm or person paying less than the standard rate of wages current in the district.

Edmonton.—Tenders are invited for the supply, delivery, and fixing of a system of electric call bells and telephones, for fire brigade and Local Board purposes, for the Edmonton Local Board. Forms of tender and full particulars may be obtained of Mr. G. Eedes-Eachus, engineer to the Board, Town Hall, Edmonton. Sealed tenders (which must be upon the Board's form), endorsed "Tender for Electric Call Bells and Telephones," to be delivered at the office of Mr. Wm. Francis Payne, clerk, Town Hall, Edmonton, by 12 noon on 21st inst. Any person whose tender may be accepted will be required to enter into a proper contract, with bond and sureties to be approved by the Board, such contract and bond to be prepared, executed, and completed in every respect at the expense of the contractor.

Hanley.—The Corporation of Hanley are prepared to receive tenders for the supply and erection of the following plant: Contract No. 10—extension of engine-house plant, including 200-kilowatt alternator, 25-kilowatt alternator, and 20-kilowatt exciter, each separately driven by a compound steam-engine, with all necessary steam and exhaust pipes, valves, switchboard, and appurtenances; Contract No. 11—extension of condensing plant, consisting of circulating pump, air-pump, boiler pump, surface condenser, with all necessary pipes and appurtenances. The drawings can be inspected, and specifications, prepared by Mr. G. H. Cottam, Corporation electrical engineer, together with general conditions and forms of tender, can be obtained at the offices of Mr. Joseph Lobley, Town Hall, Hanley, on payment of 5s. Tenders are to be delivered to Mr. Arthur Challinor, town clerk, on or before January 5, 1895. The Corporation do not bind themselves to accept the lowest or any tender.

RESULTS OF TENDERS.

Tunbridge Wells.—The tender of Messrs. MacFarlane and Co. has been accepted by the Town Council for the supply of arc lamp standards at the rate of £9. 8s. per standard.

London.—The London County Council have affixed their seal to agreements (in duplicate) with the Post Office in respect of the maintenance, at an annual cost of £13 in each case, of telephonic communication between the Kennington fire-engine station and the Vauxhall Cross street station, and between the Rotherhithe fire-engine station and the Bermondsey street station.

Cheltenham.—The following tenders for steam and exhaust pipes have been opened by the Electric Lighting Committee of the Town Council: Messrs. Such and Larter, Cheltenham, wrought iron £73, cast iron £31; Messrs. Thomas Piggott and Co., Birmingham, wrought £35, cast £60; Messrs. Sharpe and Co., Lancaster, wrought (no price), cast £47; Mr. James Pollard, Burnley, wrought (no price), cast £47; Messrs. Edwin Lewis and Sons, Wolverhampton, wrought £125, cast (no price); Staveley Coal and Iron Company, Chesterfield, wrought £10. 10s. per ton; "Silvesters," Newcastle, Staffordshire, wrought £38, cast £30. 10s. The committee resolved to accept the tenders of Messrs. Thos. Piggott and Co. for steam-pipes, and of Messrs. Such and Larter for cast-iron exhaust-pipes.

BUSINESS NOTES.

Ealing.—The mains are to be extended.

Salford.—The price for current to be charged by the Council is 7d. per unit.

Belfast.—It is expected that the electric light will be ready for use next month.

Glasgow.—The Merchants' House Buildings are to be lighted electrically. Messrs. Anderson and Munro have obtained the wiring contract.

Jersey.—A scheme is on foot for establishing an electric llghting company in the island.

Wolverhampton.—A new theatre, the Grand, has been opened. It is lighted electrically.

Western and Brazilian Telegraph Company.—For the past week the receipts were £3,084.

Bristol.—The Roman Catholic church in Victoria-street is to have the electric light installed.

Warminster.—The Local Board are considering the question of the erection of a central electric light station.

Bangor (Wales)—A committee of the City Council are to enquire into the subject of introducing the electric light.

Llanelly.—The Local Board are making enquiries as to the probable demand by private consumers for current.

West Australia.—The Coolgardie Electric Lighting Company has issued a revised prospectus. They want £7,000.

Aston.—The Local Board consider that for the present it is undesirable to go in for the electric light for the district.

New Hirst.—The New Hirst branch of the Ashington Co-operative Society which has just been opened is lighted electrically.

Rathmines.—A committee of the Commissioners is to report on the advisability of introducing the electric light into the township.

Wells.—A special committee has been appointed by the Town Council to enquire into the subject of introducing the electric light.

Guildford.—The Urban Sanitary Authority have instructed a committee to go into the general matter of the best means of lighting the streets.

Pontefract.—A committee of the Corporation are enquiring into the question of constructing an electric tramway between Pontefract and Featherston.

London.—Extensive alterations have been made in the premises of the Royal Geographical Society, Savile-row. The electric light has been introduced throughout.

Scarborough.—The Lamps Sub-Committee of the Town Council have been instructed to obtain tenders for the lighting of certain streets in the borough by electricity.

Fermoy.—Mr. Tomlinson, engineer to the Bray Electric Lighting Company, has submitted to the Fermoy Town Commissioners a scheme for the introduction of the electric light.

Cheltenham.—Alderman Norman has been appointed chairman of the Electric Lighting Committee. The committee are about to order transformers, meters, and service conductors.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 9th inst. amounted to £855, as compared with £606 in the corresponding week of last year.

Eccles.—Alderman Kendall and Mr. Oldfield have been re-elected chairman and vice-chairman respectively of the Town Hall, Tramways, and Electric Lighting Committee of the Town Council.

Manchester.—The new parcels' offices of the Lancashire and Yorkshire Railway in Strangeways are lighted by electricity. It is being urged that the electric light should be extended to Stretford-road.

Aluminium Soldering Company, Limited.—This Company has been registered with a capital of £10,000 to acquire, develop, and turn to account certain patents for inventions relating to soldering aluminium.

Bell's Asbestos Eastern Agency, Limited.—This Company has been registered with a capital of £10,000 to enter into an agreement with Bell's Asbestos Company, Limited, and to deal in asbestos and asbestos goods.

Taunton.—The Town Council have decided to refund the sum of £25 to the relatives of the late Warren Upham, of Brixham, who was recently killed at the electric light works, being a portion of the premium paid by him.

Digitized by Google

Newcastle Tramways.—There has been a warm discussion in the Town Council, where some members favoured the adoption of electric traction on the tramways. The majority, however, supported the old principle of cable lines.

Lowcock, Hill, and Co., Limited.—This Company has been registered with a capital of £15,000 to acquire as a going concern the business of electrical engineers, etc., as hitherto carried on by Lowcock, Hill, and Co. at Manchester.

Brechin.—An arc lamp has been erected in St. Ninian's-square and was lighted for the first time last week. The lamp was erected by the Scottish House-to-House Electric Supply Company. The wiring was undertaken by Mr. Lowden, Dundee.

Fareham.—A Local Government Board enquiry has been held into the application of the Local Board for sanction to borrow £7,000 for electric lighting purposes including the purchase of the Fareham Electric Light Company's undertaking.

Chiswick.—The Local Board have approved of the plan for a new electric light station submitted by Messrs. Bourne and Grant. The Works Committee of the Local Board report that the works at the electric light station are progressing favourably.

Dover.—Another heated discussion has taken place in the Town Council on the subject of whether the streets should be lighted by gas or electricity. Eventually a resolution that the gas company have the contract for another year was carried.

Globe Telegraph and Trust Company.—The directors of the Globe Telegraph and Trust Company, Limited, have declared an interim dividend of 3s. per share on the preference shares, less income tax, and of 1s. 6d. on the ordinary shares, free of income tax.

Fulgur Electric Lighting Company, Limited.—This Company has been registered with a capital of £7 to acquire from Le Fulgur Société Anonyme d'Eclairage Electrique the patent for an apparatus for primary batteries for Great Britain and Ireland, No. 9,689 of 1891.

Oldham.—It has been reported to the Town Council that the Electric Light Committee had made enquiries as to persons willing to take the supply in various streets of the town, but the committee do not consider the demand to justify the extensions of the mains.

National Electric Engineering Company, Limited.—This Company has been registered with a capital of £5,000 to acquire and carry on the business of electrical engineers, as hitherto carried on by A. C. Cockburn and D. C. Bate, at 2, Holborn-place, W.C., and elsewhere.

New Office.—Messrs. Weyman and Hitchcock, Limited, makers of the "Trusty" engines for oil or gas, have opened an office at 11, Queen Victoria-street, E.C. This firm have recently moved into large works at Cheltenham, which are equal to an output of some 500 or more engines per annum.

Brighton.—The Town Council have adopted the report, which we printed in our last issue, recommending the borrowing of £42,000 for an extension of the electric lighting system. Councillor Berry has mentioned that the balance on the electric light works will be something like £1,000 this year.

Eastern Extension Telegraph Company.—This Company announce an interim dividend of 2s. 6d. per share for the quarter ending September 30. The 5 per cent. Australian Government subsidy debentures, due on January 1 next, will be paid on and after that date at Messrs. Barclay, Bevan, and Co.'s bank.

Glasgow.—The treasurer to the Town Council has reported that the collection of electric lighting rents on 28th November last were £3,185. 13s. 10d. for 1894-5, as compared with £2,118. 0s. 7d. for 1893-4, an increase of £1,067. 13s. 3d. The Lord Provost states that the demand for the electric light continues to increase.

Country House-Lighting.—Judging from the number of country houses Messrs. Drake and Gorham have in hand at the present time, it would seem that this class of work is far from being exhausted. Among other work, they are carrying out the lighting of Speldhurst for Mr. E. Jansen, where they are putting down a petroleum engine, dynamo, and a battery of D.P. cells.

City and South London Railway.—The receipts of the Company for the week ended December 9 were £941, against £913 for the corresponding week of 1893, or an increase of £28. The total receipts for the current period of the present half-year amount to £20,517, as against £19,188 in the corresponding period of 1893, an increase of £1,329.

Hanley.—The Town Council have decided to apply to the Local Government Board for a consent order for the creation and issue of £39,310 Hanley Corporation 3 per cent. redeemable stock for the purpose of raising loans required for wiring and fittings for the electric lighting of the public buildings, works of sewerage and sewage disposal, etc.

Aluminium and General Foundry Syndicate, Limited.—This Company has been registered with a capital of £10,300 to enter into an agreement for the purchase of the inventions and secret processes of Rudolph Van Wart for manufacturing aluminium alloys and of solder, and also of the business carried on by him at 36, Percival-street, Clerkenwell, E.C.

Sheffield.—It has been decided that the new hospital in West-street shall be lighted by electricity. Many other important consumers have been joined to the supply mains during the past few weeks, and the resources of the company to supply the demand are greatly strained. It is hoped that the company's new machinery for supplying an additional 10,000 lights will be running by the end of this year.

Halifax.—The work in connection with the Corporation electric light station is progressing under the superintendence of Mr. Wilmshurst, the electrical engineer. Last week the small engine was running daily, and the two large engines have been got into working order. The mains have been tested, and Trinity-road Baptist Chapel has already been illuminated with electric light supplied from the works.

Bell's Asbestos Company.—The half-yearly interest on the 5 per cent. mortgage debenture bonds of Bell's Asbestos Company, Limited, will be paid by warrant on and after 1st prox., also the bonds drawn on the 7th inst. for payment on the same date, at the Manchester and Liverpool District Banking Company, Limited, 75, Cornhill, E.C. The transfer-books will be closed from the 18th to 31st inst.

Harrow.—The Local Board called a public meeting last week to consider the question of electric lighting. Among those present were Mr. W. C. Hawtayne, the consulting engineer, and Mr. R. E. Crompton, the tender of whose company has been provisionally accepted by the Board. Although a motion and amendments were put to the meeting, it does not appear from the local reports that any definite decision was arrived at.

British Light Railways, Limited.—This Company has been registered with a capital of £110 in 20 £5 shares and 10 £1 shares, to construct, purchase, lease, or otherwise acquire any light railways, tramways, or tramroads in the United Kingdom, and to equip, maintain, and work the same by horse, steam, electricity, or other mechanical power; to manufacture and deal in locomotive and other engines, dynamos, and apparatus, etc.

Grasmere.—The Clerk to the Local Board has received from the Windermere Electric Light Company maps showing the line of proposed cable. Mr. Simpson said the whole matter had been left over for the new District Council. When did the time for opposing the company expire? The Clerk thought on December 24. The Surveyor thought not till January 15. It was directed that the clerk communicate with Mr. Gatey, and call a special meeting if necessary.

R. Waygood and Co., Limited.—This Company has been registered, with a capital of £60,000, to acquire and take over as a going concern the business of constructors of and dealers in lifting machinery, and of hydraulic, electrical, and general engineers and contractors, and otherwise, heretofore carried on at Robert's place, Falmouth-road, Great Dover-street, London, S.E., and at other places in the United Kingdom, under the style or form of R. Waygood and Co.

Morley.—A meeting of the Town Council has been held, when Mr. Robert Hammond, consulting electrical engineer, adverting to his offer *re* the lighting of the Town Hall, wrote that his feeling was that under the terms of the competition if the Corporation employed him to carry out the town scheme the £100 premium paid to him would merge into his fee for superintending the work. Under those circumstances he would superintend without fee what might prove to be the first instalment of the work—viz., the lighting of the Town Hall. Councillor Johnson proposed, and Councillor Foster seconded, that the letter be referred to the Town Hall Committee, which was agreed to.

Bath.—Mr. C. Chivers, at a meeting of the Town Council, asked what steps were being taken with regard to the provisional order for which the electric light company had given notice that they were applying to the Board of Trade. He had been told by those conversant with such matters that unless the Corporation stated their intention of taking the light into their own hands the company would be sure to get the provisional order they were seeking. Mr. Moore and other members hoped the Electric Light Committee were fully alive to the situation, as they wished the Corporation to take over the lighting themselves. Alderman Sturge informed the members that the committee had not forgotten or overlooked the question.

Cardiff.—A supply of current to the arc lamps in the streets was turned on at Cardiff on Monday. At the meeting of the Council in the afternoon several members called attention to the delay in lighting the town by electricity. Councillor Vaughan (chairman of the Lighting and Electrical Committee) and the Mayor explained that the Corporation had not yet taken over the system, and that experiments were still being carried on. It was the intention of the committee to extend the mains for the electric light. The committee before doing anything wished to lay specifications and costs before the Council, and if the expenditure were sanctioned the committee would be only too glad to go on with the work of extension.

Bowness.—At the last meeting of the Local Board the Chairman said they would all have seen the notice of the Windermere Electric Supply Company advertised in the newspapers, seeking for permission to lay their cables on the public roads of this district, and also on a number of private roads. The Clerk stated that, according to the rules of the Board of Trade, they (the company) could do nothing for three months. Mr. Holland said there was plenty of time to consider the plans. Mr. Westlake thought it would be as well to commence the lighting question. The clerk, after being requested, read Mr. Fowke's letter, and also his (the clerk's) reply. The Chairman then stated they would push the matter as far as they could, after which the subject dropped.

Stafford.—The Electric Lighting Committee of the Town Council recommended an insurance of the men against accident in conjunction with the insurance scheme of the Gas Committee. Alderman W. H. Peach, in moving the adoption of the report, said the chimney at the works had been completed, and the accumulator-house had been roofed. The principals were now about to be erected in the engine and dynamo house. By a joint system of insurance with the Gas Committee the premiums

Digitized by Google

payable for the insurance of the men under the Employers' Liability Act were much lighter. He was pleased to report that the County Council had determined to light the technical instruction buildings by electricity. Alderman Silvester seconded the adoption of the report, which was adopted.

Dewsbury.—Alderman Fox at a meeting of the Town Council opposed a recommendation of the Lighting and Water Committee to expend in wages for workmen at the central lighting station £468 per annum, and ultimately, by the casting vote of the chairman, it was decided to refer the matter back to the committee. On Monday the electric lighting works belonging to the Dewsbury Corporation, which have been erected on the site of the old gasworks in Bradford road, under the superintendence of Mr. W. H. Preece, of London, were formally opened in the presence of the Mayor and members of the Corporation and other public bodies. Alderman Robinson, the chairman of the Gas and Lighting Committee, performed the ceremony of switching the electric current into the distributing mains. Later on a number of shops in the town were lighted from the central station.

Hastings.—The Roads Committee reported to the Town Council last week that they had received from the Hastings and St. Leonards-on-Sea Electric Light Company notice of the intention of the company to construct a transformer-chamber under the public pavement at London-road, St. Leonards, and recommended that the plan be approved. The committee had also received from the company a communication forwarding plan of a service main intended to be laid by them under the pavement in Queen's-road, consisting of a 3in. cast-iron pipe of 9ft. lengths with clip joints, and four brick connection-boxes with pavement frames and covers, such main to be laid about 18in. from the kerb at an average depth of 18in. The committee recommended that the plan be disapproved, the same not showing fully the mode and position in which the proposed works were intended to be executed, and the manner in which it was intended to interfere with the street. The report was adopted by the Town Council.

Elmore's German and Austro-Hungarian Metal Company.—The profit and loss account shows a loss for the year ended December 31, 1893, of £12,076. The directors state that the loss on trading is made up to a considerable extent by the reduction made in the values taken of the various descriptions of copper in stock, it having been deemed desirable by the German managers and auditors that these should be written down to almost their raw material value. It is also partly made up by the loss incurred on the sale of 10 tons of stock tubes, which had to be sold at the raw copper value, instead of the market value of such sized tubes. Subject to these reservations, the actual loss on trading did not exceed £600. The largeness of the profit and loss account is partly accounted for by the fact that, according to the German company law, it was necessary to write off the establishment expenses, as shown in the last account, amounting to £4,471, as loss, and the depreciation on the various accounts comes to the sum of £3,300.

Lancaster.—In proposing the adoption of the minutes of the Gas Committee at a meeting of the Town Council, the Chairman (Alderman Hatch) remarked that the comparative statement of gas consumed during the past quarter was very much better than at the corresponding period of last year, and although they had not yet felt the pressure of the electric light, the committee were exceedingly loyal to their consumers, and would endeavour to do the best they could for them by reducing the price of gas at the earliest opportunity. Not only were they trying to do this, but they were going to endeavour to meet the wants of the poorer inhabitants by the adoption of the penny-in-the-slot meter. Probably at their next meeting this system would be adopted, and the matter would come before the Council in due course. Whether the Electric Lighting Committee would start anything of the kind he did not know, but they would endeavour to set them a good example. As soon as the Electric Light Committee could afford to pay anything reasonable in the shape of a contribution towards the rates, the Gas Committee would not be backward in attempting to follow them.

Airdrie.—Provost Arthur has moved at a meeting of the Airdrie Town Council for the appointment of a committee, to act along with a similar committee for the burgh of Coatbridge, to consider the formation of a joint trust for the purpose of laying down a line of tramways from Drumpellier in the west of Coatbridge to Clarkson in the east of Airdrie, and to work the same in the interest of the two burghs. The proposed line would be about four and a half miles long. The Provost said that such a scheme by a private company had frequently been talked about, but he strongly favoured the concern being in the hands of the Corporations, as both burghs had already suffered by the gas and water supplies being in the hands of private companies. He had no doubt that the scheme, which had the approval of the provost and others in Coatbridge, would be a remunerative investment, and a great convenience to the public. Whether the motive power would be by cable or by electricity could be dealt with in committee by the proposed trust, along with the getting of the necessary powers. Bailie Conner seconded the proposal, which was unanimously adopted, and a committee was appointed in terms of the motion.

Aberdeen.—The members of the Gas and Electric Lighting Committee of the Town Council have made their annual inspection of the gasworks and electric supply station. The Lord Provost stated that he hoped that Councillor Johnston, the convener of the committee, would have a successful addition to the plant at the electrical station, and that he might soon be able to reduce the price of the electric light to 4d. per unit. Mr. Murray (the electrical engineer) said he could assure them that it had been a great pleasure to him to see the great success of the electric lighting in Aberdeen. It had been more successful in Aberdeen than in any other city. It had never yet met with any mishap, and of very few schemes of the kind could that be said. So far as he knew, their consumers were very well pleased with the service. He only hoped that the committee would soon extend the system to the West-end, as he had every confidence—judging from the success of the past—that it would be speedily taken up. Lord Provost Stewart supplemented the remarks of Mr. Murray by stating that he knew there were a great many people in the West-end who were ready to take in the light the moment the system was extended.

Prescot.—Considerable commotion has been caused at Prescot by the action of the Local Government Board auditor, Mr. George Haslehurst, in surcharging four members of the Local Board to the extent of £360 in connection with the electric lighting of the township. The Prescot Wire Company had entered into a contract with the Local Board to light the town with electricity instead of gas, as formerly supplied by the gas company. Mr. J. D. Banks, solicitor, had complained of the inefficient nature of the new light, and further drew the attention of the authorities in London to the fact that there was no penalty clause in the contract, which rendered it invalid. Some of the members of the Board have espoused the cause of electricity and others gas, and the controversy has waxed hot locally. Acting on several minutes in the Board's records that they did not consider the lighting efficient, the auditor has surcharged four members—Messrs. Edward Dyson, James Berry, Joseph Preston, and Thomas Pennington—to the extent of £360, as they had signed cheques for payments to the company to cover periods when the light was unsatisfactory. The clerk is preparing a petition to the Local Government Board to ask them to remit the surcharges.

Accrington.—Mr. Riley at a meeting of the Town Council asked if it was intended to do anything with respect to the electric light this year. It was now over a year since a site was purchased for a central station, and he had been expecting to see a meeting called for the purpose of going on with the work. He was afraid the thing was going to be shelved again, for what reason he could not say. Neighbouring towns were introducing the light, and it was giving every satisfaction He thought Accrington ought to keep abreast with the times They either ought to decide once and for all to introduce the electric light, or let someone else come in and do it for them. The Mayor: Would you propose a meeting of the Legal and Parliamentary Committee being called? Mr. Riley: Yes; I should like a meeting. The Mayor: I will do so. Mr. E. Higham said the last time the matter was brought up the Council decided against the light being introduced, and he did not think the committee would be prepared to move unless they were requested by the Council. They brought a very definite resolution to the Council, and the Council put it entirely on one side. Mr. J. S. Higham: They referred it back for reconsideration by the committee, and they have not reconsidered it. Mr. Ratcliffe: We have bought the gasworks since then.

Leeds.—A special meeting of the Leeds City Council has been held, the Mayor (Alderman Gilston) presiding. Mr. Moody, in the absence of Alderman Firth, moved a resolution declaring it expedient that the Corporation should in the next session of Parliament promote a Bill authorising the construction of additional tramways in and near the city, and for other purposes; and, further, charging the expenses of promoting the Bill "on the city fund and city rate, or such other public funds or rates as the Council may deem advisable." This was, he said, a purely formal resolution, carrying out the decision arrived at by the Council last month. The motion having been seconded. Mr. Battle moved an amendment providing that the costs incurred in passing the Bill should be charged to the tramways account. The Town Clerk pointed out that the resolution as worded would give the Council power to determine that the expenses should come out of the tramways account. After further discussion, in the course of which the Town Clerk, in reply to Mr. Goodson, said that whilst there was no doubt the tramways account was a public fund, it might be advisable to incorporate the amendment in the resolution in order that there should be no doubt on the point, the amendment was accepted, and the resolution adopted.

Appointments Vacant.—There is required at the Manchester Corporation electric works an assistant to take charge of an eight-hour shift. He must have had technical education and passed through usual routine of pupilage; essential to have had central-station experience of boilers, engines, dynamos, secondary batteries, and switching gear. Salary £2. 10s. per week. Applications to be made in writing, with copies of testimonials, and forwarded to the Gas Department, Town Hall, Manchester, by 15th inst, addressed to the Chairman of the Gas Committee, and endorsed "Application for Assistant Electrician."—The Blackburn Corporation are about to appoint a properly qualified mechanical and electrical engineer to take full charge of the electricity works. Applicants must have an extensive experience in the construction and erection of engines and dynamos, and the working of a central station on a low-pressure system. Age not less than 26, nor more than 40 years; salary £200 per annum. Applications, endorsed "Superintendent Engineer," stating age and experience, accompanied by copies of not more than four testimonials, to be sent to Mr. Robert E. Fox, town clerk, Town Hall, Blackburn, in sealed envelope, by 15th inst. Canvassing will disqualify.—The Worcester Town Council want an electrical engineer to take charge of the electric lighting works. The salary is £250.

Liverpool.—At a meeting of the Health Committee of the Town Council the town clerk read a letter from Mr. H. P. Boulnois, city

Digitized by Google

engineer, who is engaged in London on corporate business, in reply to a letter which appeared in the newspapers from Mr. H. H. Hall, managing director of the Hall Electrical Company, Limited, complaining of the "unreasonable delay in obtaining the Health Committee's permits for service lines." The engineer, in his communication, said there was no foundation in fact of alleged undue delay taking place in granting permission for laying electric cables or services. Upon receipt at his office of plans and applications they were examined, and all the necessary enquiries were made, his report being sent in to the Health Committee generally within 14 days. Of course, between the final meeting of the Health Committee in October and the first meeting in November a longer period would elapse before the committee's approval could be obtained; but in case of urgency, provided there were no special objections to the proposed lines, he would grant provisional permission. The Town Clerk added that in his opinion the last few lines of Mr. Hall's letter contained a very serious libel, and it would be for the committee to consider whether they would take any steps in the matter. Mr. J. Houlding pointed out that the writer of the letter was only one out of the 600,000 people in Liverpool. What was the use of taking notice of every letter which appeared in the newspapers? The Chairman said the whole subject could be considered at a more opportune time by the committee.

Weston-super-Mare.—In our last issue we gave Mr. Francis H. Medhurst's report to the Local Board on the subject of refuse destructors and electric lighting. In this connection it may be mentioned that the Electric Lighting Committee's minutes of a meeting held on the 5th inst. are as follows: "In presenting to the Board the result of our careful consideration of the report of the electrical engineer on the question of electrical supply to this town, this committee desires to express its high appreciation of the ease and ability which Mr. Medhurst has exercised in its preparation, and recommends that his account be paid forthwith. In leaving to our successors the further consideration of this important question, we should like to state that the conclusions he has arrived at commend themselves strongly to our judgment. We believe the system of electric lighting could be established with small risk of loss even at the commencement, and with good hope of ultimate profit and saving to the ratepayers, to say nothing of the great advantage it would be to the town. The proposal of agreement with the Horsfall Company, containing provisions which would require careful consideration and probable alteration, commends itself to us as a very good basis for negotiations with them, and we strongly recommend it to our successors as forming a satisfactory solution of the problems of the disposal of the refuse and utilisation of the power generated by its combustion." At a special Board meeting subsequently held it was—upon the proposition of Mr. Pethick, seconded by Mr. Phillips—resolved *nem. con.* that the minutes of the Electric Lighting Committee be confirmed.

Tunbridge Wells.—The chairman of the Lighting Committee for the present year is Councillor Ashby Wood. The committee have decided to sink a well for the supply of water to the electric lighting station, and Mr. Prince has been authorised to proceed with the work provided the cost does not exceed £60. It has been decided to employ a clerk of works to superintend the laying down of the electrical machinery and plant at a salary of £3 per week. The tender of Messrs. MacFarlane and Co. for the supply of arc lamp-posts has been accepted, their tender being £9. 8s. per post. The offer of the gas company to lay a gas service from the Quarry-road to the central station, with a branch to the adjoining stables, for £32. 10s., has been accepted. The proceedings of the committee having been confirmed at a meeting of the Town Council last week, Councillor Putland asked what it was intend to lay the gas service to the central station for? Councillor Wood said they proposed to have a gas-engine to do the work in the daytime, and they required gas for the purpose of working it. The proceedings of the committee were then adopted. The Lighting Committee reported at the same meeting that they had had under consideration the question of the arrangements to be made with the gas company for the lighting of portions of the town after the electric lighting works are established. The committee thought it desirable that the contract with the gas company should be revised. The contract is determinable by six months' notice. The electric lighting of portions of the town will, it is expected be in operation before June 24 next, and the committee, therefore, recommended the Council to authorise them to determine the present contract with the gas company, and to make arrangements with them for a fresh contract, subject to the approval of the Council. A motion for the adoption of the report was agreed to.

Larne.—At an adjourned meeting of Larne Town Commissioners the following letter relative to the removal of an arc lamp-post at the corner of Inver and Bank roads was read: "To Mr. William Baxter, town clerk. Dear Sir,—Messrs J. E. H. Gordon and Co. have informed us that, owing to the improvements made at the corner of Inver and Bank roads, the post bearing the arc lamp has been considered an obstruction by your Commissioners and by the county surveyor; that the county surveyor has written them to have the post removed or otherwise he would institute proceedings. Messrs. Gordon further state that they laid these facts before your Board, and on the 22nd ult. wrote you fully on the subject, pointing out that they would be bound to comply with the requirement of the county surveyor and remove the lamp-post, but that without the authority of your Board they could not put it in any other position, and that accordingly the corner would be left in darkness until your Board saw fit to direct a new position for the lamp. Notwithstanding this latter, we are informed that your Board have passed a resolution to the effect that our clients and the county surveyor should be left to settle the matter between themselves. Now, we beg to give you notice that when Messrs. Gordon are compelled to remove the lamp-post by the county surveyor they will not undertake the responsibility of placing it in any other position until your Board directs where it is to go. Accordingly, the corner will be left in complete darkness, and Messrs. Gordon will not admit any liability, seeing that the fault entirely lies with your Board. It is a very trifling matter, and our clients are anxious that there should be no litigation on the subject. Accordingly, you will kindly direct your Lighting Committee to give the necessary directions.—Yours faithfully, M'NEILL AND WILLIAMS, solicitors, Larne." The letter was marked read.

Smithfield Club Show.—Messrs. Robey and Co., of Lincoln, make a prominent exhibit at Stand No. 1 at this show, which closes to-day, at the Agricultural Hall, Islington, N. One engine shown is a horizontal engine fitted with their automatic triple-expansion gear. This engine is of substantial construction, suitable for doing heavy work, and is at the same time provided with expansion gear for securing the greatest economy in fuel and perfect governing under varying loads. On an estate it can be set to do thrashing, sawing, and other work in the day time with the greatest economy, and at night can be employed for driving a dynamo for electrical illumination. A compound Robey engine and locomotive boiler combined, fitted with an automatic governor and link expansion gear, is also on view. This class of engine is suitable for driving electric light plant, mills, factories, and other machinery where perfectly steady running is required. In addition to the above, Messrs. Robey exhibit specimens of their medium and long stroke horizontal fixed engines, fitted with automatic governor and link expansion gear, portable engines, and wrought angle-iron framed thrashing and finishing machines, steel-framed stone-breakers, centrifugal pumps, and high-speed vertical engines. This type of vertical engine is specially suitable for driving dynamos and other high-speed machinery either by belt or by being coupled direct. All the wearing parts have very large surfaces, and as the crank runs in a bath of lubricating mixture it, together with all the bearings, is automatically lubricated, so that long runs can be secured without needing to stop the engine. Among other exhibits may be mentioned a horizontal fixed oil-engine, which has internal automatic ignition, and is able to develop the greatest power for the size of cylinder. The governors control the engines with great efficiency and regularity, and the engines work with great steadiness, and can be used for electric lighting.

Acton.—The Local Board received a letter from Mr. J. Clifton Robinson, the manager of the London United Tramways Company, asking the Board to receive himself and Mr. Winslow, the manager of the Leeds electric tramway, in support of the company's petition for the consent of the Board to their provisional order to authorise the reconstruction of the line between Shepherd's Bush and Acton and the introduction of the overhead trolley system of electric traction. Mr. Amherst said he thought the Board should defer the settlement of the question until after the election of district councillors. The Chairman, in reply to a question, said that the company proposed to carry the tramway as far as Acton-hill. Mr. Bradford observed that the Board had previously received a strong deputation of tradesmen and others in opposition to a proposal to carry the tramway through the town. Several members expressed opinions adverse to the settlement of the matter prior to the election, and Messrs. Robinson and Winslow, on being introduced into the Board-room, were informed that as that was the last meeting of the Board but one, the Board felt that the questions of overhead wires and a continuation of the tramway should be left for the District Council to decide when elected. Mr. Robinson said that if the Board had any fear of dangers arising from the overhead system of electric traction, Mr. Winslow, who had had great experience of that system, would be pleased to answer questions on the subject. The Chairman replied that as the Board would not decide the question discussion would be out of place, but if Mr. Winslow could attend before the District Council they would be very glad to see him, he was sure. The deputation then withdrew. The Chairman, referring to a remark made by Mr. Bridger Athawes in a letter published in a local paper, said that the Acton Board were invited to visit Havre to see the working of the electric tramway there, but they distinctly declined the invitation.

Keswick.—The clerk read to the Local Board, at a meeting last week, the minutes of a special meeting of the Board at which it was resolved to instruct Mr. I. Lowthian, solicitor, to report upon certain proposals of the Keswick Electric Lighting Company as contained in a letter read at the meeting. The Chairman mentioned that Mr. Lowthian had drawn up a report, which was as follows: "I have examined the Electric Lighting Acts, 1882 and 1888, and the Board of Trade rules with reference to a proposed application by the Keswick Electric Light Company to the Board of Trade for a license and provisional order under the above Acts The company have hitherto distributed their light principally by above-ground wires and on sufferance, and now wish to obtain a legal status, with right to lay mains under the streets and other privileges and duties, as set forth in the printed forms of license and provisional order, the latter being the more elaborate form. The method of proceeding would be by memorial to the Board of Trade, stating the description and capital of the company and other particulars, and requesting to be relieved from the obligation of supplying light during the whole 24 hours—*i.e.*, during daylight; and proceedings can be commenced to obtain the license at any time, and as to the provisional order, in July next, followed up by

Digitized by Google

advertisements limiting the time for objections. The consent of the local authority to the application is a preliminary, and the most convenient method for putting the facts before the authority seems to be to submit to them the draft memorial when it is ready; and in the meantime enquiry could be made as to the needs of probable customers of the company who might otherwise be put to trouble and expense in opposing. A piecemeal or partial consent, to be followed by another consent, does not appear to be contemplated by the law. The consent must be given by a resolution passed at a meeting of the local authority held after previous notice of the same, and of the purpose thereof, has been given in the manner in which notices of the meetings of such local authority are usually given. Since writing the above Mr. Jos. Broatch, the company's solicitor, has handed me a draft notice of the intended application for a provisional order to submit to the authority, which draft, though not so full as the draft memorial and order would be, gives a further instalment of information. It appears that the company wish to proceed with certain works this winter, and if so, the authority would have to consider whether they would consent to that course without the license or order being first obtained, or security given by the company to obtain one of them without delay." Mr. Lowthian then read the terms of the provisional order. Mr. Hogarth asked if the Board were in order in entertaining the application. The Chairman said sufficient notice had been given as far as he was aware. Mr. Broatch (the clerk), who is solicitor to the electric light company, said the Board of Trade would insist upon proper notices being given even if they got the consent. They would have to give notice by July 1. They wanted the consent of the Board to enable them to get on with their work. After considerable discussion, the Local Board decided that the matter should stand over for the Urban Council to deal with.

Southport.—The following minutes of the Electricity Committee were read at a meeting of the Town Council on Tuesday: "November 20.—Resolved, that it be referred to the Works and Plant Sub-Committee to consider the desirability or otherwise of providing electricity for motive power and street-lighting, and the best means of increasing our present supply for private consumers, and that they be empowered to take such measures (including the taking of expert opinion) as they may deem necessary or advisable to enable them to present a complete report to this committee. December 4.—The engineer reported that the plant at Crowlands was capable of supplying current to 5,200 8-c p. lamps; that 3,198 lamps had been connected to the mains; that 2,146 lamps were at present unconnected; and that applications had been received for an additional 620 lamps. Resolved, that new applicants for current be informed that save under exceptional circumstances the committee cannot for the present connect their premises to the mains, and that a circular letter be issued stating that the committee propose to at once put down additional plant to meet the demand, and inviting intending consumers to make immediate application, and informing them that they will be connected in rotation according to the dates of their application. Resolved, that the town clerk be instructed to communicate with the Local Government Board with respect to the proposed extension of the works." Councillor Hesford, in moving the adoption of the minutes, said that they were perfecting and completing the system as rapidly as they could. They would see that the Board of Trade had consented to the further delaying of the statutory opening of the electricity works for three months from the 27th ult. That meant that on March 27 next they must be in a position, unless a further period of delay was granted, to place the current on the main for the whole 24 hours of the day. Up to the present time they had as good a report of the electric works as the Gas Committee had to lay before them. The number of lamps and the amount of current were increasing, and applicants were far in excess of the power of supplying the electric light. Their machinery was supposed to be capable of supplying about 4,200 lights. They had applications for 6,000. And in face of this the committee had decided that the new applicants for the current could not at present be supplied, except in certain exceptional cases, and these were the churches and chapels, which they wanted to take the light on the Sunday, so that they could have a Sunday load. At present they were connecting shops and places of business chiefly. They would see that they had Prof. Kennedy at their works, and so far as they knew they would not require broader or wider buildings for the purpose of extension. They must remember that the slightest disarrangement of their delicate machinery might place them in the position of asking some of their customers to be cut off. As to the finances, they stood, so far as their estimates were concerned, in strong contrast to the Improvement Committee. They had, however, powers for £28,000. Of this they had expended about £14,000—just about half—and so far as they could see they would not exceed the whole sum allowed. He believed there was some truth in the statement that the Corporation had not touched the fringe of prospective applications for the light. Councillor Todd seconded, and the motion was carried.

Worcester.—The Electricity Committee of the Town Council reported having elected Mr. G. H. Williamson as chairman for the ensuing year. They recommended the fixing of an electric arc lamp at each side of the Guildhall gates at a cost of £47. 10s. Mr. Williamson moved the adoption of the recommendation, and upon Mr. Rushton enquiring how many more extras they would get, Mr. Williamson replied that at every meeting of the Council they would bring up as many extras as they possibly could, consistent with the development of the scheme. The recommendation was adopted. The committee submitted a special report recommending the appointment of an electrical engineer, versed also in the management of machinery driven by steam and water power, to take entire charge of the installation at Powick and in the city, and to be directly responsible to the Council and the committee. They also recommended that the salary should be fixed at £250 per annum, and that the committee should be empowered to define the duties, advertise for applicants, and recommend three for the Council to select one of them. Mr. Williamson moved the adoption of the recommendation. He urged that they could all see the absolute need of having a competent electrical engineer, on whom they could thoroughly depend. Mr. Millington seconded, remarking that the subject of the electric light was of such importance as to demand the undivided attention of a competent person. In reply to Mr. Bozward, Mr. Williamson said the Council were under an agreement with the Brush Company to take over the works on January 11. Mr. Barnett stated that when Mr. Caink's salary was increased the Council were led to understand that he would take over the responsibility of the electric light works. This proposed appointment seemed to be sprung upon them. Mr. Williamson pointed out that Mr. Preece recommended the appointment of two officers—one at £200 and the other at £180 a year—so that the proposal of the committee was less costly. He believed that within two years the committee would be able to tell the Council that the business was thoroughly established and paying them well. Mr. Hughes supported Mr. Barnett's suggestion as to Mr. Caink's electrical knowledge being put forward as an argument for his appointment as city engineer, and said he did not think the Council should be hurried into the appointment of a fresh officer. The Sheriff said that the statement of the city engineer's duties included the control and responsibility for the due working of the electricity works. The committee had decided that a much better arrangement would be to have another engineer, and it would be open to any member to suggest a re-arrangement with regard to Mr. Caink's salary. Mr. Winwood enquired whether Mr. Preece's services would end when the Council took over the works? Mr. Williamson replied that he hoped so. It was impossible for the city engineer to carry out the whole of the work in addition to his ordinary duties, so as to make the £60,000 fruitful. Alderman Day urged that if they did not give the committee the authority they asked for, possibly in two months everything would be in utter chaos at the electricity works. The surveyor was responsible for the works in a way, but only as far as general supervision was concerned, and it was absolutely necessary he should have an efficient staff. In reply to Mr. Charge, the Mayor said the increases of capital outlay had not been made without due notice being given. Nothing would please him better, if they could see their way to making a decent return of interest, than to go in for another £10,000 or £15,000 increase of capital. If they could get a good return for their money, the more they put out the better it was for everybody. The resolution was passed.

Canterbury.—The town clerk read the following letter from the Brush Electric Lighting Company relating to the number of ordinary gas lamps which would be replaced by the arc lamps: "49, Queen Victoria-street, London, November 24, 1894—Dear Sir,—Electric Lighting of Streets—I have gone carefully into this question with Mr. Baker, your surveyor, and forward you by this post the Ordnance maps of the city of Canterbury, on which I have marked the position of the proposed arc lamps, and shown by an enclosing blue line the number of gas lamps which each arc lamp would replace. Unfortunately, owing to the narrowness and crookedness of your streets I find that the average number of gas lamps so replaced to be under three for each arc lamp, although in some parts of the city where the streets are straight and fairly wide one arc lamp sometimes replaces as many as five gas lamps, including one large Sugg or Bray lamp. The total number of arc lamps shown upon the plan is 47, which are distributed over the following streets: St. Dunstan's (commencing at London-road), Westgate-street, St Peter's-street, High-street, Parade, St. George's-street, St. George's place, Chantry-lane, part of Longport-street, Church-street, Monastery-street, Lady Wooton's Green, Lower Bridge-street, Broad-street, Church-street (No. 2), Palace-street, Guildhall-street, Sun-street, Mercery-lane, and Burgate-street, which between them take up 36 arc lamps, replacing in all 99 gas lamps. In the district on the other side of High-street, I have marked the position of 11 arc lamps along St. Margaret's-street, Castle-street, Rhodaus Town, Upper Bridge-street, and Dane John. These 11 arc lamps replace 30 gas lamps. By reference to the map it will also be seen that a few more arc lamps in the space between Dane John and Castle-street, and six or at most seven lamps in the space between Burgate-street and St. George's-street, practically replaces the whole of the gas lamps within these areas, and if desired I will mark the best position of these arc lamps upon the maps if they are returned to me for that purpose, although for the present my instructions from Mr. Baker are that only the lighting of the streets enumerated above is to be estimated. The price we would propose charging for arc lamp burning all night long every night in the year is £30 each, or if the lights be extinguished at midnight we would make the price £25 each per annum, provided a 14 years' contract is entered into between the Corporation and the company. The minimum number of lights which we would be prepared to supply and maintain would be 33, placed as shown in the positions marked on the map, or at such adjacent points as may be selected by the Council. Taking the total number of gas lamps therefore which would thus be replaced as 129, their average illuminating power as being about 12 candles, and the price to the Corporation for each gas lamp as being £3. 13s. 6d. per lamp from sunset to sunrise the whole year round, the cost of gas

Digitized by Google

lighting thus replaced would be £474. 1s. 6d. plus the additional cost of the large Sugg or Bray burners, say £30, making the total probably about £500, while the cost of current for the 47 arc lamps replacing them would be £1,410—or about 26 times the volume of light for less than three times the outlay for gas lighting. Were a larger area taken, the expense of arc lighting would appear more favourable in comparison, as in other parts of the city the average number of gas lamps which could be replaced by each arc lamp would be greater. I trust the information which I now place before you will enable your Council to favourably consider the question of entering into a contract with the Canterbury Electricity Supply Company, and thus secure the introduction of electric lighting into your city. I append a list giving the number of each arc lamp as marked upon the plan, and the gas-burners which each would replace.—Yours truly (for the Canterbury Electricity Supply Company, Limited), A. J. LAWSON." The Town Council have resolved to consider the letter six months hence, the mover of this resolution giving as a reason that the electric light would be cheaper by-and-by.

PROVISIONAL PATENTS, 1894.

DECEMBER 3.

23398. **Improvements connected with electric batteries.** Robert McLauchlan McDonald and Alexander McDonald, 70, Wellington-street, Glasgow.

23441. **Improvements in and connected with galvanic batteries.** John Crisp Fuller and George Fuller, 33, Chancery-lane, London. (Complete specification.)

23440. **Improvements in or relating to targets and electrical indicators therefor.** Alfred Mantel-Rieter and Emanuel Meyer, 323. High Holborn, London. (Complete specification.)

23472. **Improvements in telephony and apparatus connected therewith.** Charles Adams-Randall, 1, The Avenue, Bedford-park, London.

DECEMBER 4.

23480. **A combined mat and electric alarum contact.** James John Pye, 27, Martin's-lane, Cannon-street, London.

23486. **Improvements in or relating to secondary batteries or accumulators.** Francis Louis Berners and Frederick Griffin, 69, Fore-street, London.

23294. **Electric alternate-current quasi-polarised relays, indicators, and cut-outs.** Silvanus Phillips Thompson, Morland, Chislett-road, West Hampstead, London.

23505. **Improvements in electric light fittings.** James McFarlane, 154, St. Vincent-street, Glasgow.

23510. **Burglar-proof electric fastener and combination lock.** Alexander Dalziel, 41, Stanhope-street, Glasgow.

23525. **Improvements in or applicable to electric switches.** Charles Phillipp Ehmann, 70, Deansgate, Manchester.

23529. **Improvements in connections for electric lighting and power.** George Lyon and Henry Bevis, 73, St. Stephen's-road, Upton Park, London.

23553. **Improvements in apparatus for the electrical treatment of beer or other liquid or material.** Louis Wagner and John Marr, 115, Cannon-street, London. (Complete specification.)

23565. **Improvements in apparatus for transmitting and controlling work for an electrometer.** Arthur Bergtheil and Robert Alfred Marples, 1, Queen Victoria-street, London.

DECEMBER 5.

23661. **Improvements relating to electric telegraph automatic transmitting and receiving instruments.** Joseph William Wilmot, 24, Southampton-buildings, Chancery-lane, London.

23668. **Improvements in electric impedance or choking coils.** William James Davy, 40, Chancery-lane, London.

23669. **Improvements in or connected with the electro-deposition of zinc upon iron.** The Cowper-Coles Galvanising Syndicate, Limited, and Sherard Osborn Cowper-Coles, 47, Lincoln's-inn-fields, London.

23679. **Process for the manufacture of metallic articles by electro-deposition.** La Société des Cuivres de France, 53, Chancery-lane, London. (Date applied for under Patents, etc., Act 1883, Sec. 103, May 22, 1894, being date of application in France.)

23680. **A process of an apparatus for making compressed electrolytic copper, applicable also to other metals capable of being deposited by electrolysis.** Alexander Melville Clark, 53, Chancery-lane, London. (La Société des Cuivres de France, France.)

23685. **An improvement in brackets for telegraph poles.** Siemens Bros. and Co., Limited, and George William Perry, 28, Southampton-buildings, Chancery-lane, London.

23688. **An improved charging material for galvanic elements.** Gustav Platner, 37, Chancery-lane, London. (Complete specification.)

DECEMBER 6.

23697. **Improvements in the construction of electrodes.** Arnold Beaumont Woakes, 78, Harley-street, London.

23745. **Improvements in electricity meters.** Georg August Julius Telge, 31, Southampton-buildings, Chancery-lane, London. (Complete specification.)

23748. **Improvements in or connected with dynamo-electric machinery.** Francis Murray Newton and Tom Hawkins, Norfolk House, Norfolk-street, London.

DECEMBER 7.

23825. **Improvements in electric arc lamps.** James Brockie, 33, Chancery-lane, London.

23854. **Improvements in systems of electrical distribution.** Reginald Wood, 28, Southampton buildings, Chancery-lane, London.

23858. **Improvements in the construction of instruments for measuring electric currents.** Francis Henry Nalder, Charles William Scott Crawley, and Alfred Soames, 24, Southampton-buildings, Chancery-lane, London.

DECEMBER 8.

23866. **Automatic electrical fog signal.** Tom Thompson, 3, Chester-terrace, Lady Pit-lane, Leeds.

23936. **Improvements in electrical fire and burglar alarms.** John Ronald Shearer, 28, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1893.

21958. **Electric lighting apparatus for bicycles, etc.** Lake. (Mayr.)

1894.

690. **Electric railway signalling apparatus.** Hampson.

916. **Electrical measuring instruments.** Harrison.

923. **Electric fuses.** Deakin.

1115. **Electrical circuits.** Essinger and Harden.

2800. **Incandescent electric lamp fittings.** Soleau.

3080. **Fixing electric call bells.** Theerman and others.

12972. **Electric arc lamps.** Doubrava and Donat.

17313. **Electric motors.** Losch and others.

19191. **Galvanic batteries.** F. and N. von Alimonda.

19517. **Indicating the lamp hours of electric lamps.** Wende.

19742. **Electrical switches.** Theermann.

NOTES.

Electric Lighting in Switzerland.—A project is on foot for the erection of a central electric light station in Schwanden.

Electric Light Legislation in India.—An Electric Lighting Bill is being drafted, and will be introduced early in the Calcutta season.

Electric Light in Siam.—It is expected that the principal thoroughfares of Bangkok will be lighted with electricity almost immediately.

Electric Traction in Italy.—Mr. Cattori, an Italian engineer, proposes to construct, in conjunction with Messrs. Armstrong, an electric tramway in Rome.

Telephony in Ceylon.—Experiments have been made in telephoning along the telegraph wires between Trincomalee and Colombo, and have proved successful.

Bordeaux Exhibition.—The council of the London Chamber of Commerce have nominated an influential committee to consider the subject of British representation at this exhibition.

Gohna-Hurdwar Telegraph Line.—Orders have not yet been issued for dismantling this line, which will remain until the local government consider that the necessity for it no longer exists.

Berliner Telephone Patent Declared Void.—The United States Circuit Court in Boston gave its decision on Monday in the suit against the Bell Telephone Company. It declared the Berliner patent, valued at £500,000, void.

"Electric Power."—Our American contemporary will change its form on the 1st prox. It has hitherto been published monthly in the usual style of American technical papers, but it will henceforward be of the character and shape of a monthly magazine.

A New Kind of Tax.—Baron Sonnino, the Italian Minister of the Treasury, has made his financial statement in the Chamber of Deputies. He announced that there would be a small tax on the consumption of gas and the electric light by private persons.

Advantages of the Electric Light.—A pamphlet bearing the title of "The Electric Light Supplied from Municipal Works" has been prepared by Mr. R. Hammond, M.I.E.E. It deals with the advantages of the use of this illuminant and the conditions and cost of supply.

"L'Electricien."—Our French contemporary announces that on January 1 its editorial and publishing offices will be removed from 3, Rue Racine, to 18, Rue des Fossés-Saint-Jacques, Paris. All business communications are in future to be sent to M. Louis de Soye, at the latter address.

Ceylon-India Telegraph Cable.—A new cable is to be laid directly between Ceylon and India. The Ceylon Government, it is believed, is bearing half of the cost. The old cable is worn out and subject to breakdowns, and the service can only be preserved under a host of difficulties.

Telegraphy in Africa.—A Reuter's cablegram from Cape Town says that, according to advices received there from the Chinde River, the Portuguese persistently obstruct the permanent extension of the trans-continental telegraph across Portuguese territory in the direction of Tete. The work is consequently at a standstill.

Telephony in Russia.—Sebastopol and Simferopol have just been connected by telephone, which has been attached to the telegraph poles on the railway. It is expected that the Kieff military district will be connected with the naval dockyard at Sebastopol by the beginning of next spring, as the work is now being rapidly carried on.

Lectures.—Prof. Fleming has delivered a Gilchrist lecture at the Corn Exchange, Bedford, on "Magnets and Electric Currents." The lecture has followed very appropriately close upon the opening of the central electric light station there.—A lecture was delivered on Saturday evening at Toynbee Hall by Sir F. Pollock on "Tyndall as a Worker and Teacher."

Royal Society.—It is announced that a paper by Lord Rayleigh and Prof. Ramsay on a newly-discovered gas will be taken as the subject for discussion at a meeting on January 31, which will be the first meeting under a resolution of the council passed last session, whereby certain meetings—not more than four in each session—are devoted each to the hearing and consideration of some one important communication.

Prize Competition.—The Société Industrielle d'Amiens offers for the year 1894-95 gold medals for the following: a mechanical or chemical generation of electric current fulfilling the most efficient and economical conditions; a feed-water heater, to be cheap, simple, compact, and requiring little attention; and the best electric light installation which has been in operation for at least a year in an industrial works, which must be more economical than gas.

Personal.—The Government of India has recommended that Mr. Brooke, Director-General of Telegraphs, be granted an extension of his term of office, but the matter is one which has to be decided by the Secretary of State.—It is reported that Prof. G. Forbes, F.R.S., who has been engaged for the last three years on the carrying out of the scheme for the utilisation of Niagara Falls, left New York on Saturday for England by the "Campania," the construction stage of the work being now finished.

Presentation.—The employés of the Brighton and Hove Electric Light Company had a smoking concert on Monday night, this being the last concert held under the auspices of the old company, which has now closed its works, having transferred the whole business to the Corporation. Mr. George Spencer Hawes, the secretary and general manager of the company, presided, and was presented with an illuminated address, together with a handsome marble clock and side ornaments, by the employés of the company and friends.

Electric Traction in France.—Mr. Albert Sénéchal is forming a limited company for the construction and working of an electric tramway from Nice to Cimiez, for which he has received a concession. The work will be carried out by Messrs. Georges Averley and Jules Weitz, of Lyons. The line will be over three miles in length, and will be similar to that which was built in connection with the Lyons Exhibition.—The local authorities of Gérardmer, Vosges, have under consideration a scheme for an electric tramway between Gérardmer and Retournemer.

Electric Lighting in Spain.—German electricians are busy in Spain. At Baracolda, near Bilbao, Messrs. Schuckert and Co., of Nuremberg, have erected an alternating-current station using 600 h.p., which supplies current to Portugalete, Sestao, Luchana, El Desierto, Lorroza, etc.—The Allgemeine Elektricitäts-Gesellschaft, of Berlin, have come to an arrangement with capitalists in Seville to introduce the electric light into the town. The station will be in three sections, and capable of supplying current to 10,000 16-c.p. lamps, with 5,000 lamps in reserve.—Smaller stations are also being erected in Spain by Messrs. Siemens and Halske and the Oerlikon Works.

Lighting of the Stock Exchange.—The *Pall Mall Gazette* on Saturday sympathised with the Stock Exchange

Digitized by Google

on the unsatisfactory nature of the electric lighting arrangements. The arc lights at present in use are, it is said, both insufficient in number and deficient in reliability. A strong white light alternating with intense black shadows is not conducive to raising the spirits of the bulls, however much it may suit the more melancholic temperament of the bears. But, after all, there seems to be something appropriate in this weird kind of illumination. It illustrates, the *Financial Times* remarks, the startling "lights and shadows," to quote the first-mentioned paper again, of speculative life.

Electric Lighting in Calcutta.—The contract for lighting the Columbia Skating Rink was secured by the India Rubber, Gutta Percha, and Telegraph Works Company. The plant consists of a Silvertown compound-wound dynamo having an output of 104 volts and 120 amperes at 700 revolutions per minute, and is driven by one of Messrs. Marshall, Sons, and Co.'s 10-h.p. double-cylinder portable engines. Round the skating surface there are eight lamps of 300 c.p., and two in the centre of the building of 600 c.p. The offices, skate-rooms, refreshment bars, and retiring-rooms are lighted by 16-c.p. lamps, of which 42 were required. At the main entrance there is an ornamental iron pillar supporting a 600-c.p. lamp. The whole of the work was carried out under the superindence of Mr. Walter A. Purdom, A.M.I.E.E.

Postal Telegraph Service.—A deputation of Liverpool postal telegraphists has waited upon Mr. J. H. Stock, M.P., with the object of gaining his assistance in procuring an independent parliamentary enquiry into the Post Office. Mr. T. May Smith introduced the deputation, and it was explained that an independent enquiry was now sought, because official investigations had been fruitless. The improvements demanded were in the direction of better pay after attaining efficiency as operators, abolition of classification, increase of maximum salary, and alterations in the pension system. Details were given showing that the wages paid in the telegraph branch were below those paid in private enterprises and on the Continent. It was argued against classification that it existed only in regard to salary, but that classification of work was impossible.

Engineering Laboratory for Glasgow.—A meeting of gentlemen interested in the proposal to establish an engineering laboratory for Glasgow University was held in the City Chambers, Glasgow, on Tuesday, for the purpose of taking steps for raising the £12,500 necessary to fulfil the condition of the offer of from £10,000 to £12,500 by the Bellahouston Trust. Prof. Barr explained the scheme, and in suggesting the appointment of a committee he said he had in view not only the raising of funds, but the bringing of the applied science department of the university into closer touch with the engineering practice of the district. After discussion, an influential committee was appointed, with Sir William Arrol as chairman, Mr. Robert Gourlay as treasurer, and Mr. Alan E. Clapperton as secretary. Subscriptions to the amount of £3,750 were announced.

Electric Traction in Switzerland.—It is proposed to construct an electric tramway from Interlaken railway station to Gsteig-Wilderswyl. Power will be taken from the central electricity works at Interlaken.—A scheme is also on foot for an electric tramway from Schwyz to Brunnen, Axenstein, and Schwyz to Seewen.—It is proposed to establish an electric tramway between Zofingen and Aarburg, current being obtained from the central station at Ruppoldingen.—A Reuter's message, dated 19th inst., from Berne says that the Swiss Council of State, by a large majority, have granted a concession for the construction of a mountain railway up the Jungfrau, starting from near Lauterbrunnen, and ascending by way of the Little Scheidegg, over the Eiger and the Moench. The assent of the National Council to the concession is assured, and it is stated that the capital for the new undertaking has already been found, chiefly in England and America.

Laying of New Mains.—The London County Council have received intimation from the Vestry of St. Pancras of a proposed extension of the Cobden sub-station in High-street, Camden Town, and of the proposal of the Vestry to lay mains in Kentish Town-road, Fortess-road, Highgate-road, Euston-road, Drummond-street, Melton-street, Gray's-inn-road, Pentonville-road, Endsleigh-gardens, Gordon-square, Tavistock square, street, and place, Compton-street, Regent-square, Sidmouth-street, Chalk Farm-road, Harmood-street, Clarence-road, Camden-road, Great College-street, Pratt-street, and King's-road. Notice has also been given by the Notting Hill Electric Lighting Company of intention to lay mains along a very short portion of Pembridge-villas; by the Metropolitan Electric Supply Company of intention to lay a low-tension main across Sardinia-street and along that thoroughfare, Kemble-street, and Russell-street to the Drury-lane Theatre; and by the London Electric Supply Corporation to lay distributing mains in Marshalsea-road.

Central-Station Lighting.—The fortnightly meeting of the Liverpool University College Engineering Society was held last week in the lecture theatre of the Walker Engineering Laboratories, the president, Prof. H. S. Hele-Shaw, occupying the chair. There were also present: Messrs. T. Dunkerley, M.Sc., F. G. Baily, M.A., A.I.E.E., T. Farmer, B.Sc., J. G. Armour, M.I.M.E., J. W. Anderson, M.I.M.E., and W. Donaldson. Mr. B. H. Collins, A.I.E.E., secretary of the Liverpool Electric Supply Company, read a paper entitled "Central-Station Lighting in Liverpool," with special reference to the Oldham-place station. The paper included descriptions of the boilers, engines and dynamos, switchboard and connections, accumulators, transformers, and mains, and was illustrated by diagrams and lantern views. One of the most striking features of the paper was the portion that dealt with the development of electric lighting in Liverpool, which showed that in 1883, when the company started, they only supplied 120 lamps. They now provide over 30,000.

Coherer Phenomena.—The attention of Dr. Oliver J. Lodge having been directed to some observations of Prof. Elihu Thomson and of Dr. Wm. J. Morton, published in the New York *Electrical Engineer*, he has written to that journal as follows: "Their explanation of the observed facts appears to me well founded. It is quite true that a loose carbon contact will act as a coherer, though in my experience only as a delicate and troublesome one. Carbon, like platinum and gold, makes far too good a contact usually without any electrical stimulus, so that a more oxidisable metal does better. I have not found anything stand better in the long run than iron. Brass in air, though at first extremely sensitive, deteriorates with age, becoming too much oxidised apparently, and so making too bad a contact, whereas brass in hydrogen, at first incredibly sensitive, gets too clean ultimately, and declines to make anything but a perfect contact. But iron seems to perennially keep not oversensitive, but very dependable and easy to work with."

Snowdon Railway.—The first sod in connection with this railway was turned at Llanberis on Saturday. The construction of the line has been taken in hand by a limited company, the chairman being Lord Alexander Paget. Sir Douglas Fox is the engineer, and the contractors are Messrs. Holme and King, of Liverpool and London.

Digitized by Google

Before deciding upon the character of the line, the engineer and the directors studied the latest enterprises of Swiss engineering. The gauge will be 2ft. 7½in., the curves never being sharper than four chains (264ft.) radius, and the gradients never steeper than 1 in 5½. In Switzerland the gradients often approach 1 in 2, and curves are sometimes as sharp as 100ft. radius, curves of 150ft. radius being common. The "Abt" system will be adopted in the main. Steam will be the motive power at first, but if a steady supply of water power can be obtained, it is said that electricity will be eventually adopted. The stations will be four in number—two terminal and two intermediate. The line will be about five miles in length, and will be completed by July 1 next.

The Scott Electric Flashing Lamp.—After a trial extending over two years, the Scott electric flashing lamp, says the *Western Morning News*, has been pronounced by the Admiralty as unsuitable for the naval service. This lamp, an invention of Colonel Scott, was introduced into the navy with a view to testing its efficiency as a masthead signalling lamp. It was supplied to the battle-ships "Ramilles," "Royal Sovereign," "Rodney," "Sans Pariel," and "Trafalgar," the cruisers "Æolus" and "Spartan," and the signal schools at the home ports. It was desired that the lamp should give distinct intermittent flashes by means of metallic jalousies. It has been found, however, that the delicate mechanism necessary to work the jalousies, although giving the desired results during a short trial, becomes disabled when the light has been burning any length of time on account of the expansion due to heat. The reports sent to Whitehall from the ships mentioned differ only in detail, and after careful consideration, the Admiralty have directed that the Scott lamps now in use are to be returned to the makers, and they will be replaced by the multiple fibre electric flashing lamp.

Light Railways Committee.—Further meetings of this committee have been held at the Board of Trade under the chairmanship of Sir B. Samuelson. A circular letter has been issued by the secretary of the Royal Agricultural Society of England to the members of that society referring to this conference. It being desirable that the agricultural aspects of the question should be fully considered, the council desire to receive any suggestions which the members may have to offer on the agricultural light railway requirements of any particular district in which they are interested, and a schedule of questions is given to which answers are desired. These questions are as follows: "(1) please state county or counties to which the subjoined observations apply; (2) district to be agriculturally developed, naming terminal towns, places, or stations; (3) description of light railway considered most suitable; (4) the main line of railway, if any, with which a suggested light railway should have connections; (5) how funds for construction and equipment might possibly be provided—by local subscription, by rates, or advances on the security of rates, or by a combination of these sources or otherwise; (6) any other observations likely to prove useful for the purposes of the enquiry."

The Lighting of Mines.—Mr. Charles Latham has delivered a lecture at the University College, Nottingham, on "The Lighting of Mines." In speaking of electric lighting, he said he was quite at a loss to understand the reason why the electric lamp in a portable form had not come into more general use than it had up to the present time. The want of a good lamp could not be the cause, as there were several good ones on the market. It had, he knew, been urged as an argument against the use of such lamps that, owing to the fundamental principles on which they were founded, the light burnt independently of the surrounding atmosphere, and so gave no indication of its nature and character. This, to his mind, was a very strong argument in days gone by, but was it so to-day, when they remembered the inventions of Mr. A. H. Stokes and Dr. Clowes, whereby flames of alcohol in one case and hydrogen gas in the other had been successfully applied for the purpose of accurately testing the nature of the air in the mines? The use of hydrogen gas as a testing flame in his opinion marked the commencement of a new era in connection with colliery lighting, and he saw no reason why the miner of to-day should not obtain the advantage of the good light offered to him by electricity.

Testing Incandescent Lamps.—Continuing his series of articles in *L'Electricien*, M. A. Bainville raises the question as to how an incandescent lamp should be tested. The author seems to think that lamps should be tested on the spot—that is, in the installation where they are to be used—and that this is the only method which is likely to give absolutely certain results. Of course, much time is required for this, and if it is desired to ascertain the luminous power of the lamps special appliances are necessary. These reasons have caused those testing methods to prevail which mostly do not fulfil the conditions of practice, but which allow of a comparison between different makes. The author attaches much value to laboratory tests, which, serving to define the relative value of the lamps, should be made according to a uniform plan. M. Bainville states that the essential qualities that an incandescent lamp should possess are (1) constant lighting power, (2) maximum duration, and (3) minimum cost. Unfortunately, the first of these qualities does not exist in any artificial source of illumination. The second quality may be defined as the initial luminous power maintained for a maximum time, whilst the third corresponds to the production during the defined duration of the maximum candle hours for a determined expenditure of electrical energy.

Technical Education in London.—The Lord Chancellor, on Monday, distributed the certificates to the winners of scholarships and exhibitions awarded by the Technical Education Board of the London County Council. Sir John Hutton, chairman of the London County Council, presided, and among those present were the chairman of the Technical Education Board, the chairman of the Scholarships Sub-Committee (the Hon. E. Lyulph Stanley), Sir Henry Longley, Sir F. Abel, Sir Owen Roberts, and Sir P. Magnus. Sir John Hutton, in opening the proceedings, referred to the great services rendered to the cause of technical educational in London by Mr. Sidney Webb, and to the admirable work done by the zealous secretary of the Board, Dr. Garnett. Out of 61 candidates for senior scholarships five were successful, and out of 348 candidates for intermediate scholarships 50 were successful. The advance made recently in the direction of technical education was proved by the numbers of those who competed. The Lord Chancellor, after delivering the certificates, addressed the students and urged them not to rest content with the successes they had already attained. The scheme which the London County Council had framed was, in his opinion, calculated to be of immense service to the community, and to produce for the commercial life of this country results out of all comparison with the value of the money spent upon it.

Manchester Electric Light Works.—A meeting has been held of the Manchester Association of Students of the Institute of Civil Engineers, when Mr. C. H. Wordingham, A.M.I.C.E., read a paper describing the Manchester electric lighting works. Mr. A. Ross, M.I.C.E., president of the association, occupied the chair. The author first referred to the interest excited among

Digitized by Google

engineers by the Manchester electric supply on account of its magnitude and importance, and more especially because the five-wire system decided upon by the engineer, Dr. John Hopkinson, F.R.S., M.I.C.E., was entirely new in this country, and had not been largely used either in Europe or America. He stated that after rather more than a year's working, Dr. Hopkinson's boldness has been fully justified, and it was interesting to note that the St. Pancras Vestry are on the point of converting their three-wire into a five-wire system. He described in detail the arrangement of the five-wire system and the method of working the same, comparing the method and arrangement of the two and three wire systems. He next explained the system of mains and the method of running the conductors, and the switching arrangements, passing on to a description of the dynamos, engines, boilers, and coaling arrangements. The author stated that up to date 55,700 incandescent lamps reckoned in the equivalent of 8 c.p. each, 311 arc lamps, and 11 motors have been connected to the mains, and that the number of applications at present is very large. Considerable extensions are contemplated for next winter, and there is every indication that this will be the largest municipal station in the kingdom.

Electric Motors on Men-of-War.—Some months ago the *Times* gave a description of two high angle fire gun mountings and turrets of her Majesty's ship "Centurion," and in March the trial on board the "Barfleur" of similar mountings, with the addition of electromotors as an auxiliary power to the hand gear, was reported. It was then stated that the pattern was new as regards our navy, the "Centurion" being the first ship fitted with high angle fire. The battle-ship was commissioned in February for the China station as the flagship of Admiral Sir E. R. Fremantle. During her commission the system has been further tested in the course of the ordinary quarterly practices with the regular crew, and a report received by the Admiralty states that the results both as to working and shooting have proved very satisfactory, and also in comparison with hydraulically - worked mountings. Sir Joseph Whitworth and Co., the constructors of the mountings, have similar sets in hand for the "Renown," building at Pembroke, which will thus be the third ship fitted with this particular type of mounting for 10in. breechloaders. The system, the *Times* concludes, has found great favour because of its independence of steam and hydraulic power and ready manipulation by simple hand gear. The four 12in. breechloaders on the "Magnificent," which was launched on Wednesday at Chatham, can be worked by electric or hydraulic power. The guns weigh between 46 and 50 tons. It may be mentioned that some such system has been adopted in the United States navy, according to the designs of Mr. Ward Leonard, a well-known electrical engineer who visited this country a few weeks ago.

South Staffordshire Tramways.—"Great regret and surprise is being expressed to-day," says a local paper of Saturday's date, "at the course of events in connection with the South Staffordshire Electric Tramways. Quite suddenly the cars have stopped running to-day, greatly to the inconvenience of the thousands of passengers who have been accustomed to use the lines, and at present it is a matter of speculation whether the service will be renewed. The hope on all hands is that some arrangement will be come to speedily by which the cars will be permitted to run. The lines extend over eight miles—from Bloxwich to Wednesbury, through Walsall, and from Darlaston to Walsall. The conditions which led to the change from steam to the electric power will be remembered by the public, as well as the hearty reception which was given to the electric cars when they took the place of the cars propelled by steam. The new departure was a most important one, and formed quite an historic event. It met with the approval of the public, and since the adoption of this system of overhead electric traction the traffic has increased enormously. The regularity, punctuality with which the cars have run, together with the increased comfort to the passengers, testified to the great superiority of this form of motive power over that of steam. No such result as that which occurred to-day was expected by the public. The cause of it is set forth in a notice which has been caused to be published, and which reads: 'The public is informed with regret that in consequence of the failure of the tramway company to pay the contractors the agreed price of running the electric cars, although it collects the fares, the contractors have given notice to put an end to their contract on Friday, the 14th current.' The contractors referred to are the Electric Construction Company, who gave notice of their intention on Tuesday last to the directors of the South Staffordshire Tramways Company. As the payment had not been made, the contractors have taken possession of their plant." The position of affairs is further referred to in our legal columns.

Electric Traction in Germany.—A general meeting has been held of the Grosse Berliner Pferdeeisenbahn-Aktien-Gesellschaft, at which it was stated that the question of introducing electric traction on the lines of the company in Berlin had not yet been determined.—It is proposed to make an electric tramway line in the Saar district to connect Brebach, Burbach, Völkingen, St. Johann, and Saarbrück.—Work is to be commenced next spring by the Union Elektricitäts-Gesellschaft in connection with the Elbing electric tramway.—The electric tramway between Bochum and Herne has now been put into operation. This is a line the want of which has been felt for 10 years past. The work was carried out by Messrs. Siemens and Halske, who have employed the overhead trolley system. The line is a trifle over four miles in length, and was completed in 4½ months. The generating station is in Bochum, the engine being of 75 h.p. An extension of the line through Bochum to the Bergisch-Märkisch railway station is already projected.—The local authorities have approved of the adoption of electric traction on the whole of the system of the Nuremburg-Fürth tramways.—At Dresden both the horse tramway companies have received authority to use electric traction on their lines. Current will be taken from the central electricity station. On the lines in the centre of the town an underground system has to be adopted, but outside this special area overhead conductors can be used.—On account of the increased demand for current from the Aix-la-Chapelle central electricity station, owing to the establishment of the electric tramway, the works will be extended at a cost of £16,600.—The local authorities at Regensburg have received two schemes for the construction of a line of tramway.—A proposal has been brought forward for the conversion of the Plagwitz-Leipsic horse tramways into an electric line.—Experiments are being made by Messrs. Siemens and Halske with accumulator cars on the lines of the Gross-Lichterfeldt tramway, Berlin.—Messrs. Schuckert and Co. propose to construct an electric tramway from Wiesbaden to Sonnenburg.—A project is on foot for the construction of an electric tramway between Frankfort-on-the-Maine and Homburg.

Brilliant Electrical Illumination.—Those who took the opportunity a year ago of visiting Electric avenue, close to the Brixton station of the London, Chatham, and Dover Railway, will well remember the beautiful effects produced by the special illuminations during Christmas

Digitized by Google

week. At any time the lighting of the avenue is far superior to that found in any other streets, and on the occasion to which we refer the effects were magnificent. We are glad to learn that this year a similar attraction will be provided. Commencing on Tuesday evening this week, the display will be continued to and including the 24th inst. The lighting of the street will be produced entirely by Fyfe-Main arc and Edison-Swan incandescent lamps, which combined will exceed 100,000 c.p. The colonnade of the avenue will be decorated with trees, and the pillars supporting the new covered way will be entwined with foliage; festoons of incandescent lamps, representing water lilies, will be artistically looped across the roadway. In addition, there will be a number of trees fronting Brixton-road, illuminated with lamps enclosed in flowers of the same kind, only different in colour. Some colours quite different to those hitherto seen in public illuminations will be used, and the combination of these with the colours ordinarily employed for lighting effects will produce the most striking and artistic electrical illumination yet seen in any thoroughfare, either public or private. The avenue will form one vast stage, where at stated times in the evening the most beautiful prismatic effects will be created by the constant changing of the coloured lights, thereby producing results both startling and beautiful, and giving the public additional proof of the unique possibilities of electricity. The result will, it is expected, be the most charming outdoor illumination ever seen, and will form at some future time a good example of how to decorate and illuminate London on the commemoration of any national event. The decorations and electrical effects were originated and planned by Mr. A. L. Fyfe, of Brixton, and were carried out under his personal supervision. It is expected that the average number of visitors to the avenue will greatly exceed that of last year, which was more than 100,000 in one day.

Electric Lighting in Germany.—Next year at the Royal Theatre, Hanover, the electric light will be installed in place of gas.—The Plauen authorities have approved of an agreement with Mr. L. Uhmann for the erection of a central electric light station for the town.—Work has been commenced on the Olten-Aarburg central station.—A central electricity station has been built at the Munich central railway station. Current is supplied for lighting stations and railway workshops. The electrical plant has been supplied by Messrs. Siemens and Halske, and the mechanical plant by Mr. J. A. Maffei, of Munich. In connection with the Munich municipal station, the tender of Messrs. Felten and Guilleaume, of Mülheim, has been accepted for the electric light cables at the price of £15,000. The conductors for the electric tramway will be supplied by Messrs. Obermeier, of Nuremberg, for the sum of £2,000.—A central electric light station has been erected at Horb, Würtemberg, and is giving much satisfaction. The work has been carried out by Messrs. Wilhelm Reisser and Co., of Stuttgart.—Steps are being taken to provide a central station for Bingerbrück. All the leading manufacturing firms have signed a guarantee, and negotiations are in progress with a Frankfort firm for the supply of the plant.—The electric light has been installed in the Stadt Theatre, Regensburg. The electrical plant has been supplied by Messrs. Schuckert and Co., and the Lutzky gas-engine by Messrs. Klett and Co., of Nuremberg.—The local authorities at Grünhainichen propose to erect a municipal electric light station, and to borrow £3,500 for the purpose. Some interest is being shown at Oppenheim with respect to the establishing of a central electricity station for lighting and power purposes, and Mr. Kunz, of Messrs. Schuckert and Co., has visited the town and given a lecture on the subject.—It is intended to extend the central electric light station at Breslau, the whole of the output of which is now utilised.—The Munich Municipality have voted £100,000 for an extension of the electric lighting of the streets. The existing installation comprises 210 10-ampere arc lamps and 66 five-ampere arc lamps. The water power of the Isar is to be utilised. It is intended to add 456 10-ampere lamps and 48 five-ampere lamps. The work will be carried out by Messrs. Schuckert and Co., of Nuremberg.—The Esslingen Machinery Works will erect a central electric light station for the Municipality of Freudenstadt, at a cost of about £9,700.—The Gorlitz Brewery Company will light their premises electrically.—Owing to the increased demand for current, the plant at the Berlin Electricitätswerke is to be extended, and two new steam dynamos, each of 1,200 h.p., are to be erected.

Electric Power from Peat.—In the current issue of the *Nineteenth Century* is published, from the pen of Mr. J. Munro, C.E., an article on "Electricity from Peat." After asking whether something cannot be done to help the Highlands and Ireland, the author makes the following suggestions: "We cannot spare the Highlanders, and something should be done to keep them in the country. Can we not employ electricity, which has changed the prospects of so many places, to the advantage of the Highlands? The fishermen of Loch Fyne are trying to get a light railway from Strachur to Kilmun, in order to place their fish on the Glasgow market in the morning and the London market in the evening of the day on which they are caught. Here is a case in which electricity might play a part, for there is water power in the neighbourhood to drive the trains. Some time ago I was talking of this very matter with Prof. G. Forbes, F.R.S., and he asserted that he would undertake to run all the railways of Scotland by means of the water power which is now running to waste. Apart from the railways, some of the electric power might be applied to industrial purposes if there were raw material on the spot. There is, however, another source of prosperity in the Highlands and Ireland which has been too much neglected—namely, peat. In peat we have at once a fuel and a raw material, and what I desire to point out is that by burning it in engines we can obtain not only the power required to manufacture the raw peat, but also a supply of electricity for distribution. A fuel as well as a raw material, peat can supply the power required to coke, distil, and manufacture itself. For convenience and economy the associated industries ought to be carried on at the peat beds, which should be connected by rail or water with the best markets. We are now witnessing the rise of a new industrial city at Niagara, in which the machinery will be driven by electric power derived from the falls, and we may yet see the Bog of Allen or the Moor of Rannoch supporting settlements and factories for the utilisation of peat. The soil reclaimed by the removal of the peat could be brought under cultivation with fertilisers made from the peat or the sewage of towns—for example, the muck now dredged from the Clyde and flung into the sea. It is also a question for horticulturists whether fruit and vegetables could not be forced under glass on a large scale with the help of peat fuel, peat mould, and the electric light in thick weather, after the manner of the late Sir William Siemens. Moreover, just as in the case of Niagara, where electric power is to be sent by wire to the city of Buffalo, so in the Highlands and Ireland it could be distributed to work railways, and to the nearest towns or villages; and Oban, Inverness, or even Glasgow, might derive both light and energy from what is now the dark, inert, and dismal Moor of Rannoch."

THE PROSPECTS OF ELECTRIC TRACTION.

The last meeting of the Institution of Electrical Engineers was conspicuous for two especial features: the first of these reflects disadvantageously to some inconsiderable extent upon the Council, in so far as the limited arrangements made for discussing no less than three distinct papers concerned with the all-important subject of electric traction, could hardly fail to crowd out an enormous amount of useful knowledge and opinion. This was felt by many of those who were present, and it is much to be hoped that an early opportunity will be given for another discussion upon the subject of electric tramways and traction generally, so that some practical action may be taken by the members to support and foster progress in this direction in every possible way.

Electric traction is at present, so far as the country is concerned, in a somewhat critical condition, and the sooner this is realised the better it will be. No one, of course, will have the least doubt as to the ultimate issue; but unless the electrical industry bestirs itself not only to maintain present developments, but greatly to increase them against all obstacles of whatever type, there seems a by no means remote possibility that the building and equipment of electric lines will only begin to afford profitable occupation for our children's children after the generation of to-day has vanished into dust or senility.

This fact bears upon the second of the two noteworthy features above mentioned—viz., the almost unanimous feeling amongst the members of the Institution in favour of the overhead trolley system as being by far the best and cheapest in every way. This opinion was admirably voiced by Prof. S. P. Thompson and by Mr. Ferranti, and it would be well for electric traction prospects if their speeches found an echo in the minds of outsiders as well as of those more particularly interested in electrical matters. It is, however, just this particular method or system which has the hardest battle to fight—the battle against foolish and ignorant prejudice, which objects to anything new largely because it is new, in the usual unreasoning and absurd manner.

Consider first the general position of tramway companies to-day. The majority of them have not a very long life to look forward to; thanks to the Act of 1870 a limit—far too short—is put upon their powers, which in very few cases will be exceeded. This renders it almost impossible for the companies to entertain the idea of spending large sums upon converting their method of operation from the use of horses to any form whatever of electric traction, even for the advantages of greatly-increased receipts and diminished expenditure: there is no security that their powers will be sufficiently extended to enable this outlay to be recouped. The enormous advance in late years of municipal enterprise emphasises this condition, and makes it less likely than ever that the tramway companies will obtain reasonable renewals of their present powers or leases. Efforts will, of course, be made to remedy this state of affairs and secure a more favourable position for tramway companies who may still obtain leases of systems, and for all new lines yet to be built, in the enquiry now being held respecting the better development of light railways and tramways, and much depends upon the result or practical outcome of the movement as to whether or no tramways shall exist under conditions more agreeable to modern ideas, and equally fair to all concerned. On the mere matter of length of lease alone there seems no reason why tramways should be on a different footing to that of electric lighting enterprises, which in many cases obtain powers for the maximum term of 42 years when leased to private interests.

It may be taken as absolutely certain that for the future the men to convince of the advantages and profits of electric traction are more particularly the municipal engineer and the town councillor, and, failing them, the elector, who is their master. As the leases of a tramway system fall in, the local authority will, in nine cases out of ten, purchase the lines on the general terms now finally settled. In probably five cases out of the ten, given parliamentary sanction and precedent, there will be a clamour from the constituency that the local authority shall also work the lines. What, then, will be the result? It has been shown that there is no particular inducement for tramway companies (even supposing them financially capable of doing it) to adapt their lines for electric traction: hence they will fall into the hands of the local authority equipped as now, probably with horses. In all the five cases above assumed, it is almost certain no change whatever would be made. The local authority also has no particular incentive to work the tramways in a better or more effective way, especially when it means a large capital outlay; and unless public opinion grows so strong and the public demand so vigorous that quicker and more modern systems must be considered, the whole question of improvement is certain to be postponed *sine die*. This is just what has happened in Glasgow; it is just what threatens to be the case in London unless the County Council should happily follow better advice. So long as a small—even minute—profit is made, the ratepayers are not likely to object at the outset to the employment of horse traction, as at Glasgow and Plymouth, or steam-engines as at Huddersfield. To propose anything better means that the ratepayers must all dip their hands into their pockets and pay for the advantages of better traction methods. Of course, this has had to be done in the case of municipal electric lighting stations; but these have all been put down absolutely *de novo*: they do not merely involve modifications in gasworks. It is notoriously more easy in many cases to introduce a wholly new system than modify those now employed.

With existing tramways but little change for the better can be made until the local authority obtains possession of the system (which may not be for some years), and even then only by convincing the members and constituency of the enormous advantages of electric traction.

The foregoing remarks apply to the use of electric traction methods in general for tramway working, but the difficulties become still greater when the question of installing an overhead trolley system is proposed. Even at the present time, before actually entering into possession of the lines, some local authorities have shown strong objections to the tramway companies themselves spending their own money on a change of this kind, so short-sighted is Bumble! It does not seem to be realised that the lines thus equipped will at the expiry of the lease fall into the municipality's hands in far better condition, with much increased profit-earning capacity, than if merely left to their previous state of melancholy horse service! There can be no fear of extra compensation to pay for the change, inasmuch as the terms of transfer are exact, and lean, if anything, to the side of the local authority.

The chief points which the advocates of electric trolley wires must be prepared to meet and overcome are these, and although electrical engineers may doubtless feel the entire force of their utter absurdity, it must be remembered that to some minds they present a very vivid reality.

First, there is the "ugliness" of the overhead wire. Mr. Carruthers-Wain has answered this objection by stating as a fact that the South Staffordshire people do not consider the beauties of the Black Country to have been seriously affected by the use of a trolley wire! The same remark applies in slightly lesser degree to London, Manchester, and all other large centres of industry and population.

One curious thing to take notice of is this—we are told that trolley wires are unendurable in towns from their hideousness, but would prove eminently suitable for country roads. Without denying the latter assertion, the want of logic in thus bringing the trolley face to face with Nature, whilst forbidding contact with the artificial, is too prominent to pass by. But this argument is answered best of all by pointing to the continental towns and cities, admittedly far more picturesque and beautiful than our prosaic manufacturing centres of England. How do Manchester, Liverpool, Bradford, Leeds, Bristol, Newcastle, Birmingham, and a host of other such places compare in point of municipal adornment or architectural grace with Dresden, Genoa, Milan, Hanover, Brussels, and another equally large host of continental towns? Yet all these enjoy the benefits of trolley-wire lines, not merely along country or suburban roads,

Digitized by Google

but right through the heart of each place and along the principal streets; many of these are too narrow in places to allow of trolley poles, so that cross wires are strung across the roadway from building to building. It is time this bogey of æstheticism was laid to rest effectually and finally. We pride ourselves on being practical, yet refuse the benefits of rapid transit because of so-called appearances!

If these appearances may be so far trodden upon as to allow the laying down of such inartistic things as tramway rails upon a street, it will wound their feelings but very little more to have a light wire hanging gracefully high up from ornamental poles, that also serve to carry the electric lamps for street-lighting.

Another point sometimes brought forward as involving a serious objection to the trolley wire is that of possible danger to passers-by should the wire, or any part of the overhead equipment, suddenly give way and fall down upon the road, and fears have also been expressed that injury may result from shock through possibly defective insulation. Both these suggestions are to all intents and purposes absolutely groundless; with regard to bodily shock, the pressure generally adopted—from 300 to 500 volts—is not enough to do any real injury whatever, whilst it suffices to keep the mischievous from meddlesome interference with the line or equipment. Of course, the most careful precautions are taken with the overhead gear and with the car equipment to prevent any possibility of passengers ever coming into contact with the main circuit, although there are doubtless some who suppose the entire car to be filled with loose electricity, roaming about in a most unscientific and unnatural manner. As for the question of trolley wire breakage, whatever may have happened under the haphazard method of working formerly employed, especially in the United States, there need be no fear now of such incidents occurring in a manner to do any harm at all. In fact, the majority of those companies empowered to use overhead wires would be quite ready, if it was a necessary condition for the use of the trolley system, to hold such powers on the terms that they should expire at short notice if, say, half-a-dozen accidents be caused by wire breakages. Can a steam tramway say relatively as much?

A third objection brought forward is this: the trolley wire, being not more than 20ft. or 22ft. above the street surface, might conceivably prove an obstacle to the progress along or across the street of a fire-escape when required for the sudden emergency of a fire. It is doubtful whether the clumsy ladders on wheels which are thus dignified by the name of fire-escapes, prove of material service in the average fire; too often they seem to be locked up, or attendantless, or are brought even under present conditions at such a comparatively low speed along the streets by a couple of men that their use for instantaneous service may be considered almost valueless in comparison with a good rope ladder, or iron staircase, such as is built outside all well-designed large buildings. The proper remedy, however, for such a state of things is very obvious, assuming the existence of the obstacle thus referred to in the trolley wire. Actual experience on this point has proved no hindrance at all, but we may assume it for argument's sake. If the fire-escape in its present form cannot pass through the streets where trolley wires are employed, then its form had better be altered at once, and this can be done with manifest advantage, moreover, to its usefulness as a means of saving life and property. Light portable ladders, mounted flat upon trucks or wagons, and drawn by men or horses at a rapid rate through the streets can reach a fire wherever it may be in half the time required for a clumsy and top-heavy wooden staircase to be pushed along; they are easily put together in a few seconds, and placed exactly where wanted with much less trouble than occurs now with the ordinary apparatus. It may, however, be mentioned that in some continental cities the ordinary fire-escapes are fitted with arrangements for running them horizontally, and thus they overcome this objection.

It will tax the ingenuity of man to discover any further objections than those above detailed to the use on city streets and roads of a trolley wire for purposes of rapid transit, but the ignorance upon this subject is so profound, and the corresponding prejudice against the system so great in consequence, that the entire electrical industry may well take in hand the preservation of the interests of this one branch, because it is a most important one, and involves the prosperity of all the others, directly or indirectly. We have said but little or nothing as to the advantages of overhead trolley wires, beyond the prime fact that their use enables a line to be operated at half the cost of horses; but the municipalities will be well advised if in this instance also—just as with the question of electric lighting—they send deputations to those towns already in possession of trolley systems, in order to ascertain the results and merits of this method from unbiassed and disinterested sources.

Meantime it behoves the electrical industry to take active steps for promoting the development of trolley wires for electric traction in towns and cities, and this could be effected advantageously by means of a special committee or association, which should collect the necessary material and information for enlightening the ignorant or inexperienced, and see to this being put in an authoritative manner before the men especially empowered to help or hinder the equipment of electric tramways.

PRACTICAL NOTES ON DYNAMO CALCULATION.*

BY ALFRED E. WIENER.

(Continued from page 690.)

(*b*) *Bore of Pole-pieces.*—The diameter of the pole-pieces, or the bore of the field, d_p, is given by the diameter of the armature core, the height of the armature winding, and the clearance between the armature winding and the pole-pieces:

$$d_p = d_a + 2 \times (h_a + k_{12}) \quad . \quad . \quad . \quad (104)$$

d_a = diameter of armature core, in inches;
h_a = height of winding space, including insulations and binding wires, in inches;
k_{12} = clearance between external surface of finished armature and pole-pieces, in inches (see Table XLVIII.).

The latter dimension, which is to be taken as small as possible, in order to keep the air-gap reluctance at a minimum, ranges between $\frac{1}{32}$in. and $\frac{7}{16}$in., according to the kind of the armature and its size. Table XLVIII. may serve as a guide in fixing its limits for any particular case:

TABLE XLVIII.—Radial Clearance for Various Kinds and Sizes of Armatures.

Diameter of armature, in inches.	Radial clearance, k_{12}, in inches.					
	Smooth armature.					Toothed and perforated armature.
	Disc or ribbon core.			Wire core.		
	Wire wound.		Copper bars.	Wire wound.	Copper bars.	
	Drum.	Ring.

,, 4	3-64	1-32	—	1-16	—	1-32
,, 8	1-16	3-64	—	3-32	—	3-64
,, 12	3 32	1-16	1-16	1-8	1-16	3-64
,, 18	1-8	3 32	5-64	5-32	3-32	1-16
,, 24	5-32	1-8	3-32	3-16	1-8	5-64
,, 30	3-16	5-32	1-8	7-32	5-32	3-32
,, 40	—	3-16	5-32	1-4	3-16	1-8
,, 50	—	7-32	3-16	9-32	7-32	5-32
,, 75	—	1-4	7-32	5-16	1-4	3-16
,, 100	—	9-32	1-4	5-8	5-16	7-32
,, 125	—	5-16	9-32	—	—	1-4
,, 150	—	3 8	5-16	—	—	9-30
,, 200	—	7-16	3-8	—	—	5-16

The above table shows that with toothed and perforated armatures the smallest clearance can be used, a fact which is explained by the consideration that the exteriors of these armatures offer a solid body, and may be turned off true to the field bore. From a similar reason wire-core armatures need a larger clearance than disc-core armatures, since the former cannot be tooled in the lathe, and

1,500	—	—	244,000,000	195,000,000	163,000,000	130,000,000	97,500,000
2,000	—	—	275,000,000	220,000,000	183,000 000	147,000,000	110,000,000

have to be used in the more or less oval form in which they come from the press. Since copper bars can be put upon the body with greater precision than wires, a somewhat larger clearance is to be allowed in the latter case. Finally, a drum armature, in general, has a higher winding space than a ring armature of same size; the unevenness in winding will, consequently, be more prominent in the former case, and therefore a drum armature should be provided with a somewhat larger clearance than a ring of equal diameter.

The figures given in Table XLVIII. may be considered as average values, and in specially favourable cases may be reduced, while under certain unfavourable conditions an increase of the clearance may be advisable.

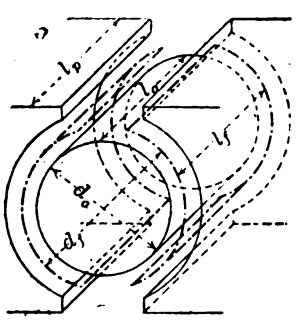

FIG. 46.

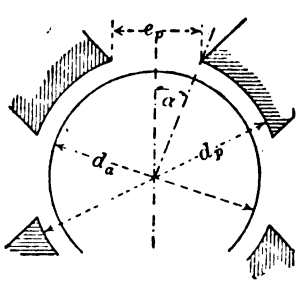

FIG. 47.

(c) *Polar Embrace.*—The dimensions of the magnetic field having thus been determined, half the pole-space angle, α (Fig. 47), can be found from the trigonometrical equation:

$$\sin \alpha = \frac{e_p}{d_p} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (105)$$

e_p = pole distance, in inches, from formula (103);
d_p = diameter of pole-pieces, in inches, from formula (104).

The ratio of polar embrace, or the percentage of polar arc, then is

$$\beta = \frac{90\text{deg.} - \alpha \times P}{90\text{deg.}} \quad . \quad . \quad . \quad . \quad (106)$$

in which α = half pole-space angle from (105);
P = number of pairs of magnet poles.

From (106) follows, by transposition:

$$\alpha = \frac{90 \times (1 - \beta)}{P} \quad . \quad . \quad . \quad . \quad (107)$$

from which the pole-space angle, α, can be calculated in the case that the ratio of embrace, β, of the pole-pieces is given.

35. *Relative Efficiency of Magnetic Field.*—The useful flux of the dynamo being found from formula (91), the number of lines of force per watt of output, at unit conductor velocity, will be a measure for the magnetic qualities of the machine, and may be regarded as the relative efficiency of the magnetic field.

The field efficiency for any dynamo can accordingly be obtained from the equation—

$$\zeta = \frac{\Phi}{E \times C} \times S = \frac{\Phi}{W} \times S \quad . \quad . \quad (108)$$

where ζ = relative efficiency of magnetic field, in webers per watt of output at a conductor velocity of 1ft. per second;
Φ = useful flux of dynamo, from formula (91) or (92);
E = total E M.F. to be generated in machine, in volts;
C = total current to be generated in machine, in amperes;
W = E × C = total output of machine in watts;
S = conductor velocity, in feet per second.

The numerical value of this constant, ζ, varies between 4,000 and 40,000 lines of force per watt at 1ft. per second, according to the size of the machine, the lower figure corresponding to the highest field efficiency; and for outputs from ¼ kilowatt to 2,000 kilowatts, for bipolar and for multipolar fields respectively, ranges as per Table XLIX., which is averaged from a great number of modern dynamos of all types of field magnets.

TABLE XLIX.—FIELD EFFICIENCY FOR VARIOUS SIZES OF DYNAMOS.

Capacity in kilowatts.	Value of ζ, in webers per watt, at unit conductor velocity.	
	Bipolar fields.	Multipolar fields.
Up to ·25	15,000 to 40,000	—
·25 to 1	10,000 to 20,000	—
1 to 10	8,000 to 15,000	10,000 to 20,000
10 to 50	7,000 to 12,000	8,000 to 15,000
50 to 100	6,000 to 10,000	7,000 to 12,000
100 to 500	5,000 to 7,500	6,000 to 10,000
500 to 1,000	—	5,000 to 7,500
1,000 to 2,000	—	4,000 to 6,000

For a newly-designed machine, the value ζ obtained by means of formula (108) will be within the limits given in this table, provided the armature has been calculated in accordance with the rules and tables furnished in the respective chapters of Part I.

As from Table XLIX. follows the self-evident fact that the magnetic fields of large dynamos are more efficient than those of small ones, a curve was plotted in order to

Digitized by Google

examine the rate of this increase. For this purpose the useful fluxes of all the dynamos considered were reduced to the basis of a conductor velocity of 50ft. per second, when the heavy curve, Fig. 48, was obtained by averaging the values of the flux thus found.

From this curve a law can be deduced for the increase of the field efficiency with increasing size. In Table L., from the average useful flux for 50ft. conductor velocity, as plotted in Fig. 48, the specific flux per kilowatt has been calculated, showing the rate of increase of the field efficiency.

By the law of inverse proportionality between useful flux and conductor velocity, the remaining curves for 25, 30, 40, 60, 75, and 100 feet per second respectively were then drawn in Fig. 48.

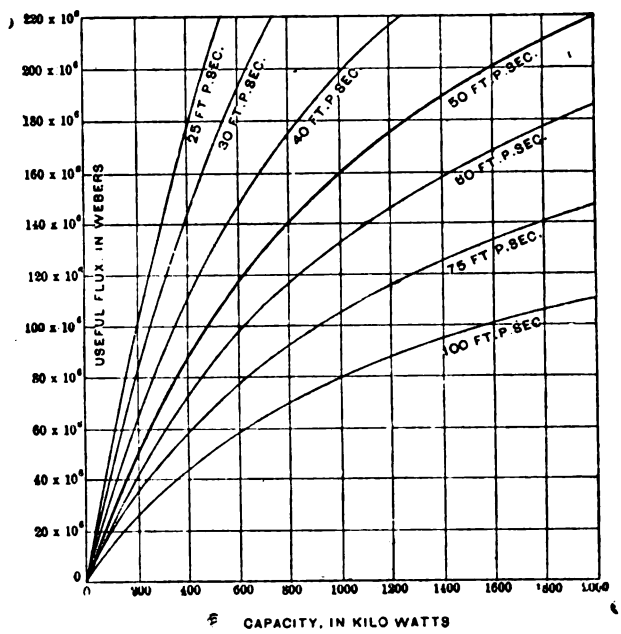

FIG. 48.

Tabulating all the values thus received, we obtain Table LI., which gives average values of the useful flux for various conductor velocities.

(To be continued.)

LIGHTING AND POWER TRANSMISSION BY MEANS OF DIPHASE GENERATORS.

A paper referring to the transmission of power and lighting by means of polyphase currents at the works of Messrs. Weyher and Richemond was presented by M. P. Boucherot to a meeting of the Société Internationale des Electriciens on December 5. After having made investigations, this firm decided to lay down in its works at Pantin a two-phase plant. Among the reasons adduced by the author for the adoption of this system may be mentioned that diphase generators have a higher efficiency than simple alternators, that these motors are more easily started, and that this type of machine is better adapted for the simultaneous distribution of power and light. The Pantin works cover a surface of some 25,000 square metres, and comprise groups of buildings. The old steam-engines of 50, 80, and 120 h.p. have been replaced by a single 400-h.p. horizontal engine running at 60 revolutions, the economical speed of which corresponds to 200 h.p. This engine drives by belting and countershaft a direct-current dynamo which serves as exciter, one three-phase alternator for testing purposes, and three diphase alternators. The countershaft can, in case of necessity, be driven by a 150-h.p. vertical engine in an adjoining room. Each diphase alternator gives 88 kilowatts at 400 revolutions; they are of the eight-pole type, and have a frequency of 40 periods per second. The field coils are fixed and the armature is formed by a drum winding. The author mentions, by the way, that at present flywheel alternators would perferably be chosen. The distributing board carries on the right the alternator switches, and on the left the feeder or line switches. The circuit of one phase is arranged on the upper. part of the board, and that for the other phase on the lower part. On the central portion of the board is placed the measuring and synchronising apparatus.

A comparison of the alternators with direct-current generators gives the following results: cost price 15 per cent. less, efficiency similar, and weak armature reaction. As regards efficiency, the author stated that at full load it was 91 per cent., at half load 87·2 per cent., and at one-tenth load 60 per cent. The distribution of the current is effected by means of eight cables, having a section of 75 square millimetres, carried in the different buildings. Diphase motors are superior to those of the direct-current type. The motors used in the works are of two kinds; in one type the armature is formed of parallel bars of copper connected at their extremity; in the other, the extremities of the armature are connected to rings on the shaft. External rubbing contacts allow of shunting variable resistances. In the first motors, and to avoid too great intensity on starting, the properties are utilised of a self-induction coil and its mutual induction properties. The installation comprises 17 motors of a total of 190 kilowatts; those of 22 kilowatts have a commercial efficiency of 94 per cent., and those of 1·1 kilowatts of 74 per cent. The efficiency of all the motors is 89·8 per cent.; with the loss on the line (4 per cent. and various losses, a total efficiency of 78·5 is obtained on full load. The lighting of the works is accomplished by means of 60 arc and 600 incandescent lamps. M. Boucherot says that if the luminous efficiency of alternating-current arc lamps has been estimated to be inferior to that of direct-current arc lamps, the fact is due to inexact comparisons. The self-induction coils used instead of rheostats allow of a large economy being obtained.

TRANSMISSION OF ELECTRICAL ENERGY FROM THE COALFIELDS.

The scheme advanced by Mr. B. H. Thwaite and Mr. Swinburne for the production at and transmission from central stations in the coalfields of electrical energy for use in the Metropolis and elsewhere is discussed by the former gentleman in the December number of the *Nineteenth Century*. The principle, as may be remembered, is stated briefly by the author as follows:

The project is to supply electric power generated in central stations built in the centre of our coalfields to our great industrial centres, and to the Metropolis itself. The power station for serving the Metropolis would be erected on the Derbyshire coalfield; an auxiliary station to serve the Midland counties would be erected in the Staffordshire coalfield. The electrical trunk lines would serve the larger towns *en route*, including Derby, Nottingham, Birmingham, Leicester, Northampton, and Bedford. Distributing, transforming, and storage stations could be erected near the Metropolis. The different metropolitan and suburban electric light stations could be supplied with energy for general distribution. Electric railways and other power stations could also be supplied. Large power consumers could be supplied with power direct. Each vestry not already supplied with an electric generating plant could be invited to put down a distributing system and a receiving station. The electric energy could be sold to the different distributing companies at such a price as to enable the power to be supplied to the light and power consumer at an economic and attractive figure, or at a little over 1d. per kilowatt-hour. The industrial centres of Lancashire, Yorkshire, and Cheshire would be supplied with electric energy generated in two coalfield stations, respectively near Wigan and Barnsley. The cost of power to the small factory owner need not exceed £5 per 3,000 working hours of one actual horse-power of energy. In the Metropolis, this energy by the present system will cost between £9 and £12.

Digitized by Google

The centralisation of the plant in the coalfields permits the recovery of all the valuable chemical constituents from the coal, which are not recoverable by the small steam-power systems in use. One of these constituents—sulphate of ammonia—is of proved value as a manurial agent, and if this value were recovered from the coal raised from English pits, there would be no necessity to ransack the fields of Chili and Peru for nitrates. The method of transforming the fuel into power could be effected in such a perfect manner as to convert, as far as practicable, all the available heat into work, and produce such an efficiency as will be understood by the ratio of 0·75lb. of combustible to one actual or available horse-power of energy for the period of one hour. The average consumption by existing steam plants cannot be taken as less than 5lb. of fuel for the same actual power during the same time. In the transmission of this electric energy to the Midlands and the Metropolis there will be a loss of, say, 33 per cent.; so that the 0·75lb. will be increased to 1lb. of combustible per actual horse-power per hour.

The cost of the electric transmission cable and wayleaves, divided, as it would be, with the Midland consumers, would not fall heavily in the metropolitan area. For the transmission of 10,000 h.p. three bare conductors for positive and three for negative currents would be used, equipped with oil insulators. Lightning arresters would be arranged where the cables are overhead. The pressure of the current (30,000 volts) would be transformed down to 2,000 volts at the Midland and metropolitan receiving stations, for the convenience of the local metropolitan companies, who can transform the pressure at their own stations down to their normal working and distributing one. The distribution of the electric energy to the various Greater London electric supply companies, at a price of 2½d. per kilowatt or electrical horse-power, would permit them to sell the current to their consumers for 3d. to 4d. per kilowatt, instead of 7d. to 8d. charged by the Metropolitan Company for this equivalent energy.

THE COMMERCIAL POSSIBILITIES OF ACCUMULATORS.

We give below a report of the discussion on the paper read last week on the above subject by Mr. Alfred H. Gibbings before the Northern Society of Electrical Engineers. The paper itself was printed in our last issue.

Mr. Manville congratulated the author on his excellent paper. It had given him pleasure to hear it read, since it referred to a ubject of great interest; and he had had the honour of escorting Mr. Gibbings and his committee over the only tramway system worked on the principle advocated by Mr. Gibbings in the United Kingdom. He had for a long time endeavoured to persuade various local authorities to put up destructor plants in connection with central lighting stations. As long ago as 1892 he placed a complete scheme of that nature before the Vestry of Shoreditch, who adopted the report, but so far had not carried it out. Since that time another important local authority whom he was advising had resolved to erect such plant, and he was at present preparing the plans and specifications for the carrying out of the work. The scheme was almost directly similar to that referred to in the paper, since it provided not only for the erection of a large electric generating station in combination with a dust destructor for electric lighting purposes, but the generating station was to be so arranged that the current produced by it might be utilised for supplying the tramways. He could not agree with Mr. Gibbings as to the evils he stated would result from the use of boilers in a destructor separate from the remainder of the boilers required to make up the full maximum load required by the station; for in his opinion there was no necessity for any boilers to be used, however large the load of the station, within wide limits, excepting those through which the hot gases from the destructor were passing, and in the scheme referred to he was arranging for the erection of four boilers, each capable of evaporating water for 250 h.p., or a total of 1,000 h.p. Each boiler was arranged with two large destructor cells, one on each side of it, and the flues from the destructor cells were so arranged that the gases would pass underneath the tubes of the boilers immediately over the fire-bars. Then, as at heavy load times the gases from the destructor would be quite inadequate to raise the total amount of steam required, an extra amount of steam would be generated in the boilers by the addition of coal burnt in the fire-grate of the boiler. Thus, under these conditions it would be seen that whilst all the gases from the destructor were used for the steam production to their fullest extent, the boilers could always be worked up to their full power by the burning of so much coal as would make up the difference. The fronts of the boilers and the fronts of the two furnaces accompanying them were so arranged on the same level that they could all be attended to by the same body of stokers. He would not, however, dwell on the destructor portion of the question raised in the paper, for in the main he was in hearty accord with the author on the subject. He only regretted, however, that he had taken for example a slow-combustion destructor, such as that used by Mr. Jones at Ealing, as a typical furnace from which to generate steam. In such a furnace but a tithe of the power that might be realised was obtained, and he had little hesitation in expressing the opinion that with the quantity of refuse to be disposed of in Hull, in place of 45 h.p. Mr. Gibbings might rely upon attaining 120 effective horse-power on the average. He joined issue with the author as to the economical use of what he might term locomotive accumulators for running tramway cars. He was actually running the only system of locomotive accumulator traction in use in this country. Experience in such a matter was worth a deal of theory, and he could only tell them that with all the care that was taken in running that system, with all the economy that was practised, and with all the facilities at his disposal for inducing economical working, they had never yet been able to even make ends meet, although receiving very high receipts per car mile. If there was anything unsatisfactory in tramcar running, it was the use of accumulators carried in tramcars themselves. The cost of running a tramway system in that manner under most circumstances was simply prohibitive. It was not the cost of the depreciation of the accumulator plates themselves. They had found that accumulator plates did not cost them more than 1¾d. per car mile, whereas their total cost of running exceeded 9d. per car mile; and if the expenditure directly due to the use of accumulators were eliminated from the system—that is to say, if the tramcars were run directly off conductors, overhead or underground—the cost would barely exceed 4½d. per car mile. Thus, if they added the cost of the renewal of the accumulator plates, 1¾d., to this 4½d., they got a total cost of 6¼d., and there still remained the large balance between this 6¼d. and, say, 9¼d., the actual cost of running; and this 3d. was absorbed in the extra cost of labour in handling the accumulators, cleaning them out, and so forth, and the extra depreciation of the car bodies due to the fumes from the accumulators, which therefore cost a great deal more to keep in repair than in a direct system. It must therefore be obvious to them that if they had their accumulator plates costing actually nothing in themselves, the cost of handling them and making good the damage they did would prohibitively raise the cost above that of other systems, and from these figures they would get a good idea of the insignificance of the fuel question as compared with the other question. They found, as a matter of fact, that they used as nearly as might be a Board of Trade unit produced in the generating station for every car mile run; and this Board of Trade unit did not cost more than 1·2d. to produce, and therefore the energy used cost less than half the extra expenses in handling the accumulators and repairing the cars. This statement would clearly show them that they could hardly hope for satisfactory results from accumulators carried in the tramcars themselves, but he did not wish them to think that he was opposed to the use of accumulators in connection with a tramway system. On the contrary, he thought they would become an integral part of every electric tramway system, but not carried in the tramcars themselves, but used in the station, in which position they would last very well, and the heavy extra expense of charging and handling, and the repairing of the car bodies, would disappear. There would also be the advantage of reducing the size of engines and dynamos so that they would be working at their most economical load all day long, the accumulators making up those big peaks in the loads that in big tramway systems occurred for a few minutes only at a time; and the whole generating system would be worked on a more satisfactory basis than heretofore. Such a system as this had been erected by Messrs. Mather and Platt in the Isle of Man. As regarded the combination of a tramway station with an electric light station, so as to place upon the latter that day load which would produce the decreased cost of current pointed out by Mr. Gibbings, surely those stationary accumulators would be at least as applicable for that purpose as the locomotive accumulators. In connection with the local authority he had before mentioned, he had received instructions to lay out the electric lighting station in such a manner that the current it produced might be sold to the tramway company during 21 out of the 24 hours. It would be necessary for the tramway company to have a set of accumulators at their generating station large enough to run the whole of the tramway system during the time of heavy load in the electric light station, but during the whole of the day and greater portion of the night the output of the electric light station would be available for directly running the tramways and charging accumulators. The generating plant of the tramway company would then consist of two or three motor generators transforming the current supplied from the electric lighting station to one suitable for running the tramway. One or more of those motor generators would be used during the daytime for directly supplying current to the tramway conductors, and the other for charging the battery of accumulators, and when the time of day arrived when the lighting station must cut off its supply of current to the tramway station, then the accumulators would be used for running the whole system. In this way he thought the heavy day load might be given to the central lighting station, which would achieve the author's results, and at the same time the tramway system might be run as efficiently as would be possible under any circumstances. Mr. Gibbings laid stress on the fact that a low-tension system could be more advantageously employed in the central lighting station if power was to be provided for the

Digitized by Google

running of the tramways. In this point also the speaker could not agree with him, and he thought all of them knew that an alternating-current motor, with continuous-current generator attached, would make an almost ideal motor generator when running in conjunction with accumulators, from which the fields of the alternating-current motor might so easily be magnetised, and he therefore maintained that an alternating system of supply would be equally applicable with a continuous system for use in this system.

Mr. Ferranti remarked that he had listened with great interest to the paper, and more especially to that part of it which referred to the combined use of central supply stations for doing the ordinary lighting and charging of batteries for power purposes. The picture which Mr. Gibbings had drawn of the great advantages which might result from such an arrangement, made one feel quite pleased with the great economic possibilities in that direction; but, on the other hand, they had just heard that Mr. Manville had found it practically impossible to make ends meet upon a complete system of electric traction by storage, and no matter how cheaply the current might be produced by the method which the author had described, that it was impossible to do anything very satisfactory upon that plan. Apparently the cost of handling and maintaining the batteries came to nearly as much per car mile as the total cost of working an overhead system, and, therefore, even if Mr. Gibbings got his electricity for nothing for charging the batteries, according to the information which they had had laid before them, it did not look as though it would be of any value. Of course improvements would no doubt be made, but they would have to be very vital ones before that trouble could be got over. Assuming, however, that traction by batteries could be worked commercially if the batteries were charged by current cheaply obtained from the lighting station, they would then have to remember that the plant at the lighting station could only be relied upon for a short number of hours out of the 24, as they would have to leave sufficient margin for the continuous heavy load which was experienced on a few days in the winter of every year. If it were not for that difficulty, no doubt the use of batteries for assisting ordinary supply stations would have been very largely introduced, but practice appeared to have shown that the cheapest thing which they were able to do up till now was to generate the electricity by dynamos as it was required.

Mr. Holroyd Smith observed that some things had been said, and better said, perhaps, than he could say them, by Mr. Ferranti and Mr. Manville, but there was just one point in the early part of the paper—namely, with regard to interested experts. He was afraid that he could not claim to be anything else than an interested expert, and he did not think that Mr. Manville could, and he was afraid that Mr. Ferranti was also one. He might say that that was the first time in the whole of his experience that he had heard a straightforward expression with regard to the cost of working tramcars by means of accumulators. He had seen statements put out to the world which, after falling into the hands of the public, had created an impression not altogether reliable, but Mr. Manville had been very frank in giving figures as to cost per car, etc., confirming—nay, even going beyond the statements he had from time to time made, based on calculations and careful observation of what others had done, for he fully admitted that in battery traction he had been content to profit by the experience of others. He had not wasted time and money on experiments that he felt sure could not have yielded economical results. If accumulators had shown any possibility of their being really better than the other systems, he should have adopted them long ago. But there was one thing which he would like to protest against—namely (the hope had so far been father to the thought), that statements had gone out from interested experts in the electrical world that had been readily taken up by the outside world, and had led tramway directors, town councillors, and others to suppose that batteries about the size of a hat were going to be placed under the seats of a car and drive it all day long. This had got such a firm hold in the public mind that it had been a serious hindrance in the progress of electric traction. The paper must be a very interesting one to the society, because it opened for discussion the debatable question of alternating *versus* direct current for electric lighting stations. It must be interesting to town councillors, giving them difficult questions to digest respecting corporate economy. The speaker then passed on to the 10 points which Mr. Gibbings raised in his paper about the disadvantages of the direct-driving system, taking them *seriatim*. He pointed out that the irregular demands upon the generating plant were not so severe and not so detrimental as the reader of the paper would have them believe, and he ventured to contradict a few of the other so-called disadvantages; especially that the wear and tear with batteries would be less than with direct driving, for when it was known that the weight of the batteries equalled the weight of the car (for example, a three-ton car required three tons of batteries to drive it), then it was obvious that the wear and tear with batteries must be greater, and not less, as stated in the paper. He suggested that Mr. Gibbings ought to have given them a definite tramway, stating the number of cars, hours of working, length of line, etc., and fully worked out his figures showing cost of equipment and working. There would then have been something definite to work with.

Mr. John Hesketh congratulated the author on uttering what they believed to be the cry from all central stations of "give us a day load; we want it, and if we can get it by accumulators let us get it, but by all means let us have a day load." Some people say "at whatever cost." He thought, taken on that view, that the scheme proposed by Mr. Gibbings was excellent, but taking other circumstances into account he was afraid he could not agree with him. He had had the pleasure of seeing one of the principal lines on the Continent worked on the accumulator system, and he at the time wondered how it was that with accumulators of the excellent type which they had, and with the skilled staff and every possible modern convenience, they should still make a loss. But he did not wonder long, for when he got to the station he found one large group of men attending to batteries, another group attending to repairs, and still another attending to cars; altogether, he should say there were about 100 men in the station at that time charging and attending to batteries, etc., for 20 cars. One had not to look far for additional expense, and he therefore did not agree that the running expenses in connection with the accumulator traction were in any way on the same lines as the direct system. Mr. Smith, he believed, asked for some figures in reference to comparative capital costs, and he was pleased to be able to give these. He had got out schemes for running a line on the overhead, conduit, and accumulator systems, based on the same footing, and had found that the accumulator plant cost £5,000 more in capital outlay than the other two, and he therefore thought that the point raised by the author was scarcely borne out.

Mr. A. Lester-Taylor stated, with regard to the Board of Trade regulations and fire office requirements referred to in the paper as being very stringent, that in New York they were practically prohibited from using current for traction purposes in connection with other systems, or rather that no systems might be supplied from these trolley wires.

Mr. Gibbings, in reply, stated that the system which he had set forth and advocated in his paper was simply that which had appeared to him to be the most advantageous to the town of Hull—that was to say, that he had found the conditions in Hull peculiarly suited to that particular kind of traction on account of the level roads and the situation of the central electric lighting station. He did not mean to say that very much profit would be likely to accrue to the tramway enterprise at the present time, but matters were certainly progressing in the direction of the improvement of accumulators. The great advantage which would arise would, however, be from the electric lighting enterprise, because the price could be so reduced that there would be many more people who would be induced to adopt the electric light. Of course they had to decide every case on its own merits. He might mention that Mr. Manville misunderstood his remarks with regard to separate boilers. He did not mean different sets of boilers would have to be employed at the destructor station for the destruction of refuse and generating electrical energy respectively, but the boilers at the destructor station were distinct from those at the electric light station. With reference to the Birmingham electric tramway, this was the only instance in this country of accumulator traction on a large scale, and they had therefore no other place with which a comparison could be made. In reply to Mr. Ferranti, Mr. Gibbings said he had already stated in the paper that his remarks were rather in the abstract than in the concrete, and therefore the possibilities set forth in the paper would of course only hold good where conditions and circumstances were favourable. With regard to the remarks of Mr. Holroyd Smith, he had not meant the observations which he had made concerning electrical experts to be taken in any disparaging sense. Of course, there was no reason why experts should not be given full credit for their own recommendations when lectric tramcars were dealt with as a single and independent concern. With regard to giving figures of an ideal example of such a combination, it had not been his intention in this paper to go into complete details as to total capital expenditure, interest, or depreciation, but simply to give a few suggestions on the subject. To Mr. Hesketh's remarks as to the line which he saw on the Continent, while they did not have much bearing upon the combination suggested in the paper, he would point out that Mr. Hesketh's observations were antithetical to the Rev. Laurence Sterne's, inasmuch as this was one of those things which they did not manage better in France than at Birmingham. He had no further remarks to make upon observations that had been made that evening, but if this paper would lead to further enterprise and experiment, either in the direction in which Mr. Manville or himself had pointed out, he would be amply rewarded. He did not want them to take that paper as a definite scheme which he advocated in its entirety, or as coming from an expert on the subject, but, as before stated, merely one with suggestions and possibilities thrown out, and which if acted upon under fair conditions he would look forward to with no misgiving as to the result.

Mr. Fawcus, the chairman, proposed, and the motion was carried, a vote of thanks to Mr. Gibbings for his paper. He thought that the matter which the author had brought before them was one on which there was a great difference of opinion, but one which was certainly worthy of consideration, especially with a view to increasing the day loads of central stations.

Telephony in Germany.—Telephonic communication has been established between Berlin and Frankfort-on-the-Maine, and also between Strasburg, Kölmar, and Mulhouse.—Telephonic communication has been established between Berlin, Elbing, Tilsit, and Memel.—A telephonic exchange has been opened at Nienburg, on the Weser, with connections with Hanover, Bremen, and Bremerhaven.—The subscribers to the telephone exchanges at Lübeck and Travemünde have been admitted to communication with Berlin and its suburbs.

TRANSFORMER-CHAMBERS IN THE METROPOLIS.

ENQUIRY BEFORE THE BOARD OF TRADE.

In our issue of the 7th inst. reference was made to a forthcoming enquiry at the Board of Trade as to the position of transformer-chambers in public streets. That investigation, which is really an appeal to the Board of Trade, was commenced on Thursday of last week, Sir Courtenay Boyle being supported by Major Cardew, electrical adviser to the Department, and by Mr. F. G. S. Hopwood, of the Railway Department.

The appeal was of the London and Brush Provincial Electric Lighting Company in regard to objections advanced by the London County Council and the Wandsworth District Board of Works to the construction of transformer-chambers under the streets. The appeal is made under the County of London (North) Electric Lighting Order, 1892, and the Wandsworth Electric Lighting Order, 1892. It may be as well to first take the contentions of the London County Council, which were as follow :

Case of the London County Council.

(1) That the transformer-chambers proposed to be used by the company should not be allowed to be constructed under the streets or footways unless it can be shown that in any particular case it is indispensable to place one there.

(2) That such transformer-chambers are not necessary to the carrying on of the company's business.

(3) That such transformer-chambers would be detrimental to the use of pipes, wires, and sewers in the streets, and will be serious obstructions to such pipes, wires, and sewers, and will in practice, notwithstanding any conditions which may be imposed upon the company, necessarily involve expensive modifications.

(4) That such transformer-chambers would be a source of danger to persons passing along the streets, would greatly increase the number of explosions and accidents, and would be dangerous to workmen and others using them.

(5) That the construction of such transformer-chambers would also interfere with the construction of future street widenings and street improvements.

(6) That the use of such transformer-chambers to the large extent to which their admission as a principle would necessarily lead would be very embarrassing to the public authorities in the exercise of their duties, and could not but involve them in much expense for the purpose of supervision, etc.

(7) That from the experience obtained by accidents which have occurred, and from the difficulty of ventilating such transformer-chambers, and their constant liability to flooding and to percolation from gas, water, etc., and the very explosive character of high-tension currents when not properly ventilated, the construction of such transformer-chambers would be most detrimental.

(8) The Council maintain that the proposed use of the streets is purely one of saving the company expense, and that the company should not be allowed to increase their dividends by utilising the streets instead of acquiring houses, cellars, gardens, or courtyards for the purpose of such transformer-chambers.

Reply of the County of London and Brush Provincial Company.

The reply of the company to the before-mentioned objections is as follows :

(1) In reply to paragraph 2, that the transformer-chambers proposed to be used by them are not only necessary but essential to the carrying on of the company's business.

(2) In reply to paragraph 1, that the construction of such transformer-chambers under the streets and footways is in accordance with the practice heretofore adopted with the approval of the Board of Trade and many local authorities, and is the most convenient place, having regard to the safety of the public, the convenience of the customers, and the convenience of access for workmen and others.

(3) In reply to paragraph 3, that such transformer-chambers would in no way be detrimental to the use of pipes, wires, and sewers in streets, or serious obstructions to such pipes, wires, and sewers, or involve expensive modifications. A large number of transformer-chambers—in many cases of far greater dimensions than those proposed to be constructed by the company—have been constructed under footways and streets without detriment to the use of pipes, wires, and sewers, or any serious obstruction to the latter, and any modifications of existing pipes, wires, and sewers required have been carried out by the undertakers under the provisional order in accordance with the terms thereof. The Council are not owners of pipes or wires, or of any sewers but the main sewers, and there is no ground for the suggestion that the transformer-chambers will either interfere with the use or be a serious obstruction to such main sewers.

(4) In reply to paragraph 4, the company say that the transformer-chambers, wherever placed, are no source of danger to the public, provided reasonable precautions are taken in constructing the chambers and connecting the machinery and mains, and that if supplied with a grating at the top as proposed by the company the proposed transformer-chambers will in no way be a source of danger to persons passing along the streets, or to workmen and others using them.

(5) In paragraph 5 the Council say that such transformer-chambers would interfere with the construction of future street widenings and street improvements. The company state that their mains and transformer-chambers will not interfere with any such improvements, and, moreover, that the exercise of the powers given to the company by provisional order should not be interfered with simply on the suggestion that at some future date it may become desirable to widen or improve any particular street for reasons which do not at present exist.

(6) The Council, in paragraph 6, say that the use of such chambers to the large extent to which their admission as a principle would necessarily lead would be very embarrassing to the public authorities, and involve them in much expense for the purpose of supervision. The company would point out that the principle of transformer-chambers is no new one, but has already been accepted, and that in reference to the exercise of their duties by the Council, the company will become a large ratepayer.

(7) In reply to paragraph 7, the company claim that there is no difficulty in ventilating transformer-chambers ; that their construction as proposed by this company shows complete ventilation and no liability to flooding or to percolation from gas and water, and that they will be in no wise detrimental.

(8) In reply to paragraph 8, the company maintain that the construction of the chambers under the footway and streets is not merely a question of economy. (*a*) They point out that if they are driven to the acquisition of private property they will probably purchase the right to use cellars that extend under the pavement and into the streets to which the Council object ; (*b*) that the transformer-chambers are proposed to be placed under the footways of the streets because of the danger that would occur in the efficient lighting of the district in the possible event of the premises under which the transformer-chambers might be placed being burned down, with possible destruction of the ventilating arrangements of the transformer-chambers, of the means of access to the transformer-chambers, and of the connection between the mains and the machinery within the transformer-chamber, whereby a large district might be placed in darkness by causes entirely outside the company's operations, and over which they would have no control whatever.

(9) The company would also call attention to the restrictive clauses in their provisional orders as to the maximum price chargeable, and as to the revision of such price, and also to the purchase clauses in favour of the local authority, and say that no good reason is or can be shown by the Council for putting upon the company the additional expense of the purchase of a large number of bits of property in different parts of their districts merely to prevent the proposed small users by them of the subsoil of the pavements and streets. The company suggest that their transformer-chambers are in no way dangerous to public safety, and point out that if the Council are successful in their contention, it could in some localities prohibit the company from carrying on its operations, because it is not possible to find any space other than space under the public footways for the construction of transformer chambers.

(10) The company are prepared to take the necessary precautions to make the transformer-chambers absolutely safe, and from time to time to take such further precautions as experience may show to be necessary, and would point out that notwithstanding the very large extent to which electric mains and transformer-chambers have been laid under the streets and footways within the Metropolis and in many large and populous centres during the last four years, there has been no fatal accident or serious injury done to any human being or any appreciable damage to property, and claim that no industry can show a record so free from accident as is shown by that of the supply of electricity from central stations in populous places.

Opening of the Enquiry.

The enquiry, as already mentioned, was opened on Thursday of last week. Mr. Bassett Hopkins represented the London County Council and Mr. Earls the Wandsworth District Board of Works. For the County of London and Brush Provincial Company Mr. C. A. Cripps appeared, and for the House-to-House Company Mr. Scott, representing Mr. Germaine.

Mr. Bassett Hopkins, in opening the case for the County Council, stated their objections. He thought the convenience and profit of the company should not be allowed to prevail over the safety of the public. Electric lighting was still in its early youth, and they had not enough experience of the various systems of supply to justify them in coming to any final conclusion. He was advised that it was scarcely possible to keep gas and water out of the chambers, and under the circumstances it was a very serious matter as affecting the public safety.

Mr. Binnie, chief engineer of the County Council, said he considered transformer-chambers objectionable on the ground of the amount of area occupied, the possibility of explosions occurring through accumulations of gas in the chambers, the obstruction caused when inspection took place, and the probability of water finding its way into the chambers.

Cross-examined by **Mr. Cripps**, he stated that he objected to the proposed system of ventilation as shown on the plan put in. He did not think the air would circulate. They could not properly ventilate a vertical pit except by using mechanical machinery or running up a ventilating shaft at the side of the house. The company had not the power to do either of these.

Dr. John Hopkinson gave evidence as to the possibility of explosion. The larger the space the more serious would be the explosion. He supported Mr. Binnie's view with regard to ventilation. At Manchester the Corporation had no transformer-chambers under the streets, but hired cellars. He did not think

Digitized by Google

transformer-chambers were necessary. They could use a different system to the high tension, and it would be as economical.

In answer to **Mr. Cripps**, **Dr. Hopkinson** said he did not think the provisions proposed by the company would ensure a proper diffusion of accumulated gas. He had no experience of a chamber so large as the one proposed.

Mr. James Enright, examined by **Mr. Bassett Hopkins**, considered that transformer-chambers under the pavements were dangerous, owing to the possible accumulation of gas. He believed in the possibility of electrolysis, and regarded the transformer-chambers as unnecessary in the streets.

Mr. Gunyon, assistant engineer to the London County Council, and **Sir Benjamin Baker** having given evidence, **Mr. Earls** spoke on behalf of the Wandsworth District Board of Works, being supported by **Prof. Henry Robinson**. The Court then adjourned until yesterday.

THURSDAY.

Mr. Radford, who was called by **Mr. Earls** at the resumption of the enquiry yesterday morning, stated that he was engineer to the Putney District Board of Works. He was of opinion that the transformer-chambers would interfere with the Board, and also with private owners in regard to gas and water mains. There would be no difficulty in the company obtaining private land for the purpose in question.

Cross-examined by **Mr. Cripps**, the **Witness** admitted that so far every public company had been allowed to take up what room they desired under the streets.

The **Witness**, replying to **Sir Courtenay Boyle**, said that the Board of Works only objected to the transformer-chambers being built in the road and streets because of the space occupied.

Mr. H. J. Martin, surveyor to the parishes of Tooting and Streatham, who was examined by **Mr. Earls**, objected to the use of the roads and footpaths for the accommodation of transformer-chambers on account of the interference with the sewers and gas and water mains. It was possible in nearly every case for land to be acquired for the chambers.

The evidence of Mr. Martin having closed the case of the London County Council and of the Wandsworth District Board of Works, that of the County of London and Brush Provincial Electric Lighting Company was commenced.

Mr. C. A. Cripps, Q.C., in opening the case, referred to the clause, which had since been adopted as a model clause, settled by Sir George Trevelyan's committee, that a distinction must be made between old works and new, and that had met the difficulty in a satisfactory way. The County Council had tried to upset that model clause which had been maintained by parliamentary committees. Dealing with the taking up of the streets, counsel stated that Parliament had left it to the Board of Trade and local authorities to determine whether the particular work was right or proper. The County Council had brought forward the plea that they had a sort of public property in the streets, and that they were not to be used without payment, and in order to enforce that argument they said that there was too much room in the streets, and that the company wishing to use them ought to pay for it. That was answered by the position of the gas and water companies and the railways, which had paid no compensation. It was, moreover, ridiculous in face of the plans and sections put in to say there was no room. The question of system whether it was safe or not was for the Board of Trade to determine. The speaker then went on to discuss Sections 12 and 13 in the Act. The question of safety rested upon the system, and was not a matter which the local authorities were intended or authorised to raise. The company's method of construction was such that the risk of any gas getting in the chambers was reduced to a minimum. He would show them that the system adopted had been introduced by local authorities.

Sir Frederick Bramwell, called by **Mr. Cripps**, said as regarded the safety of the chambers, that the question that had arisen was of exploding gases which might get into the chamber. He believed that a chamber of the small size shown and built as proposed could not under ordinary circumstances admit gas due to leakage. There was only the most remote possibility of the gas entering the chamber. But the chamber was a gastight box, and if that be conceded, all fear of explosion was at an end. Upon, however, the suggestion that it was not a gastight box, he opined that any gas getting in, even in considerable quantities, was incapable of forming an explosive mixture, with the use of the grid cover, because the gas would pass out at the top by reason of its liberty. The witness then referred to some important experiments made by himself and others in 1867 in the Southwark subway, and which showed that with openings the formation of an explosive mixture was out of the question. Whether there was a current of air or not, the gas would pass away through suitable openings. Details of the experiments were contained in the evidence in the Metropolitan Subway Bill, July 30, 1867. He had never heard of an accident in connection with a transformer-chamber.

Cross-examined by **Mr. Bassett Hopkins**, the **Witness** said that, assuming an explosion, other things being equal, it would be more violent in a large than in a small chamber. He did not consider the question of ventilation to be important, but gas drainage was. Coal gas, which might be taken as half the weight of air, would ascend. As a matter of fact, diffusion was slow compared with the power of the gas to rise through the air by liberty. He relied upon the grating at the top of the box to allow the gas out. It was only in 1892 that the County Council tried to drive the electric light mains into subways containing gas and water pipes.

Cross-examined by **Mr. Earls**, the **Witness** was not prepared to say that large quantities of water in the box would cause danger. As an instance of this, he mentioned that the bare copper mains of the Kensington and Knightsbridge Company had been submerged, and the supply of light had still continued.

The **Witness**, replying to **Sir Courtenay Boyle**, observed that there would be greater danger with a transformer in an ordinary cellar than in the chamber.

Re-examined by **Mr. Cripps**, the **Witness** said there would be no difficulty or danger from gas getting into the chambers, which were absolutely safe against this. He could not conceive any difference of temperature in the box which would prevent coal gas from passing into the air.

Prof. Silvanus Thompson did not think the chambers as proposed under the road or footway would result in any danger, and there would be no possibility of gas leaking into them. If, however, gas did enter, the arrangements provided were adequate for public safety. The gas would get away far too soon to cause an explosive mixture, and there would be no explosion. Any difference of temperature between that of the chamber and that of the surrounding air would be in favour of promoting the circulation of air and gas, or a mixture of the two. For the air to be as light as coal gas it would have to be heated more than twice as hot as boiling water. There was not any likelihood of a difference of potential being set up.

Cross-examined by **Mr. Bassett Hopkins**, the **Witness** said that he had seen transformer stations in London and on the Continent. The chambers in the former were large.

Dr. Fleming, who observed that with the types of transformer-chambers proposed there would be no danger to the public safety, thought it would be practically impossible for gas to get in them. He agreed with Sir Frederick Bramwell that even if it did it would immediately pass upwards.

Examined by **Mr. Bassett Hopkins**, the **Witness** said that there would be a circulation of air if the chamber were heated on one side.

Mr. Lawson, engineer and manager to the London and County Brush Company, put in certain plans, and stated that there would be no difficulty in adjusting the position of the transformer-chambers. He had suggested to the surveyors to point out the most suitable places to construct them. Similar chambers had been erected at Dover and Bournemouth.

Mr. Bassett Hopkins then addressed the Court on behalf of the London County Council, and **Mr. Earls** for the Wandsworth District Board of Works, but **Mr. Cripps** had previously stated his intention of not replying.

THE BOARD OF TRADE POLICY.

Sir Courtenay Boyle, who thought it convenient to state what his advice to the Board of Trade would be, had no power to say what was the construction to be placed upon the provisional order. On the occasion of various provisional orders in 1889 the Board of Trade did not contemplate that street boxes would be extended to transformer-chambers. A great deal might be in the words "boxes controlling energy," etc. If in the provisional order street boxes did not include and mean transformer-chambers, then the company had no right there, and neither he nor the Board of Trade were the proper persons to settle the matter. If there was no power given by the order to go under the streets, nothing that the Board of Trade could do could give that power. The Board had no power to give undertakers any rights as regards the streets which were not given in the provisional order. Unless the word "boxes" included transformer-chambers, it seemed to him that procedure must be taken before some tribunal other than the Board of Trade. That being so, he must act as if the word "box" meant a transformer-chamber. He proposed to place his views to the Board of Trade on the assumption that the word "box" included transformer-chambers. The next question was, were the circumstances such as to make it the duty of the Board to say that in the safety of the public no system of supply which included the use of transformer-chambers under the streets should be used. Upon that point his advice to the Board would be based upon the assumption that the case against the transformer-chambers, *per se*, had not been made out. The promoters had undertaken to listen to any representation made by the advisers of the County Council and the Wandsworth District Board of Works in the way of any improvements in the construction of these chambers that were possible or could be suggested; but having regard to the scientific evidence he would advise the Board of Trade, with the chambers made reasonably free from risk, that it was not their duty to veto their use. Then the question arose as to the limits of their use, and in this connection he was much impressed with the argument of Mr. Bassett Hopkins, that there seemed to be no limit to the introduction of transformer-chambers. It appeared to him that that was a question which local authorities were justified in resisting, and which Parliament had not provided for. The action of the Board of Trade would be based upon the assumption that the use of transformer-chambers should be as much as possible curtailed, and that the chambers should be placed where they did not unreasonably interfere with existing wires, pipes and sewers. As to where it was or not interfering, it was impossible for him to give an opinion. The object of the company, he understood, was to place the chambers where they did not cause any such interference. If there was any particular difficulty or any particular transformer-chamber held to be erected where it should not be, then the appeal clause came in, and each case must be considered by the Board of Trade. But they would not propose to veto them *in toto* under the streets. The Board would insist upon the adoption of all safeguards in the construction of the chambers, and they would see that the chambers were placed where they would interfere as little as possible with the property of the user of the subsoil in the streets.

ACCUMULATOR TRACTION.

There is no material fault to be found with the title of the paper lately brought by Mr. Gibbings before the Northern Society of Electrical Engineers, and published in last week's issue of the *Electrical Engineer*. If we understand the author's views aright, however, the substance of his paper contains much that is, in regard to commercial results, somewhat more questionable than the vague generalities implied by its title. There can be no doubt whatever—there has been no doubt of it for some time past, and proof positive is afforded by the Douglas and Laxey Tramway results—that the use of accumulators ought to help enormously in the economical working of electric tramways upon whatever systems they are based, so long as they are maintained at the supply station and not upon the cars.

Mr. Gibbings, however, confines his financial treatment of the subject entirely to the generating plant, and shows a remarkable economy which may be obtained by judicious combination of municipal enterprises. He then assumes the employment of accumulators *upon the cars* as being essential to the success of such a method. It is not easy to follow or agree with the logic of his contention that the power from refuse destructors when applied to the service of a trolley system will only complicate an otherwise simple scheme; though, of course, if the accumulators be stationary, instead of being mounted upon cars, there must be some additional expense for the overhead working gear. But he forgets that the depreciation and cost of labour upon the latter will be far less than upon car accumulators, so that even though, in his own words, the accumulator system can be arranged and worked so as to pay off the entire depreciation of the car accumulators per annum out of lower working costs, there is just as much, if not more, final economy in a slight increase of interest charges owing to a greater capital outlay, coupled with a very marked reduction of accumulator repairs and labour when they are maintained in the central station.

This was pointed out very clearly by Mr. Manville and others in the discussion which followed upon the paper referred to, and which we print on another page. We doubt very greatly whether in any single case the extremely small generating cost per unit which Mr. Gibbings quite fairly claims to be attainable, would allow the setting aside of a sum sufficient for the enormous depreciation and general excessive cost of car accumulators, and yet bring the total working cost below the average rate of an ordinary overhead wire system. The speakers who dilated upon this point when discussing the paper emphasised the cost of attendance and skilled labour for car accumulators, contenting themselves with bringing down the cost of depreciation to something under twopence per car mile. We think that even this figure is a better one than will be maintained in regular work over an extended period; but even assuming that it is sufficiently low for permanent work, this alone is enough to condemn car accumulator traction in its present form. Overhead trolley lines may be, and have

Digitized by Google

been, worked at no greater cost, inclusive of all charges save only management or directorial expenses.

With regard to the entire subject from a general point of view, considerable credit is due to Mr. Gibbings for showing what excellent results in fuel economy and establishment charges may be obtained from a judicious combination of electric lighting and tramway enterprises. It need not, however, be thought that these results are at present theoretical only: they have been reached in several instances where joint working of tramway lines and incandescent or arc lamps is a matter of considerable experience. In this very issue we give particulars of a combined plant of this type employed at Zwickau, in Germany; similar use is made of the electric light station at Gera and Havre also, in each case with entire and complete success.

Usually, the combination is effected with a low-tension system, the difference between pressures of a lighting circuit (one hundred or two hundred volts) and that of a tramway system (five hundred volts) being made up by means of continuous-current transformers. With a five-wire lighting system, the two services might almost be worked direct without any transformation. There is, of course, no difficulty in operating a continuous-current tramway supply from alternating lighting circuits, as Mr. Manville has pointed out: so that whatever type of current supply be chosen for a lighting system—municipal or otherwise—there are no serious obstacles whatever to the successful operation of an electric tramway system conjointly therewith.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

STEALING IDEAS.

SIR,—I find that you turn out to be a true prophet when you stated that the Metropolitan Traction Company, of New York, fraud would result in some Yankees robbing some inventor of his invention and using it for their profit under another name. That electromagnetic system of Washington which you copy this week from your New York namesake is the identical idea that I sent in for the competition. Now it is a surety where the information has been derived. I provisionally protected in England this invention last March after I sent it to them, so they have not lost much time when my seven months allowed by the United States Patent Office expired, and they fancied it safe to do so. I hope to submit to you the original when the patent is accepted at our Patent Office, and then you can judge for yourself. The funny thing of it is, the advantages that I mentioned to them are in my exact words reproduced, and are true in fact. The cost of construction is only half what the overhead system would cost; for example, the magnetic switchboxes can be made at a profit for 10s. 6d. each, the most expensive item being putting the conductors underground and connecting up. The only difference I can see is, I used three or four wheels attached to one bar, and they use two sliding bars; but I do not consider that any improvement.

I should very much like to know what conduit system the Electric Construction Company have in their yard. Is it anything on this principle?—Yours, etc.,

5, Brightside-bank, Sheffield, W. ALDRED.
December 17, 1894.

P.S.—The main point in my invention is the use of electric cells for the purpose of actuating the electromagnet for switching the main current off and on independently of the mains, two storage cells being sufficient for this work.

ELECTRIC POWER IN THE IRON AND STEEL INDUSTRIES.

Some time ago Mr. D. Selby-Bigge contributed a paper on the above subject to the Iron and Steel Institute, showing the advantages accruing through the adoption of electric motors in the iron and steel industries. The paper, which was published in this journal at the time, is discussed in the December number of the *Engineering Magazine*, which says:

While it is probable that there is no one establishment in the United States comparable in size with the Royal and National Arm Factories now employing electricity exclusively as a motive power, it is also probable that electricity has been more generally applied here in the iron and steel industry than abroad. In regard to the application of the electric motor to rolling mills, we are likely to see Mr. Selby-Bigge's prediction verified very shortly, if it has not been already. As this application is unique, it may be well to mention it here. The installation referred to consists of a 30-kilowatt motor connected direct to the rolls, the specifications requiring that it shall be capable of reversing under full load every 10 seconds. No simple shunt-wound motor could meet this requirement, but the contractors feel confident that the Leonard system, upon which they are relying, will enable them to meet every demand. Reference to electrical metal working is conspicuous by its absence in Mr. Selby-Bigge's paper. It is true that this does not properly come under the head of "electricity as a motive power," but it plays such an important part in the iron and steel industry in America, that it must needs be mentioned in this connection. In this country there are being made at this time 2,700,000 welds per annum on steel and iron wire in the utilisation of shorts. On iron pipe for refrigerators, ice machinery, etc., the work done is at the rate of 360,000 welds per annum; on axles, tyres, and hub-bands, 144,000 welds; carriage hardware, 275,000 welds; agricultural machinery (mostly wheels), 720,000 welds; railway construction work (frogs, switches, etc.), 150,000; and on copper and brass wires (from No. ½ to No. 16 A. G.) about 3,780,000 welds. The aggregate power employed, as above, is 4,000 h.p. In addition to this, 200 h.p. is employed in the U.S. navy yards for welding purposes, and 250 h.p. for the production of electrically-welded projectiles used by both army and navy.

Electric travelling cranes have come into such general use as no longer to excite remark, and they have been constructed in sizes far larger than any employed abroad. For instance, the English electrical journals recently described the completion of a 60-ton electric crane at the Seraing works of the John Cockerill Company, Belgium, as probably the largest in the world. There are quite a number larger than this in use in this country, two of which—75 and 150 tons—are at the Watervliet Arsenal. We also have put into successful practice the direct application of the motor to the tool as recommended by Mr. Selby-Bigge. Noteworthy examples of this are found in the universal drilling machines in the Cramps shipyard and in the Southwark Foundry.

In our rolling mills electricity is all but universally used for illuminating purposes, and has also found many applications as a motive power. For instance, in the Homestead mills, the cranes used for handling and transferring ingots as they come from the furnace are operated by electric motors, and at the Edgar Thomson Steelworks the ingots are charged into the soaking pits by the same agency. In the navy yards the following installations have been made: Washington, D.C., Navy Yard, 100 kilowatts for arc lighting and electric crane; Mare Island Navy Yard, 140 kilowatts for arc and incandescent lighting; Norfolk, Va., Navy Yard, 280 kilowatts for arc and incandescent lighting, motor service, and electric welding; and there is at

Digitized by Google

present under contract for the Boston Navy Yard, 120 kilowatts for arc and incandescent lighting, and for League Island Navy Yard, 60 kilowatts for arc and incandescent lighting, making a total for the United States navy yards of 900 kilowatts. In the United States navy the total electricity capacity actually installed in all of the vessels to date is 1,470 kilowatts, chiefly employed in incandescent lighting apparatus, for hoisting ammunition, and for search-lights. One ship, the "New York," has been supplied with an electric launch, and several ships have been equipped with the Fiske electric range finder for ascertaining ranges.

Experiments are, however, being conducted with a view to a much more extensive application of electric power on board ship as a substitute for steam for elevating guns, operating ventilating fans, and last, but not least, for revolving turrets. This latter application is considered the most difficult, and, so far as the Bureau of Ordnance is aware, has not been attempted elsewhere than in the experiments recently tried by them at Philadelphia. Thus while we probably find the application of electricity in the iron and steel industry in the United States nowhere quite so complete as in the instances cited by Mr. Selby-Bigge, we find it making enormous strides in every direction, having made some important conquests here that it has not made abroad.

COMBINED ELECTRIC LIGHT AND POWER STATION.

A central electric light station is now in operation in Zwickau, Saxony, with which is combined the plant for the working of an electric tramway. The local authorities granted a concession for this purpose to the Schuckert Company and to Messrs. Leo Arnoldi, of Mayence, but for the present only one tram line from the Zwickau railway station to Schedewitz, a distance of 2½ miles, is worked by electric cars.

It was considered that to maintain a six-minutes' service on this line nine cars would be required, and that for the extension from Schedewitz to Wilkau, nearly two miles further, a service every 12 minutes with two cars in operation would be sufficient. It was also estimated that 4,000 16-c.p. lamps simultaneously alight would be ample for meeting the requirements of the town, which has a population of 50,000. These points having been borne in mind, it was thought advantageous to combine the generating plant for the two services. This was carried into effect, and the distribution of current for lighting purposes is effected on the three-wire system, and for the operation of the tramway on the two-wire system with overhead trolley and return by the rails. For the former purposes the generators are arranged in parallel, and for the latter two in series.

The boiler-house contains three Cornish boilers, constructed for a working pressure of 125lb., and fitted with Galloway tubes. The engines, three in number, are of the compound horizontal condensing type, and each gives 100 h.p. at a speed of 150 revolutions. Each engine drives two generators by belting. The first pair of dynamos, which are only intended for providing light, is arranged for parallel running, both for the charging of accumulators and for feeding direct into the mains. This disposition has been adopted in the case of the second pair. It is, however, possible to connect these two machines in series so that they form a reserve either for lighting or for traction purposes. The third pair of machines is mainly used for the operation of the tramway, but they can also be connected to the feeder mains for the supply of light. In order to increase the efficiency of the installation, a continuous-current transformer has been laid down. The object of this transformer, of course, is, according as may be required, to bring the excess of lighting current up to the pressure necessary for the working of the tramway, or to reduce the pressure of the surplus tramway current to that of the lighting circuits. The normal output of the generators is 48 kilowatts, the E.M.F. being 250 volts. The battery comprises 136 Tudor cells. The cables are of the Felten and Guilleaume type, lead-covered and iron-armoured, and mostly laid direct in the ground. The tramway, which is 2½ miles long, is worked by nine cars.

LIGHTING A RESIDENTIAL DISTRICT.

The electric lighting of the so-called Thiergarten or Zoological Garden district, which is a residential quarter of Berlin, forms the subject of an article by Mr. Emil Rathenau in the *Elektrotechnische Zeitschrift* of December 6. The Berliner Elektricitätswerke already had a generating station in the Mauerstrasse, which is some 2,000 metres distant from the extreme point of consumption in the Thiergarten quarter. Having powers to supply light in the latter district, it was decided to erect a battery station in the Königin Augustastrasse, from which consumers could be supplied. The distributing system of the Thiergarten district and that of the Mauerstrasse station are connected together. The charging main is an iron-armoured lead-covered cable laid underground. The current for the Thiergarten station is obtained from the omnibus bars in the Mauerstrasse station, where by means of auxiliary dynamos it is brought to the pressure requisite for the charging of the accumulators or for feeding into the Thiergarten network. By means of suitable switching arrangements, the current delivered into the battery station from the Mauerstrasse generating station is either utilised for charging the accumulators during the so-called charging period of working—in which a part of the current is used for supplying during the charging time, late at night and in the day, the small number of lamps alight—or the charging main is directly connected in parallel with the battery discharging mains, and is sent into the distributing network. The latter, of course, occurs at the time of maximum demand. The time of charging can be extended or restricted to a smaller or larger number of hours.

The current from the batteries is led to omnibus bars, and then distributed on the three-wire system. The latter are arranged for a capacity of 11,600 lamps simultaneously alight, when the loss in pressure in the mains reaches about 20 volts per outer conductor. It was estimated that the probable number of lamps installed in the district would be 50,000, and that one-fourth would be simultaneously alight. Experience has confirmed this view of the matter, as at present one year after the commencement of the supply 15,000 lamps are installed, and the installation has only to give current for a maximum of 3,500 lamps. The auxiliary dynamos in the Mauerstrasse station, which are driven by electric motors, give 400 amperes, and when replaced by larger machines furnishing 800 amperes the battery station will be able to supply 9,600 16-c.p. lamps. The accumulators are of the Tudor type, comprising 138 cells. The loss in pressure in the charging main at full load is between 13 and 14 volts. To compensate for this, and to provide the proper pressure at the battery station, the auxiliary dynamos work at 50 volts. The installation has been carried out by the Allgemeine Elektricitäts-Gesellschaft, and is working successfully.

THE SPERRY ELECTRIC TRAMWAY EQUIPMENT.

A forcible reminder of the paper read recently before one of the United States institutions, on "The Use of the Electric Brake in Railway Practice," is afforded by the new catalogue issued by the Sperry Electric Railway Company, of Mason and Belden streets, Cleveland, Ohio. The equipment furnished by the company consists of one motor, the armature shaft of which runs parallel with the rails and midway between the wheels. This motor is elastically supported on suitable springs from the side bars of the truck frame, and rides as easily as the car body itself. Motion is given the axles through bevel pinions and gears, a universal coupling transmitting the armature torque to the pinion shafts.

In the electric brake which has been devised by Mr. Sperry, the braking current is not derived from the central station, but is produced by the power of the moving

Digitized by Google

car. The brake is automatic and does its work without any special act or even the knowledge of the motorman, who simply works a handle. The operations thus automatically performed are: the conversion of the motor into a special dynamo for generating currents at very low speed; the simple cutting off of all connection with the trolley current and applying the brakes. The act of releasing the brake re-establishes the connection with the trolley and reconverts the dynamo into a motor, the same rheostat and contacts being employed to control the motor while running the car and also to control the slight amount of current generated by the transformed dynamo, which is sufficient to brake the train. The simplicity of the arrangement is shown by the fact that only one small wire extra need be run to the controller in addition to the ordinary wiring of the equipment without the electric brake. The braking action is twofold. The rotating armature of the motor, instead of tugging ahead by its momentum, is itself pulling back and more or less powerfully braking the car through the gears by the retarding effort of the magnetism of its field, while generating the braking current. The power required, therefore, to perform this work is taken from energy of the moving car which it is desired to destroy; not only is the car thus retarded, but the electric brakes arrest the motion of the wheels direct with a force that is powerful and under perfect control of the motorman. Two forms of braking magnets are used, one for winding up a brake chain usually employed in connection with the trailer, and another for directly arresting the motion of the axles, one magnet only being used in connection with each axle. These magnets are truck-mounted, and are so supported that their gravity acts to automatically retract them away from the brake face. The brake face is automatically lubricated to a slight degree, receives a high polish, and does not cut or rapidly wear. This type of brake has been in operation on many lines for over a year with complete success.

NIGHT-LIGHT WATCH-STANDS.

Some ingenious watch-stands for bedroom use have been introduced by Messrs. Siemens Bros. and Co., Limited, of 12, Queen Anne's-gate, Westminster, S.W. It will, of course, be understood that the lamps fitted to these stands, types of which are illustrated, are intended to be alight for a minute or two at a time, and only for a few times nightly. In Fig. 1 is shown a cheap form of electric light watch-stand equipped with three D-size Obach dry cells and a 1-c.p. lamp. These dry cells are very suitable for the intermittent lighting of low candle-power incandescent lamps, and, as illustrated, they are fitted in ornamental cases for the purpose in question. Fig. 2 represents a similar type of electric light watchstand, fitted with three batteries, a lamp of 1 c.p., and a flexible cord with a pear-shaped push. A stand of a more ornamental character is shown in Fig. 3, the case being of highly-polished wood with gilt fittings, and equipped similarly to the two preceding watch-stands. By the judicious use of the lamps in the

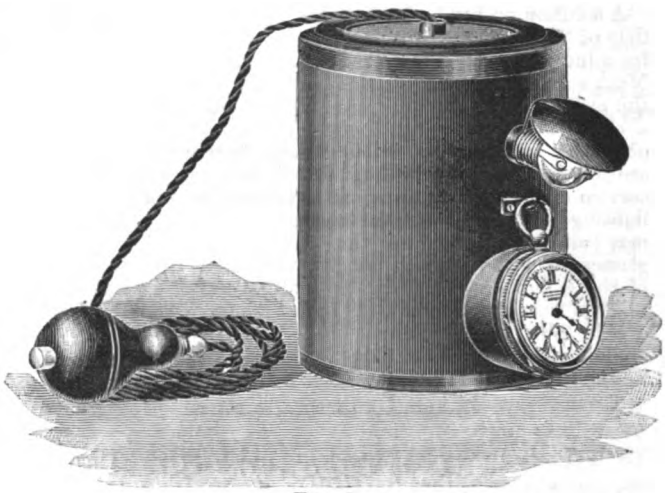

Fig. 1.

manner mentioned, the three cells with which each watch-stand is provided will suffice to light the lamps to the extent of 400

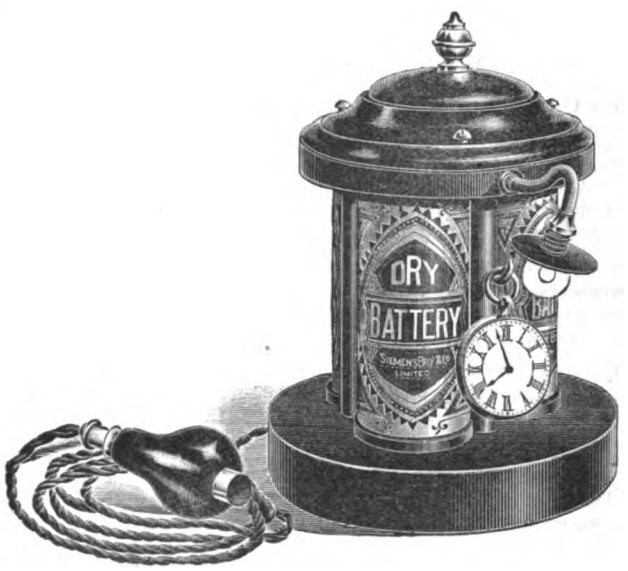

Fig. 2.

times when the lamp is only used two or three times a day. Lamps of higher than 1 c.p. can be obtained by using the A size of Obach cells. Six such cells, connected in series, and placed in a teak box with lid, terminal screws, and handles, weigh about 40lb., and will light a 5-c.p. five-volt lamp. These night-light watch-stands should prove very useful for domestic use, but they must not be made to serve the purpose of reading lamps.

SHADING INCANDESCENT LAMPS.

A solution or kind of paint has been introduced under the title of "Shaydolite," for the purpose of toning down the light from incandescent lamps. Messrs. Griffiths Bros. and Co., of Mack's-road, Bermondsey, S.E., who are placing this liquid on the market, state that they have been conscious of the want of a cheap and easy method of toning down the light, and of obtaining variations of colour for decorative purposes. They are of opinion that "Shaydolite" will be found of great service as a ready means of obtaining effects with electric lighting that are not otherwise procurable, and that there may also be a use for this fluid in colouring the lamp glasses of the Welsbach lamp, as to many people the glare of these lights is very trying. "Shaydolite," which is supplied in stone bottles, is made in most colours, shades of which can be obtained by mixing one with another. The paint is applied either by dipping the bulb into the "Shaydolite," or by the use of a soft brush.

DEWSBURY ELECTRICITY WORKS.

As we mentioned briefly in our last issue, the Dewsbury central electric light station was opened last week. Amongst those present were the Mayor (Alderman Kilburn), Mr. W. H. Preece, C.B. (the engineer of the works), Mr. R. E. Crompton (Messrs. Crompton and Co., London, the makers of the engines, dynamos, etc.), Mr. J. B. Recano (Messrs. Siemens Bros., London, the contractors for the mains), Mr. Mark Scott (the contractor for the buildings), Mr. H. C. Marks (borough surveyor and the designer of the buildings), Mr. J. B. Mitchell (electrical engineer to the Corporation), and Mr. A. Pickersgill (assistant electrical engineer). Messrs. Horsfield, the makers of the three boilers in connection with the works. were also represented.

The **Mayor** said his duty was a very pleasing one, of calling upon Alderman Robinson, the chairman of the Gas and Lighting Committee, to set the works in motion. A speech on electricity was not expected of him—indeed, he knew very little of the subject, but he was pleased to see around gentlemen who were well versed in matters concerning electric lighting installations.

Alderman Robinson said that during latter years the people were not satisfied with the brilliant light from Bray's burners, and it was almost a matter of compulsion to adopt some system of electric lighting. Two electric lighting companies having endeavoured to gain powers to supply electricity in Dewsbury, it became necessary for the Corporation to oppose and early in 1890 there was a conference with the Board of Trade and one of these companies, who were given to understand that the Corporation intended to protect their own interests. On October 29 the Council resolved unanimously to supply electricity, and to apply to the Board of Trade for the necessary powers. On November 17 the two companies sent notice of withdrawal. On July 9. 1891, the Town Council appointed the Gas and Water Committee the Electric Lighting Committee to carry into effect the Dewsbury electric lighting order, and shortly after that body made special visits for information to the Crystal Palace electric lighting exhibition, the stations at Kensington, Knightsbridge, Liverpool, and Preston, and on June 9 Mr. W. H. Preece, one of the most talented specialists in the kingdom, was engaged to prepare plans, specifications, etc , and report and advise generally. The report was considered, and on June 30, 1893, he had a consultation with the General Purposes Committee, and his report, etc., were approved, and tenders asked for. The site of the old gasworks in Bradford-road was decided upon as the central lighting station. Tenders for boilers, engines, dynamos, cables, etc., were accepted. Alderman Robinson gave in detail a description of the works.

Mr. W. H. Preece observed that there were several matters concerning the works that demanded their attention. In the first place, it was important to notice the compactness of the installation. Though the engines took up a very small space, they were of about 500 h.p. Ten years ago it would have been impossible to have provided a station like the present one. They would have required four times the space for the horizontal engines and belting. Another feature well worth noticing and inspecting was the battery-room at one of the engine-houses. The special object of the batteries was to enable them to tide over the night, to provide electricity as well as in the daytime—in fact, to act and serve all the purposes required when it would not pay to keep the machinery going. In the battery-room would be stored sufficient current to light the places necessary, and so save the engine power. They had been up to date with everything, and Dewsbury Corporation possessed electric lighting works on the most improved system, and such as would compare with similar works in any town in the country.

Mr. Crompton said it was in 1881 when his firm came first to Dewsbury and provided the town with electric light for a temporary period. The enemies of the electric light said there were a good many electric lighting installations started and abandoned, but that was not the case. These were only of a temporary character, and it was unfair to class them with installations of a permanent character.

Alderman Robinson, in reply, expressed the hope that the new undertaking would be a triumphant success, and immediately set the first engine in motion. The second engine was set in motion by Alderman Pyrah, and Councillor Archer (vice-chairman of the Gas and Lighting Committee) set the third engine in motion.

LEGAL INTELLIGENCE.

MUIRHEAD AND ANOTHER v. THE COMMERCIAL CABLE COMPANY.

In the Court of Appeal on Tuesday, before the Master of the Rolls and Lord Justices Lopes and Rigby, the appeal of the defendants from the judgment of Mr. Justice Kennedy at the trial of the action without a jury in April last, and reported in our issue of May 4, was decided. The Court allowed the appeal, the Master of the Rolls dissenting.

It will be remembered that the plaintiffs, who are the patentees and proprietors of certain patents for the system of duplicating cables known as the Muirhead duplex system of telegraphy, sued the defendants, a foreign company, incorporated under the laws of the United States of America, and the owners of certain telegraph cables between North America and Ireland, to recover £3,566 for royalties in respect of a part of the year 1891, under a deed dated January 2, 1884, giving the defendants a license to use certain patents of the plaintiffs in consideration of certain yearly payments. The defendants admitted the deed, but alleged that the patents in question had expired at a certain date, and that they were not liable to pay the royalties claimed. It appeared that Messrs. Muirhead took out an English patent in 1876 for duplex telegraphy, and in 1880 they took out a patent in the United States for duplex telegraphy. The English patent expired in 1890, and the defendants contended that the American patent of 1880 was substantially identical with the English patent of 1876, and that the American patent expired at the same date as the English patent, inasmuch as the law of the United States provides that every patent granted for an invention which has been previously patented in a foreign country shall be so limited as to expire at the same time with the foreign patent. They, therefore, contended that the American patent had expired, and that they were not liable to pay the royalties claimed. If, on the other hand, as the plaintiffs contended, the American patent were not substantially identical with the English patent, the American patent would last for 17 years from 1880, and the defendants would, therefore, be liable not only in this action, but also for royalties up to the expiration of the American patent. By means of Muirhead's duplex system of telegraphy two submarine telegraphic messages can be sent along the same cable at the same moment in opposite directions. Formerly, when a message was sent along the cable from, say, England to America, the receiving instrument on the English side as well as that on the American side was affected by the electric current. Muirhead's patents were to render the receiving instrument at the end from which the message was sent unaffected by a message sent from that end, with the result that a message could be sent from the opposite end at the same time. The chief essential was to maintain a perfect balance of electric pressure, and this was done by means of a mechanical contrivance, used at both ends of the cable and known as Muirhead's artificial cable, in combination with certain resistances and other known electrical appliances. At the trial a number of scientific witnesses were called upon both sides as to whether the two patents were substantially identical—that is, whether the two inventions claimed were the same. The learned judge came to the conclusion that the English patent of 1876 did not contain the same combination as was found in the American patent of 1880, and that the latter was a good and novel patent. He accordingly gave judgment for the plaintiffs. The defendants appealed.

Sir Richard Webster, Q.C., and Mr. Moulton, Q.C. (Mr. A. J. Walter with them), appeared for the defendants; Mr. Finlay, Q.C., and Mr. Bousfield, Q.C. (Mr. Pollard with them), appeared for the plaintiffs.

The Court, having taken time to consider, delivered judgment on Tuesday, as already stated, allowing the appeal, the Master of the Rolls dissenting.

The **Master of the Rolls** said that the question in the action related to two patents, one in England and the other in America. If the American patent had not expired the plaintiffs were entitled to recover. The case was tried before Mr. Justice Kennedy, and he (the Master of the Rolls) was prepared to say that he had never read a judgment more accurately written, in which the learned judge went step by step through the case most carefully, and the judgment was so admirably expressed that he was unable now to add anything to it, and he was prepared to adopt it as his own. The learned judge stated the law correctly, and the question was whether the invention patented in America was the same invention as was patented in England. The patent in America was for a combination. It was so in terms, and was so claimed. That combination consisted in the relative position of certain things in it which were to do the work, and the patent was for a combination of those things in that position. Then how could the English invention be the same unless it was for the same combination? The English invention was not claimed as a combination, nor was it used as a combination. Certain of the scientific witnesses stated that the particular placing of the things as described in the American patent was a most useful invention, and that between the time of the English and the American patents the combination was not used because it was not discovered. Therefore, he came to the conclusion that the American patent was not the same as the English patent. He came to the conclusion that Mr. Justice Kennedy was right. But if the matter was left in any doubt, in order to shorten the period of the American patent the whole burden of proof rested on the defendants, and the matter being

Digitized by Google

left in doubt, that burden had not been discharged. In his opinion the appeal should be dismissed.

Lord Justice Rigby read the judgment of Lord Justice Lopes and himself, in the course of which he said that the decision in the case depended upon one point, and one point only—namely, whether or not the United States patent of 1880 came to an end when the English patent of 1876 expired. He did not think that Mr. Justice Kennedy's findings as to the United States law could be impeached, and he agreed with the learned judge that a test of the identity of the patents was whether a structure made according to the foreign patent would infringe the United States patent. He also agreed that the burden of proving the identity of the two inventions lay upon the defendants, and that the principle of introducing into any patent by implication any claim not expressly contained therein ought to be applied with the greatest possible caution. His Lordship then proceeded to consider the construction of the two patents and the evidence relating thereto, and, having elaborately examined the two patents, and having gone through the scientific evidence upon the point, came to the conclusion that the defendants had made out their case affirmatively, and that there was no room for the application of the principle that, where there was a doubt, the doubt should be resolved in favour of the United States patentee. He did not in any way differ upon the law from the learned judge, whose judgment, he agreed, was most admirably expressed, but he did differ from him in the conclusions of fact at which he had arrived.

SHELFER v. THE CITY OF LONDON ELECTRIC LIGHTING COMPANY—MEUX'S BREWERY COMPANY, LIMITED, v. THE SAME

In the Court of Appeal on Tuesday before Lord Halsbury and Lord Justices Lindley and A. L. Smith, an important decision was given in the case of the appeals of the plaintiffs against a judgment of Mr. Justice Kekewich reported in our issue of April 27 last.

The plaintiff in the first action is the tenant, under a lease granted to him in March, 1893, by the plaintiffs in the second action, for a term of 21 years, at a rental of £70 per annum, of a public-house called the Waterman's Arms, situate at Bankside, Southwark. The plaintiffs in the second action are the owners of the public-house. The plaintiff Shelfer by his action claimed an injunction to restrain the defendants from using or working in or upon their premises at Bankside, which adjoin the public-house, any dynamo or other engine or machinery, in such a manner as, by reason of vibration or otherwise, to injure the structure, fixtures, or fittings of the public-house, or to interfere with the enjoyment by the plaintiff of the house, or his use thereof for the purposes of his business, or in any way so as to cause a nuisance to the plaintiff or injury to his house or business. The plaintiff also claimed damages for injury arising from the subsidence, vibration, and noise caused by the works and operations of the defendants, and generally for the alleged wrongful acts of the defendants. The plaintiffs in the second action made a very similar claim. The defendants contended that, in the absence of negligence on their part, they were exempted by their statutory powers from any liability to an action for nuisance, and, moreover, that no actionable nuisance had been proved to exist. It was also urged that the plaintiffs in the second action being reversioners, they had no cause of action in respect of a nuisance which was not necessarily permanent, and might have been removed before the reversion fell into possession. Section 82 of the provisional order (afterwards confirmed by Act of Parliament), under which the defendants derive their authority to carry on their works, provided: "Nothing in this order shall exonerate the undertakers from any indictment, action, or other proceeding for nuisance in the event of any nuisance being caused by them." Mr. Justice Kekewich held, upon the construction of the Acts and the provisional order under which the defendants obtained their powers, that the defendants were not exempted from liability to an action for nuisance. His Lordship further held, upon the evidence, that it had been proved that, by reason of the working of the defendants' engines, injury was caused to the premises in question by vibration and noise, and also, in some degree, structurally. Having regard to the manifest inconvenience which would result to the inhabitants of the district which the defendants supplied with electricity, if their works were stopped, his Lordship did not think fit to grant an injunction. The plaintiff lessee was, however, entitled to enquiries as to the damages caused to him as such lessee by vibration, noise, and structural injury, and to the costs of the action, and there must be judgment to that effect. As regarded the other plaintiffs, their action so far as it claimed an injunction must be dismissed with costs, it being clear upon the authorities that being reversioners they were not entitled to relief by injunction in a case such as the present. They were, however, entitled to an enquiry as to any damage done to the inheritance, but the costs of such an enquiry must be reserved. Both plaintiffs appealed, mainly on the ground that an injunction ought to have been granted. It was said that Lord Cairns's Act did not authorise the substitution of damages for an injunction in such a case as the present.

Mr. Warmington, Q.C., Mr. Badcock, and Mr. Waggett were for the plaintiffs; Mr. Moulton, Q.C., Mr. Renshaw, Q.C., and Mr. W. C. Braithwaite were for the defendants.

Lord Halsbury gave the following judgment on Tuesday morning: The two plaintiffs in this case complain of a nuisance created by the defendants by the vibration of their engines and the annoyance caused by the carrying on of their electric lighting works. Of the result and gravity of the nuisance no serious denial has been made before us. The two plaintiffs are respectively the lessee and reversioner of the house known as the Waterman's Arms. The considerations which arise are applicable to both plaintiffs, except in so far as one is lessee and the other reversioner. I will deal with this question separately. The nuisance being established, it is said, first, that the defendant company are authorised by law to carry on the business, and that they have done all that skill and care can effect to prevent any nuisance; that they are in the same position as a railway company, and they are entitled to do what they have done under the authority of the Legislature. If the analogy were a correct one, I should think the defendants had fallen very far short in the proof that they had done all that was possible to prevent a nuisance. A railway company has a definite line of operation within which it may make its works, and if it does all that can be done to prevent a nuisance in that place, the thing having to be done in that place and the traffic having to be carried on by means of locomotives over the line of railway, the Legislature is taken to have sanctioned that proceeding. No such considerations apply here. There is a difference—the object of the legislation and the results. It is not, however, necessary to deal with this part of the case, and I only mention it to disclaim the notion that I acquiesce in the allegation that it has been here proved that it is essential to the carrying on of the electric lighting business in the district in question that there should be a nuisance created. The main question turns on the Electric Lighting Act, 1882, and the provisional orders which have become Acts of Parliament. It was boldly contended by Mr. Moulton that the provisional order protected the undertaking, and that if a nuisance were necessarily created by the carrying on of the company's undertaking such nuisance was authorised and even imposed as a duty on the undertakers. I think it is only necessary to read the provisional order in connection with the tenth section of the Electric Lighting Act, 1882, to dispose of that argument. The provision in the Act, so far as relates to powers under provisional orders, is in these words: "The undertakers may, subject to and in accordance with the provisions and restrictions of this Act, and of any rules made by the Board of Trade in pursuance of this Act, and of any license, order, or special Act authorising or affecting their undertaking, and for the purpose of supplying electricity, acquire such lands by agreement, construct such works, acquire such licenses for the use of any patented or protected processes, inventions, machinery, apparatus, methods, materials, or other things, enter into such contracts, and generally do all such acts and things as may be necessary and incidental to such supply." And then, in the order relied on for the authority to create the nuisance, come the words: "Nothing in this order shall exonerate the undertakers from any indictment, action, or other proceeding for nuisance in the event of any nuisance being caused by them." The general Act only gives them power subject to the restrictions of their particular order, and the particular order makes them liable for nuisance. I have also come to the conclusion that the powers given by the seventeenth section of the Act, read together with the tenth section, are applicable to the execution of the authorised works; and when one considers how frequently the distinction between the execution of the works and the use of them when executed has been the subject of comment and discussion, I think it must be taken that the language used has been deliberately chosen by the Legislature as pointing to the distinction, now well recognised, between the construction of works and the user of them when constructed. But assuming that there is a nuisance, and that there is no authority justifying it, the question still remains, What is the relief to which the plaintiffs are entitled? But for the provision of Lord Cairns's Act, I suppose no one would have doubted that in the state of facts I have now assumed to exist the plaintiff Shelfer would have been entitled to an injunction to prevent the continuance of the nuisance. Lord Kingsdown, in the House of Lords (Imperial Gaslight and Coke Company *v.* Broadbent), has laid down the principle in words which comprehend such a case as this as follows: "The rule I take to be clearly this: if a plaintiff applies for an injunction to restrain the violation of a common law right, if either the existence of the right or the fact of its violation, he must establish that right at law (and its violation). I apprehend, unless there be something special in the case, he is entitled as of course to an injunction to prevent the recurrence of that violation." But it is said, and truly said, that the law has been altered by Lord Cairns's Act, and the question is, What construction is to be placed upon this enactment. Undoubtedly it conferred upon courts of equity the jurisdiction to award damages which did not exist before. But the question is, Did it mean to interfere with the well-settled principles upon which courts of equity were in the habit of interfering in such cases as the present? It seems to me that the defects in the powers of the equity courts which were sought to be supplied by that statute give ample grounds for the provisions of the statute, without supposing that it meant to revolutionise the principles upon which equitable jurisprudence had been administered up to that time. The language, of course, is general; the discretion given is necessarily wide enough in terms to authorise a judge to award damages where formerly he would have given an injunction. But there is nothing in this case which to my mind can justify the Court in refusing to aid the legal rights established by an injunction preventing the continuance of the nuisance. On the contrary, the effect of such a refusal in a case like the present would necessarily operate to enable a company who could afford it to drive a neighbouring proprietor to sell, whether he would or no, by continuing a nuisance, and simply paying damages for its continuance. But, while I can agree with neither Mr. Warmington

Digitized by Google

nor Mr. Moulton upon the alternative restrictions which each respectively seeks to place upon the statute, I see no trace of any such intended alteration of the principles upon which equity should interfere with an injunction as would be involved in a refusal of an injunction here. And further, I think the question is here covered by authority of which Martin *v.* Price in this court is the last example. For these reasons I think the judgment of Mr. Justice Kekewich should be reversed as far as the refusal of an injunction is concerned, and that an injunction should be granted. The point which I have reserved for treatment in respect of Meux's action depends on their interest in the premises. They are reversioners, and the action by the reversioners can only be justified if the reversion is affected. But how is it possible to contend that the reversion is not affected if the walls of the house are so shaken by the nuisance in question that cracks are developed in the building, which experts consider will increase with the continuance, indeed, to increased sources of vibration, by the erection of larger and more powerful engines? I think there is ample evidence here of serious and permanent injury to the reversion by the continuance of the nuisance, and that, therefore, the same judgment ought to be given in respect of the reversion. As the reversioners and the leaseholder represent the entire interest, it will be proper, in respect of the assessment of damages for past injuries, to see that the defendants are not made liable for the same damages twice over. The result is that the appeal succeeds so far as the injunction is connected, and that, therefore, the judgment of Mr. Justice Kekewich should be reversed in that respect, and the defendants should pay the costs.

Lords Justices Lindley and **A. L. Smith** gave written judgments concurring.—*The Times.*

GR ST AND TURNER v. FOWLER-WARING CABLE COMPANY, LIMITED.

This case, which has been heard before the Lord Chief Justice and a special jury, was an action by a firm of electrical engineers to recover damages for breach of a contract to supply them with a cable fit for work similar to that of a telephonic exchange. The defence was that the defendants supplied the cable ordered by the plaintiffs, and were not informed of the particular use to which it was to be put. They further pleaded that the matters in dispute had already been the subject of litigation, which had been settled in the following terms: "August 24, 1893.—Received of W. Culross, Esq., the sum of £20 in full settlement either way of action and counterclaim 'Fowler-Waring Company *v.* Grist.' Defendant to consent to application to stay all proceedings if required. Wood, Bird, and Wood—£20." Mr. McCall, Q.C., and Mr. G. M. Cohen were for the plaintiffs; Mr. Channell, Q.C., and Mr. Wedderburn for the defendants.

The plaintiff's case was, says the *Times*, that in July, 1891, they ordered a 12-wire cable from the defendants, which was to be laid across the Cannon-street railway bridge, so as to enable the plaintiffs' customers to communicate across the river, as many of them had two places of business. So long as only one customer used the cable at the same time everything worked well, but when business increased and two or more customers used it at the same time there were complaints of cross-talk, which the plaintiffs contended was due to induction, arising from the 12 wires being too closely bunched in the cable. The defendants, after investigating the matter, said the mischief was caused by the manner in which the cable was laid and insulated, and they agreed to put a second cable which should be suitable. Meantime the cable company had occasion to sue the present plaintiffs in the Mayor's Court for an admitted balance of account, but there was a counterclaim for damages arising from the unsatisfactory working of the first cable. The action was, however, settled on the terms mentioned above. The second cable was laid in Jauuary, 1893, but according to the plaintiffs no complaints had been made by customers prior to the settlement of the action, nor were they aware of any defects in the cable. On September 11, however, complaints were made, and it was then found that the induction was just as bad as in the first cable, and that, in fact, the two cables were identical except as to the outer casing, which in the second cable was made of a harder substance than in the first.

Mr. Grist, one of the plaintiffs, stated that he always understood he was to be supplied with one of the defendants' anti-induction cables. The defendants were fully aware of the purposes for which he required the cable.

Mr. Gatehouse, electrical engineer, said both the cables were unsuitable for the plaintiffs' work. There was no provision in either of them against induction. Other evidence was given.

The case for the defendants was that they supplied what was ordered according to the specification. They had no knowledge of the cable being used for any special purposes, and certainly never represented either cable to be an anti-induction cable. As to the settlement of the previous action, they contended that the plaintiffs must have been aware of some complaints about No. 2, yet those complaints were suppressed so as to avoid being specifically mentioned in the terms of the settlement, which were to cover the whole of the transactions between the parties.

Mr. Mavor, the defendants' general manager, stated that when No. 1 cable was supplied he was not aware whether it was to be an aerial or an underground cable. No. 2 cable was identical with No. 1, except that it had a hard casing instead of a soft one. That, however, was only to obtain better insulation, as No. 1 had been badly insulated. It had nothing to do with any complaints about induction. In such a cable there was bound to be more or less induction, the only effective means of preventing it being the use of a return wire. Similar cables were in use all over London on the single-wire system, otherwise there was bound to be cross-talk. The use of return wires, however, would double the expense. Cross-examined: When complaint was first made he thought the cross-talk might have arisen from leakage due to bad insulation. He had written to the plaintiffs promising that the second cable should be a suitable one. It might be suitable to plaintiffs' purposes, and yet not suit their customers who used it. Anti-induction cables would be double the price of these cables. He did not intend them to think that they were to be supplied with an anti-induction cable. The use of tinfoil or leadfoil to prevent induction was out of date. The modern plan was to use double or return wires.

Other evidence having been given, and counsel having addressed the jury,

The **Lord Chief Justice**, in summing up, said the main questions were whether the plaintiffs had any claim in respect of No. 2 cable, and if yea, whether that claim was included in the settlement of the Mayor's Court action. They must remember that while, no doubt, there was generally an implied warranty that goods were fit for the purpose for which they were sold, yet if a specific known article was ordered the purchaser was supposed to know what he wanted. A letter of July 22, 1891, would rather tend to show that the plaintiffs were aware of the difference between single lead-covered wire and return-wire cable, for they were asking for a sample of each. It was also remarkable that all parties agreed not only that both cables were perfect of their kind, but also that in both of them there must be more or less induction. That being the case, it was difficult to believe that the plaintiffs really expected to get a low-priced cable absolutely free from induction. It was also curious, to say the least of it, that no tests had been made for induction, and that no customers of the plaintiffs had been called to complain about the cross-talk. The learned judge then reviewed the evidence in detail, and left the following questions to the jury: 1. Did the defendants undertake to supply a cable suitable for telephonic purposes? 2. Did they, in fact, do so? 3. If they did not, what damages? 4. In the settlement of the Mayor's Court action did both parties proceed on the basis that No. 2 cable was satisfactory, and was it intended by them that the settlement should end all questions relating to both cables?

The jury answered the questions as follows: 1. Yes. 2. Yes. 3. No damages. 4. Yes.

The **Lord Chief Justice**: On those findings I give judgment for the defendants with costs.

PRINTING TELEGRAPH AND CONSTRUCTION COMPANY.

In the Queen's Bench Division, before the Lord Chief Justice and a special jury, the case of the Printing Telegraph and Construction Company of the Agence Havas *v.* Beer came up for hearing this week.

This was an action to recover the sum of £980 alleged to be due in respect of calls on shares in the above-named company. The defendant denied that he was the holder of any shares in the company, alleging that the allotment was not properly made, and, further, that he had been induced to take the shares by fraud and misrepresentation.

Mr. Bingham, Q.C., and Mr. Crisp appeared for the plaintiff company, and Mr. Carson, Q.C., for the defendant.

The case as opened for the plaintiff was that the company was formed in 1893 with a capital of £115,000 for the purpose of acquiring and working, through the Agence Havas of Paris, certain receivers and transmitters of general news. The defendant had agreed to underwrite 1,000 shares of £5 each, and, accordingly, the public subscription being very small, the directors allotted to the defendant 980 shares. The application and allotment money on those shares was duly paid, as was also a call of £1 per share, amounting together to £1,960. A second call of £1 per share had since been made, but the defendant had not paid, and the present action resulted.

Before the case had proceeded far the parties came to an arrangement, the terms of which were not stated in court.

SOUTH STAFFORDSHIRE TRAMWAYS COMPANY.

The petition of W. Smallman and others for the winding up of this Company again came before Mr. Justice Vaughan Williams on Wednesday.

Mr. Parker (with Mr. Buckley, Q.C.) said the five petitioners had all been paid with the exception of one, who being an undischarged bankrupt had been improperly made a petitioner; but as the bankruptcy was a good many years ago, and the trustee had never interfered with the trader, he had a right to sue for goods sold and delivered. If the petition were dismissed, the petitioners should have their costs.

Mr. Eady, Q.C., for the company, said all the petitioners would be paid, including the one who had been made a bankrupt, and therefore the petition should be dismissed, with costs.

Mr. Willis Bund, on behalf of debenture-holders who could not get the interest on their debentures, supported the petition.

Mr. Levett, Q.C., for the Electric Construction Corporation, applied to be substituted as petitioners on the petition. The South Staffordshire Tramways Company were hopelessly insolvent. They had given notice to stop working the electric tramways, which was the only part of their system which paid. The Electric Construction Company had a claim of something like £30,000.

Mr. Eady: Which is disputed.

Digitized by Google

Mr. Levett: Yes: and the only reason given is that Mr. Jabez Spencer Balfour was a promoter of my company. They think it a sufficient answer to my claim to say, "Oh! Jabez Balfour was a promoter of your company."

Mr. Justice Williams: Do you gentlemen want me to hear all about Mr. Balfour? Because all I can say is that, having had a great deal to do with his schemes, I think some of them were exceedingly good ones.

Mr. Levett said Mr. Justice Kekewich, in a debenture action, had made an order releasing £7,000 and the electric company wanted these profits to be applied to the payment of their debt

Mr. Eady was anxious that the Electric Construction Corporation should at once bring their action for finding the motive power for the trams, and he would undertake that this £7,000 should remain in court until the trial of their action. On this undertaking the petition ought to be dismissed.

Mr. Willis Bund applied that the debenture-holders should be substituted as petitioners.

Mr. Justice Williams declined to substitute the debenture-holders as petitioners. The debenture-holders could bring a separate petition if they liked. On the tramways company undertaking to give the Electric Construction Corporation a charge on the £7,000 in the debenture action, and paying costs, the petition would be dismissed.

EDMAN v. CHURTON.

This case has been tried at Leeds before Mr. Justice Charles. The plaintiffs were the Rev. Ed. Hudson Edman, rector of Thornton-le-Moor, Caistor, Lincolnshire, and his son, C. E. Harold Edman, and the defendant was Mr. Churton, electrical engineer, of Leeds Damages were sought for an alleged breach of the terms of a deed of apprenticeship, by the failure of the defendant to properly instruct the younger plaintiff in his business. A counterclaim was made by the defendant for the loss of the services of the younger plaintiff. Mr. Scott Fox appeared for the plaintiffs, and Mr. Bairstow for the defendant.

It was stated on behalf of the plaintiffs, that in 1891 the younger plaintiff, who was a minor, was apprenticed to Mr. Churton to learn the business of an electrical engineer. In 1893 he went home ill, and it was alleged that this was due to overwork and that he had not yet fully recovered his health. He stated that during his residence with Mr. Churton he had learned next to nothing. He admitted, in cross-examination by Mr. Bairstow, that no dispute or dissatisfaction arose, except in his "secret mind," at the extent of his instruction, until a dispute arose between his parents and Mr. Churton as to the amount due for his board. His father was very hard up, and was not able to pay the amount agreed upon. In the course of the dispute a letter was written to Mr. Churton by Mrs. Edman, wife of the senior plaintiff, saying that her son was very comfortable at Mr. Churton's, but that she could not afford to pay the terms for board previously arranged.

After hearing the evidence, his **Lordship** gave judgment for the defendant, remarking that the case was one which ought not to have been brought.

Mr. Bairstow, addressing the judge at the opening of the court after the adjournment, said that having regard to his Lordship's views, the defendant was disposed to relinquish his claim for costs.

His **Lordship** said that in that case the defendant had behaved very handsomely; it was an act for which he deserved the greatest credit.

JEFFREYS v. PRITCHARD AND GOULD.

On Monday, in the Westminster County Court, his Honour Judge Lumley Smith, Q.C., and a jury had before them this case, in which the plaintiff sued, under the provisions of the Employers' Liability Act, to recover damages for personal injuries sustained whilst in the employ of the defendants, a firm of electrical engineers carrying on business in Soho.

From the opening statement of Counsel it appeared that on the 16th of October last the plaintiff was employed in conjunction with other men in fitting up the electric light at a house in Hanover-square. and for the purpose of fixing up the wires he was ordered to do his work from the roof of a lift which ran down a well in the centre of the premises. While he was so engaged the lift was moved by the foreman or one of the men on the job and gave a sudden jerk upwards, with the result that the unfortunate plaintiff was thrown down and sustained a fracture of the back, from which he would never again recover. From first to last he was acting under the instructions of the foreman, and although he did not approve of working on the top of a lift he was obliged to do it. The plaintiff, it was stated, was still too ill to leave his bed, and probably never would do so again, and accordingly his evidence, which was now read, had been taken on commission.

The **House-Surgeon** of the hospital was called, and said the injuries to the back were of such a character that the man would never be able to leave his bed again, and although a careful operation had been performed he was in a worse condition than he was when admitted, and the continuance of life only depended on the most careful nursing and general attendance.

The defence was that the work which the plaintiff was given to do could have been done with absolute safety had proper care been used, and a number of expert witnesses were called in support of the defendants' case to prove that it was a very common thing when fixing up electric light wires to carry out the work from the roof of the lift and raise and lower it as necessity arose.

Plaintiff's **Counsel**, in addressing the jury, submitted that it was a highly improper thing to put any man to do work of this kind under such dangerous conditions, and the plaintiff had previously complained about it, but was told that if he did not like to do it someone else would.

His **Honour** said the question was as to whether or not the defendants' plant was defective by reason of the absence of a hand-rail on the top of the lift, and was the accident caused thereby, but there was a second question as to whether or not the plaintiff had been guilty of contributory negligence, because if so he would not be entitled to recover damages against defendants.

After a hearing which occupied practically the whole of the day the jury found a verdict for the plaintiff, and assessed the damages at £150

Judgment was so entered, with costs.

IMMISCH ELECTRIC LAUNCH COMPANY v. WHITE.

Before Judge Holl, at the Windsor County Court on Friday, an action was brought by the Immisch Electric Launch Company, Limited. against Mr. F. W. White, of Windsor, to recover £21. 9s. 6d as compensation for damages caused to the "Viscountess Bury" launch through the alleged negligent navigation of the defendant's vessel

The **Plaintiffs** stated that while the "Viscountess Bury" was being pushed away from the Windsor landing place, upon the occasion of the races, the "Amo" came astern before she had time to get away. and a collision occurred.

For the defence it was contended that the "Amo" was waiting for the "Viscountess Bury" to go out, that she was not being pulled astern, and that the collision was really caused by the "Viscountess Bury" getting too much across stream while attempting to go through the centre arch of Windsor Bridge.

The **Judge** decided in favour of the plaintiffs and allowed the amount claimed.

COMPANIES' MEETINGS.

ELMORE'S GERMAN METAL COMPANY, LIMITED.

The third annual general meeting of the above Company was held on Wednesday at Winchester House, Mr. John McFarlane presiding.

The **Chairman** stated that the loss of £12,076 8s. 2d shown in the metal balance-sheet did not represent the loss for the one year, 1893, but for the period since the formation of the Company, and it is all but covered by the profit of £11,750 made by the German and Austro-Hungarian Company in 1894, and referred to in the report submitted with the accounts. A great advance had been made as compared with 1893 There were no bad debts The preference share issue had been a success. and there was a reduction in the debenture liability. He was sanguine as to the future of the Company. He moved the adoption of the report and accounts.

Mr. John Heal seconded the motion, which was carried.

NEW TELEPHONE COMPANY, LIMITED.

An extraordinary general meeting of this Company was held on Wednesday at the Cannon-street Hotel to consider a resolution for winding up the Company voluntarily. Mr J. S. Forbes presided

The **Chairman** stated that the purpose for which the Company was created had been served, and experience showed that the interests of the telephone business and of the public would be better served by having the complicated work which had to be performed carried on by one company instead of by two. The New Company had accepted certain obligations to individual subscribers, and they had carried these out loyally but the time had now come when it was thought that it would be much better for the New Company to be wound up The places in which business had been carried on were very few, and the business itself was on a comparatively small scale. The capital of the Company subscribed and paid up was, however very large, and a good deal of it was lying aside absolutely unproductive. They felt that this capital ought to be restored to those to whom it belonged He concluded by moving the resolution.

After some discussion the motion was adopted.

British Aluminium Company.—The British Aluminium Company, Limited, is a new Company with a share capital of £300 000, divided into 20,000 7 per cent. cumulative preference shares and 10,000 ordinary shares of £10 each. Fifteen thousand 7 per cent. cumulative preference shares have this week been offered for subscription. The preference shares will also be entitled to one-half of the surplus profits after the ordinary shares have received a dividend at the same rate, and to priority in distribution of capital. The Company has been formed for the purpose of making aluminium in this country by an electrical process now carried on by the Société Anonyme pour l'Industrie de l'Aluminium de Neuhausen (Aluminium-Industrie-Actien-Gesellschaft) in Switzerland, and by the Société Electro-Métallurgique Française at Froges (Isère, France), and of carrying on the manufacture of aluminium and its alloys.

Digitized by Google

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Scarborough.—The Lamps Sub-Committee of the Town Council have been instructed to obtain tenders for the lighting of certain streets in the borough by electricity.

Portsmouth.—The Town Council invite tenders for the purchase of certain electrical plant at the Town Hall, Portsmouth. We have already given particulars. Tenders must be sent in by to-morrow (22nd inst.).

Edmonton.—Tenders are invited for the supply, delivery, and fixing of a system of electric call bells and telephones, for fire brigade and Local Board purposes, for the Edmonton Local Board. Tenders must be delivered by noon to-day. We gave particulars last week.

Walsall.—Tenders are invited for alterations to buildings at the Wolverhampton-street gasworks, including the construction of boiler-house, dynamo-house, offices, and other works for an electricity generating station, for the Corporation. Tenders are to be sent in by the 24th inst.

Great Yarmouth.—Tenders are invited for installing the electric light at the Town Hall, free library, and Great Yarmouth police station, for the Town Council. Drawings and specifications can be seen and forms of tender can be obtained at the office of Mr. J. W. Cockrill, A.R.I.B.A, A.M.I.C.E., borough surveyor, Municipal Buildings, Great Yarmouth. Tenders, to be separate for each building, to be upon the form and in the envelope supplied, are to be delivered at the office of Mr. T. M. Baker, town clerk, before noon on January 2.

Birmingham.—The committee of the Birmingham Municipal Technical School invite tenders for the installation of the generating plant, fittings and appliances for both the electric lighting and transmission of power by electricity in the new school. Plans of the building may be seen, and specifications and forms of tender obtained, at the offices of Messrs. Hy. Lea and Thornbury, consulting engineers, 38, Bennett's-hill, Birmingham, on a deposit being made with them of £2. 2s., which will be returned on receipt of a *bonâ fide* tender. The committee do not bind themselves to accept the lowest or any tender, and no tender will be considered except upon the prescribed form and accompanied by an undertaking that not less than the minimum standard rate of wages current in the district is paid by the contractor and sub-contractors (if any). All tenders must be sent in to Mr. Geo. Mellor, secretary, endorsed "Tender for Lighting," on or before January 12.

Hanley.—The Corporation of Hanley are prepared to receive tenders for the supply and erection of the following plant: Contract No. 10—extension of engine-house plant, including 200-kilowatt alternator, 25-kilowatt alternator, and 20-kilowatt exciter, each separately driven by a compound steam-engine, with all necessary steam and exhaust pipes, valves, switchboard, and appurtenances; Contract No. 11—extension of condensing plant, consisting of circulating pump, air-pump, boiler pump, surface condenser, with all necessary pipes and appurtenances. The drawings can be inspected, and specifications, prepared by Mr. G. H. Cottam, Corporation electrical engineer, together with general conditions and forms of tender, can be obtained at the offices of Mr. Joseph Lobley, Town Hall, Hanley, on payment of 5s. Tenders are to be delivered to Mr. Arthur Challinor, town clerk, on or before January 5, 1895. The Corporation do not bind themselves to accept the lowest or any tender.

RESULTS OF TENDERS.

Worcester.—The tender of Messrs. Verity and Sons has been accepted for the substitution of three electroliers for three sunlights in the assembly-room at the Guildhall, with wiring, at the price of £49. 12s. 9d.

Enniscorthy (Ireland).—The tender of Messrs. W. Curtis and Sons, Middle Abbey-street, Dublin, has been accepted for providing the Enniscorthy District Lunatic Asylum with internal telephonic communication.

Aberdeen.—The Gas and Electric Lighting Committee of Aberdeen Town Council have held a meeting to consider the tenders lodged for the supply of a new engine, dynamo, and other necessary plant for the extension of the electric lighting system. A report by Prof. Kennedy, London, to whom the tenders had been submitted, contained an analysis of the specifications. In Prof. Kennedy's opinion the offer of Messrs. J. H. Holmes and Co., Newcastle, which amounted to £3,300, was the best and cheapest, and the committee decided to accept that offer. The tenders sent in were as follows:

Johnson and Phillips	£3,860
Mather and Platt, Limited	3,820
Electric Construction Company, Limited ...	3,742
Easton, Anderson, and Goolden, Limited ...	3,600
Siemens Bros. and Co., Limited	3,578
Crompton and Co., Limited	3,493
J. H. Holmes and Co.	3,300

City and South London Railway.—The receipts of the Company for the week ended December 16 were £962, against £909 for the corresponding week of 1893, or an increase of £53. The total receipts for the current period of the present half-year amount to £21,479, as against £20,097 in the corresponding period of 1893, an increase of £1,382.

BUSINESS NOTES.

Blackburn.—The use of the electric light is extending.

Cheltenham.—Enquiries are being made as to the probable cost of lighting the library by electricity.

Belfast.—The electric light has been installed in the Empire Theatre.

Milford Haven.—The electric light has been installed in St. Catherine's Church.

Rimington.—The electric light has been introduced into Newby Mill, there being 45 16-c.p. lamps employed.

Hucknall.—The chairman of the Local Board has stated that he hoped the town would soon be lighted by electricity.

Hove.—The Library Committee of the Town Commissioners have rearranged the electric light in the reference-room.

Appointment.—Mr. Ross Cotton, of London, has been appointed assistant electrical engineer to the Local Board, Halifax.

Whitechapel.—The new Pavilion Theatre, which is to be opened on Boxing Day, will have the stage lighted electrically.

Plymouth.—There has been some conversation in the Borough Council as to whether the Theatre Royal ought not to be lighted by electricity.

Eastern Telegraph Company.—For the quarter ended September 30 an interim dividend of 2s. 6d. per share is announced, payable on January 14.

Harrow.—A ratepayers' meeting has passed a motion asking the Harrow Local Board not to proceed any further with the electric lighting question.

Kilwinning.—Nine 16-c.p. lamps have been fitted in the underground passage at Messrs. William Baird and Co.'s Lady Sophia pit. There are 24 larger lamps on the surface.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 16th inst. amounted to £917, as compared with £634 in the corresponding week of last year.

Coventry.—On the recommendation of the Electric Light Committee, the City Council have resolved to charge 4d. per Board of Trade unit for current supplied for other purposes than lighting.

Wakefield.—Mr. Lee, the chairman of the Electric Lighting Committee of the City Council, has stated, in reply to Mr. Sherwood, that the committee had not yet done any actual business in regard to electric lighting.

Yacht-Lighting.—The twin-screw steam yacht "Giralda," which has been built by the Fairfield Company, of Govan, for Mr. McCalmont, is lighted electrically, and has two search-lights of the Admiralty pattern.

Burton.—The following are the members of the new Gas and Electric Light Committee of the Town Council: Alderman Lowe, Councillors Austin, Auty, Cain, P. Evershed, Graham, T. E. Lowe, Metcalfe, Morris, Blackhall, Oliver, and Turner.

Harrogate.—The following have been appointed members of the Electric Lighting Sub-Committee: the Mayor, Aldermen Hammond and Simpson, Councillors Chippendale, Hudson, Morrison, Oxley, Simpson, Thwaites, and Ward.

Woking.—The surveyor reported to the Local Board last week that he had had an interview with Mr. Mayne, and while no positive guarantee would be given, the electric light company expected to have everything finished by December 22.

Bedford.—The electric light is creating a very favourable impression in the town. Among the buildings lighted are the Town Hall, the Council-chamber, and the Modern School Hall. The heaviest load on the station has been equal to about 14,400 c.p.

Heywood.—Councillor Chadwick, at a meeting of the Town Council, stated that he should like the Gas Committee to take into their serious consideration the question of preparing for the adoption of electric lighting in the town. Other members spoke to similar effect.

Forfar.—Mr. Forbes Waddell, the new Corporation gas manager, states that as the electric light has now been adopted in most of the factories in Forfar, the sale of gas under that head has steadily decreased from 7,500,000 cubic feet in 1891-92 to 3,000,000 cubic feet in 1893-94.

Liverpool Electric Supply Company.—The Lighting Company of the Liverpool Corporation have decided to recommend the Council to offer to purchase the undertaking of the Liverpool Electric Supply Company instead of waiting until the time arrives when the Corporation can compel the Company to sell.

Fire Brigade Communication.—The Fire Brigade Committee of the London County Council reported on Tuesday that they had sanctioned the establishment by Messrs. Strode and Co., at a cost of £27, of electrical communication between the Tooting fire-engine station and lodgings occupied by men attached to that station.

Aberdeen.—A sub-committee of the Town Council have been instructed to take the requisite steps for having the fire stations electrically connected with the house of each fireman, with the offices of the gas and water departments, telephone exchange, and with special telephone between the police office and fire station.

Electric Battery Company, Limited.—This Company has been registered with a capital of £30,000 to adopt an agreement, made December 7, 1894, between H. T. Barnett of the one part and T. J. Moffett, for the Company, of the other part, and to manufacture and deal in batteries, motors, etc., in accordance with certain patents to be acquired by the Company.

Digitized by Google

Metropolitan Electric Supply Company, Limited.—This Company announces the payment by warrants on January 1 next of interest from July 19 last (or from the respective dates of payment of instalments) to December 31 on the 4½ per cent. first mortgage debenture stock. The transfer books are closed from December 18 to December 31, both days inclusive.

Victoria Electric Railway Company.—The numbers are published of the 5 per cent. first mortgage debenture bonds of the Victoria Electric Railway and Lighting Company, Limited, amounting to £1,000, which have been drawn for repayment on and after January 2, 1895, at the rate of £105 per cent., in accordance with the provisions of the trust deed.

Islington.—At a meeting of the Vestry a report was received from the Special Electric Lighting Committee recommending that the offer of the lessee of 5, Burnard-place, to assign her interest and to give possession of this house to the Vestry upon payment of the sum of £350, and her surveyor's fees under Rhyde's scale, be accepted subject to a good title being shown. The report was agreed to.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,937. The following telegrams have been received by the Western and Brazilian Telegraph Company, Limited, from their representative in Rio de Janeiro: "12th—Bill passed second reading Upper House yesterday;" and "14th—Purchase passed third reading in Senate yesterday, and sent to President for sanction."

New Swindon.—The clerk to the Local Board has produced a draft of the provisional order for lighting the district electrically, and suggested that the streets to be included in the first draft should be what he might term the "inner circle"—Bridge-street, Regent-street, Regent-circus, Commercial-road, Milton-road, Farringdon-street, and Fleet-street. On the proposition of Mr. Longland, seconded by Mr. Batt, it was resolved to include these streets.

Worcester Extension.—The contract for lighting the works and offices of Messrs. Hill, Evans, and Co. with electricity has been entrusted to Messrs. B. Verity and Sons, through their agents, Messrs. Alfred Mann and Sons, of High-street. The same firm have also secured the order for the fittings required in the Shire Hall and Law Courts. The electric pumps recently fixed at the waterworks are now pumping water to the high-level reservoirs at Elbury Hill, and are performing the work in a satisfactory manner.

Bristol.—The Electrical Committee met at the Council House on Friday, when there were present Mr. George Pearson (in the chair), Alderman Pethick, Councillors Bastow, Hill, Hughes, Lloyd, Pembury, Tryon, and Wills The committee determined not to extend the main along Boyce's-avenue and the west side of Victoria-square at present The engineer informed the committee that Mr. Duncan, one of the improvers, had secured an appointment as assistant engineer at the Cheltenham Corporation electric light works.

Ayr.—The engineer reports that the new site in Mill-street for the electric installation at Ayr was proving from the borings a most excellent one. Without any extra expense beyond the ordinary excavation, the Council would be able to arrange for the foundations to rest upon the solid rock. The cost of the site is £1,550. The Ayr Harbour Trustees have been offered by Ayr Town Council a supply of electric light for the harbour, on condition that the trustees provide the lamps and other plant required, and pay at the rate of 4d. per unit.

Luton.—Mr. Wilkinson, at a meeting of the Town Council, proposed that a memorial be forwarded to the Board of Trade, praying for the grant of a provisional order for the supply of electricity in the borough, in the terms of the draft proposed order, or as the Board of Trade deemed fit. Mr. Smith seconded, and the motion was carried with one dissentient. The clerk read the borough surveyor's estimate for carrying out the scheme—viz., £10,000. It would also be necessary to send a cheque for £50. It was resolved that the documents and the cheque be sent to the Local Government Board.

Carlisle.—The minutes of the Gas Committee of the Town Council showed that the engineer had reported to the committee that the town clerk had forwarded communications respecting the Carlisle electric lighting order, and that he had been instructed to confer with the town clerk on the draft provisional order submitted. The minutes also showed that the committee had passed resolutions that the sum of £40,000 be the amount asked for in the Carlisle electric lighting provisional order, and that the sum of £100 be remitted to Messrs. Mellor, Smith, and May on account of expenses in connection with the electric lighting order. The minutes were confirmed.

Brayton Petroleum Motor Company, Limited.—This Company has been registered with a capital of £80,000 to acquire letters patent granted, or to be granted, to Hugh Thompson Reid by the Governments of Germany, France, Belgium, Italy, Spain, Austria, Russia, and India for improvements in hydro-carbon engines, and the inventions therefor, and also any improvements already made, or hereafter to be made, in the said invention; to acquire any other patents and inventions which may seem capable of being turned to account by the Company; as iron, brass, and other metal founders, fitters, engineers, toolmakers, millwrights, colliery owners, chemists, etc.

Llandudno.—Mr. William Williams, in supporting a vote of thanks to Mr. John Jones, the chairman of the Improvement Commissioners, alluded particularly to the chairman's action with regard to the electric light. He stated that it was due to the chairman's energy that the local authority had the power to carry out an electric light undertaking. At a special meeting of the Llandudno Improvement Commissioners, held on Tuesday, the seal of the Board was ordered to be attached to a memorial to the Board of Trade upon the grant of a provisional order to supply electricity within the Commissioners' district, and a cheque was drawn to cover preliminary expenses.

City of London Electric Light Company.—The warrants for the interest payable on January 1, 1895, at the rate of 5 per cent. per annum for the six months ending 31st inst., on the City of London Electric Lighting Company's first issue of £100,000 debenture stock will be posted on the 31st inst. The directors of the Company announce the further issue at £128 of £200,000 5 per cent. debentures redeemable at the option of the Company at £125 on six months' notice after 1910, and secured as a first charge by way of floating security upon the whole undertaking. The Company has a capital of £800,000; the gross annual revenue is estimated at over £100,000, and the amount expended to the end of October on land, buildings, plants, etc., was £963,571.

Halifax.—Mr. Wilmhurst and his staff have been busy extending the Corporation electric light supply to business and other establishments in the town, and between 20 and 30 customers are now having their premises illuminated from the works in Foundry-street. Among those in enjoyment of the privilege are the Masonic Hall, Messrs. T. Simpson and Sons, Messrs. Hodgson, Messrs. Whitley and Booth, Mr. G. Davis, Mr. C. E. Rose, Mr. F. Buckley, Messrs. Seed Bros., and Messrs. Murgatroyd and Horsfall, in addition to Trinity-road Baptist Chapel, which was lighted up with the electric light for Sunday evening's service. From first to last not a single hitch has been experienced with the machinery. Messrs. Ullerthorne and Hartley, electricians, have a brilliant electrical display at the shop of Mr. Ward, plumber, Broad-street, the latter of whom is among the present customers of the Corporation.

The "Cruto" Incandescent Lamp.—Under the title of the Cruto Incandescent Lamp Agency, Limited, of Dock House, Billiter-street, E.C., a company has been formed to acquire the sole agency for the supply in the United Kingdom of the incandescent lamps manufactured by the Societa Italiana di Elettricita Sistema Cruto, of Turin. The feature of the latter's factory is that the whole of the air-pumps and other machinery required in the manufacture of the lamps are driven by water power, and the company consequently claim that they are able to manufacture lamps of the highest possible quality at a moderate price. The Cruto lamp consumes 3·2 watts per candle per hour. This fact, the company state, combined with a life of 900 to 1,000 hours, makes it the cheapest lamp obtainable. The Cruto lamp has been awarded medals at various exhibitions, and, after exhaustive tests, it has been adopted for the Italian navy.

Leith.—A preliminary test has taken place of the plant which has now been all but completed for the electric lighting of the Victoria Dock and the Old Docks, Leith, the Commissioners having decided to have the plant subjected to trial at these docks before extending it to the Albert and Edinburgh Docks. The machinery has been placed in a building adjoining the Commercial Graving Dock. The generating plant consists of two engines and two large dynamos. The lighting is to be done by means of arc and incandescent lamps, large arc lights being suspended from poles on the quays and from the side of the sheds, and smaller ones being hung inside of the large sheds, with incandescent lights of a smaller size on the south side of the Victoria Dock. The plant is expected to be completed and ready for operation in about a week. The installation of the electric light, which has cost about £4,000, has been carried out by the Brush Electric Lighting Company, under the supervision of Mr. E. G. Craven, superintendent for Scotland.

Swansea.—The General Purposes Committee of the Swansea Corporation have decided to light the compulsory area by electricity on the high-tension alternating-current system, and to use a refuse destructor in combination therewith. The streets comprised in the compulsory area are: Quay-parade, Mount-street, Wind-street, Castle-square, Castle Bailey-street, Temple-street, Castle-street, High-street, Alexandra-road, Grove-place, De la Beche-street, Cradock-street, Union-street, Oxford-street, Dillwyn-street, Northampton-place, Goat-street, and Caer-street. The sub-committee have reported that they have consulted Mr. Manville, of London, who had estimated the cost of lighting the town by electricity at about £47,000. The question of the site of the works was not gone into for the present. The report was adopted, and it was decided to place the work in the hands of Mr. Manville at a remuneration of 5 per cent. on the estimated outlay. The question of the acquirement of the tramways by the Corporation was gone into, and a sub-committee appointed to report upon the scheme to the whole of the committee.

City.—The City Commission of Sewers held a meeting on Tuesday, when Mr Johnson enquired whether any progress had been made towards securing an advantage to the public by means of a bargain with the City Electric Lighting Company for the use of the telephone tubes, or whether there was any fear that by undue delay the Commission might be placed in a false position. Mr. Burmester, in replying, explained that in July Mr. Gordon placed on the paper of business a motion to accept an offer of the company for the use of the tubes in question, but that offer was not officially before the Commission, so it could not be described as a bargain. But the sense of the Commission was against any such offer, notwithstanding that it was one which, in his opinion, should have been accepted, it being somewhat in excess of what the company was prepared to offer originally. The question was, how-

Digitized by Google

ever, still before the Streets Committee. The clerk read a letter from the solicitor to the London County Council, asking the Commission to assist the Council in an enquiry as to the number of transformer stations in the City. Mr. Baylis said he thought there could be no objection to the giving of the information. The Court concurred.

Kingston-on-Thames.—Major-General C Phipps-Carey has held a Local Government Board enquiry into the application of the Corporation of Kingston for an extension of the municipal boundaries so as to include the whole of the civil parish of Kingston and the adjoining parish of Ham. In the course of the enquiry Mr. W. H. Preece was called, and in reply to Mr. Bidder, Q.C., he said he had examined the electric installation of the Corporation of Kingston. They had consulted him in reference to it, but not professionally. He believed it was quite an "up-to-date" installation. Assuming that Surbiton and the other districts surrounding the borough required lighting by electricity, it would be more advantageous and cheaper to supply them from one central station than from a number of independent stations. If they had three or more separate installations in the district it would involve a much greater expense in plant. The Kingston works readily lent themselves to extension. A much less number of men would be required on the working staff at one central station than at a number of separate stations, and only one set of machinery would be necessary. The Kingston works escaped the floods; the machinery never stopped.

Edinburgh.—The Lord Provost's Committee of the Town Council are considering whether it is advisable to lay down high-tension cables from the central electric light station to Nicholson-street. At Tuesday's meeting of the Town Council Mr. Auldjo Jamieson, in accordance with notice, asked the convener of the Electric Lighting Committee (1) what was the reason of the delay in the completion of the electric lighting system of the city, (2) when was it confidently anticipated that the system would be introduced and the supply afforded to intending consumers? Mr. Mackenzie replied that the reason of the delay was mainly in consequence of the Corporation having wisely decided to make the power station sufficiently large to accommodate all the machinery which might be required to light the whole of Edinburgh. As to the second branch of the question, he might state that Prof. Kennedy had been in Edinburgh on the previous day, and in answer to a question stated that from the progress of the work he saw no reason for changing the opinion he had expressed two or three months previously, that they would have the current turned on in the month of March. Prof. Kennedy was certain that they should have the current turned on then. He (Mr. Mackenzie) did not commit himself to the beginning, the middle, or the end of March, however. They would not have the whole of the public lighting started by March, but they would have Princes-street in full blaze. The new dental hospital which has been opened in Chambers-street is lighted electrically.

Cardiff.—A meeting of the Cardiff Lighting Committee has been held under the presidency of Alderman Fulton. Tenders for a six months' supply of steam coal for the electric lighting station at Canton were received. Fifteen estimates were sent in, but the selection was deferred. A letter was read from Mr. Yeaman, the newly-elected engineer, regretting that his employers, the Croydon County Council, would not release him from work at so short notice, thus preventing him from entering on his duties at Cardiff till the beginning of next year. It was decided to communicate with Mr. Yeaman, asking him to acquaint the committee with the earliest date on which he could come to Cardiff. At a meeting of the Lighting and Electrical Committee of the Cardiff Corporation on Tuesday morning, under the presidency of the Mayor (Alderman P. W. Carey), attention was called to the necessity of lighting up a number of back lanes in various parts of the town, but the Mayor suggested that the responsibility of taking this step should rest with the Council. If they once began to light up back lanes it would mean a considerable expense, as there were some scores of such lanes in the town. There were also many of the principal thoroughfares which were at present badly lighted, and these needed attention first. The recommendation of the borough engineer to erect new lamps in certain streets was adopted. Mr. W. H. Massey said his attention had been called to a letter in which complaints were made about the irregular nature of the incandescent light. If there had been any irregularity the committee ought to know it, but, if not, such damaging statements ought not to be made. Mr. Harpur knew whether the light had been working regularly or irregularly. Mr. Harpur said there had not been any irregularity, and he had not had a single complaint from any customer.

Portsmouth.—The third direct-driven alternating dynamo, a duplicate of those already in use at the Portsmouth electric lighting works, is rapidly being put in position. Messrs. Yates and Thom, the builders of the driving engine, say that no engine of the kind has ever been put out in the time. The dynamo, which has been built by Messrs. S. Z. de Ferranti and Co., now remains to be erected, and under the terms of the contract, unless the engine is in running order by Christmas Eve the contractors are liable to a fine of £100 apiece. There is no doubt, however, that barring accidents, the dynamo will be in complete running order by the day named. The work has been much facilitated by the fact that the Electric Light Committee had a third foundation built at the time that the first two engines were erected, thus avoiding the danger involved in doing the brickwork close to the moving machinery. The new engine is of 330 h.p., and the dynamo has a capacity of 5,000 16-c.p. lights, but the applications as yet made are considerably below that limit. There will be a great advantage, however, in the fact that there will be a spare engine should any breakdown occur. For the past few weeks the engines have been working up to their full capacity, and the fact that a slight breakdown would mean the shutting off of some of the lights, has been a source of no little anxiety to the engineers. Alderman Ellis, the chairman of the committee, states that after Christmas it is hoped to considerably extend the electric lighting area, and that estimates are already being prepared with a view to the proposed extension. A large number of applications has been received from residents and tradespeople outside the prescribed area—principally in Marmion-road and Castle-road, Southsea, Arundel-street, Landport, and at North End. The engine-room affords space for no less than eight dynamos similar to those now in use.

Radcliffe.—The Local Board have had a meeting at which it was reported that a committee had resolved that the seal of the Board be affixed to a memorial to the Board of Trade, asking for a provisional order giving the Board power to apply for borrowing powers to borrow money to carry out the proposed system of electric lighting. In the course of a discussion which ensued, the Chairman stated that it was very likely the committee would decide to ask for borrowing powers for £20,000. He did not think it was likely that such a sum would be borrowed. In answer to Mr. Brooks, the Chairman said that the amount of money likely to be asked for would be inserted by the Electric Lighting Committee. They would probably ask for £20,000, but they might not spend £5,000. Mr. Brooks objected to this proceeding, and contended that before the seal of the Board was attached to the memorial the committee should meet and agree as to what amount should be asked for, and their recommendation should come before Board and considered as part and parcel of the memorial. The Chairman intimated that the memorial had to be in by a certain date. Mr. Brooks: It is the first time such a thing has been attempted to my knowledge, and I shall object to the committee deciding what amount shall be asked for without the Board considering that matter. The Chairman: It is the first time we have had to deal with such a thing as sending a memorial within a certain time to an authority in London. It was explained that it was absolutely necessary that the memorial should be in London by a certain date, but although the committee would ask for powers to borrow £20,000, it did not follow that they would borrow anything like that amount, and the Board would have to sanction any application to the Local Government Board for an order before it was made. The resolution as mentioned was agreed to, and the matter dropped.

Ealing.—Mr. C. Jones, the surveyor to the Local Board, has stated that 63 applications had been received for private installations of the electric light, these applications being for 4,000 8-c.p. lamps. In regard to these applications, 44 connections (2,649 lamps) had been made. Some 39 of the public arc lamps were now in working order, and between 60 and 70 gas lamps in the streets into which the electric light had been introduced had been extinguished. The surveyor was questioned as to delays that had occurred in repairing the paths that had been disturbed by the laying of the electric light mains, in erecting the arc lamps along the Uxbridge-road, and in making the private installations applied for. In response to these questions, he stated that he was endeavouring to come to an arrangement by which the paths would be temporarily repaired until the spring, when they could be permanently retarpaved; the delay in the making of the private connections was due to a want of transformers; and the non-erection of some of the lamps along the Uxbridge-road was owing to the non-delivery of the iron standards. The surveyor added that, compared with the time that had been occupied in effecting electric light installations in other towns, the work in Ealing had been rather quickly pushed forward. As regarded the private installations, the installations were made according to the date of the applications for them, priority being given to the applications that were first received. The Chairman said he had also heard complaints of delay in making the private connections. He thought, however, that the Board had done fairly well in bringing the scheme to the point of completion it had reached within the period the work had occupied. The clerk was directed to write urging that the standards required for the public arc lamps should be furnished as quickly as possible.

Glasgow.—For some considerable time past the Glasgow Post Office authorities have been much hampered by the lack of accommodation afforded by the present premises in George-square, and during the past four years a large building has been erected on ground in Ingram-street, to the south of the building, to meet the increasing requirements of the department. This building has now been completed, and will be used for the first time in connection with the extra work which falls to be dealt with at the Christmas season. One of the first buildings in the city to adopt electric lighting, the current in the post office has been obtained from the city supply station. Owing to the additional supply of current required in the extended building, the question of laying down the generating plant necessary for the lighting of the whole building was at an early stage considered by the Post Office authorities, and the estimates were prepared by Mr. W. H. Preece, C.B., F.R.S., the engineer-in-chief to the Department, which showed that a large saving would be effected by following that course. The work of carrying out Mr. Preece's specifications has now been completed. The new plant has been erected in the basement of the new block, and has this week been brought into use. Every modern improvement has been utilised by the authorities, and when the telegraph department move into the new building in the course of a few months it is proposed to use the current generated by the new dynamos for working all the telegraph instruments at the head office, 5,000 primary cells being replaced by 250 secondary cells.

Digitized by Google

By this means a very large saving in the cost of maintenance will be effected, as the primary batteries at a busy office like Glasgow require constant attention, and their elements require frequent renewal. All the work has been carried out under the supervision of Mr. E. Ashton, superintending engineer of telegraphs for the western district of Scotland.

Elmore's American and Canadian Patent Copper Depositing Company.—"A Shareholder" writes to the *Financial News* as follows on the subject of this Company: "Having regard to the impossibility of obtaining satisfactory or definite information with regard to the progress of this Company, I venture to trespass upon your space with a view to bring to the recollection of other shareholders a company which, were it not for the losses it seems likely to entail upon numerous persons, might very easily be forgotten. In the prospectus dated January 26, 1892, was intimated the intention of the Company to erect in New York 'plant of a sufficient size to demonstrate, on a working scale, the merits and simplicity of the invention, the extraordinary low cost of manufacture, and the enormous advantage to users of the articles when so made.' In a later paragraph the directors expressed their great satisfaction in announcing that Messrs. Jere. Abbott, and Co. had accepted the commercial agency for the United States In a circular letter dated October 31, 1892, issued 'by order of the Board,' it was stated that after careful consideration and conference with Messrs. Jere, Abbott, and Co., the Board decided that the interests of the proprietors would be best served by postponing the erection of a trial plant in America, the reason being that the Board was convinced that the mere erection of such plant and the demonstration of the process on a comparatively small scale would be insufficient to effect a re-sale of our property. No doubt many, like myself, desire to ascertain what chance, however remote, there may be of obtaining some return for our money; and as the directors do not seem to be exhibiting any undue haste in giving effect to their anxiety to meet us in general meeting, you may bring the matter before somebody competent and willing to afford some reliable information. It would be a source of gratification to know who, if anyone, besides the vendors and promoters, is likely to obtain any pecuniary benefit from a company the avowed objects of which have been so ingeniously conceived and so brilliantly carried out."

Warwick.—An electric light installation has been completed at Warwick Castle. Every portion of the castle is lighted, and about 500 lights are altogether used. In lighting such a historic place as Warwick Castle great care was required to be exercised as to the manner in which the wires were introduced into the various apartments and also in the disposition of the lights themselves, so that they should be in harmony with the style of the place. In all the state apartments and in the large hall the electric lamps have been adapted to the existing chandeliers and wall brackets, in most cases being fitted on imitation candles and prettily shaded with white silk shades, so that the general effect of the old style of lighting is retained. In the private apartments the same plan is adopted, the lights being fitted in shaded lamps of various descriptions, giving a soft and pleasant light. The whole of the bedrooms are lighted and also the servants' quarters, gas being entirely dispensed with. A special feature has been made of the lighting of the approach from the lodge to the castle, electric lamps being placed as to thoroughly light the carriage drive. These lights are controlled both from the castle and the lodge, so that they can be turned on or off in a moment from either end of the drive when required. The electric current for supplying this large number of lights is generated by machinery placed in the old mill close to the castle, the motive power being obtained partly from a turbine worked by the River Avon, and partly by means of a gas engine. There are two dynamos, each capable of supplying 250 16-c p. lamps, one being attached to the turbine and the other to the gas-engine, the latter being specially held in reserve for times when the water power may be deficient in times of drought or flood. An accumulator is provided for storing a sufficient amount of current for use when the dynamos are not working, so that the light is available for use at all hours, both by day and night. The whole of this installation has been carried out, under the consulting engineer, Mr. Vaughan Fowler, M I.E.E., by Messrs. Edmundsons, Limited, of Great George-street, Westminster. The turbine has been supplied and fitted up by Messrs. Gilkes, of Kendal.

Brighton.—A report of the engineer, Mr. Arthur Wright, which was considered yesterday by the Town Council, is dated December 10, and says: "As the arc lighting of the principal streets at our present prices will be so little in excess of the price at present paid for gas, and the improvement in the illumination will be nearly as great as that which was effected by the electric lighting of the King's-road, I recommend the committee to at once make arrangements for lighting the following principal roads and streets by means of arc lamps—viz., Queen's-road, West-street, Western-road, North-street, East-street, Preston-street, Old-steine, St. James's-street, Marine-parade, North-street Quadrant, part of Ship-street, and the central valley northwards to New England-road. On the supposition that the committee decide to adopt my recommendation, the scheme would involve the use of 115 six-ampere arc lamps, 40 of which I propose should be extinguished between 11 and 12 o'clock at night, the remaining 75 being burned all night. The capital outlay required for the above 115 arc lamps will depend to a certain extent upon the designs chosen for the pillars and arch supports, but I do not think the inclusive cost of the lamp wires, lamps, pillars, and arch supports will exceed £5,200." The Electric Committee, of which Councillor Stafford is chairman, announce that they have carefully considered the proposals contained in the above report, and recommend the same to the Council for adoption. To enable the scheme to be carried out, it is necessary that the contract with the gas company of June 9, 1893, for lighting the Marine-parade, should be determined as from June 24, 1895, and that the contract with the gas company of October 31, 1890 for the lighting of the remaining street lamps in the borough should be determined as from the same date, so far as regards the lamps in the streets named in the above report, and the committee recommend that notices be given to the gas company determining such contracts. The committee further recommend that application be made to the Local Government Board for sanction to borrow, under the powers of the Public Health Act, 1875, the sum of £5,200 for a period of 25 years, to defray the cost of the new lamp columns, lamps, supports, and appliances.

Dewsbury.—The report of the Gas and Lighting Committee stated that an order for six arc lamps and pillars was given to Messrs. Crompton and Co., London, at £23 per lamp, to be ready for lighting on December 21. The following appointments were made for the electric lighting station: J. H. Windham, Cheltenham, dynamo attendant, £1; S. Mitchell, Bradford, jointer, £1. 15s.; D. H. Chadwick, Dewsbury, engineer, £1. 18s.; Thos. Newsome, Dewsbury, stoker, £1. 4s.; Jabez Auty, Dewsbury, joiner, £1. 10s.; Jackson Best, Dewsbury, clerk, £1. 6s.; C. M. Shaw, Dewsbury, office boy. 8s. It was agreed to extend the electric lighting mains to Union and Grove streets. A fresh dynamo for the sulphate plant works was obtained. The electric arc lamps were ordered to be erected in the Market-place, Lower Westgate, and at the end of Church-street. A further extension of the electric mains was ordered for Bradford-road. Alderman Robinson moved, and Councillor Archer seconded, the confirmation of the minutes. Alderman Fox referred to the recommendation of appointments in connection with the electric lighting station, and said that in his opinion they might have done with a less staff He asked if the different installations put into the shops by private consumers had been properly tested and certified by the engineer before the works were opened, and said the arc lamps should be so arranged in the streets that they would not be called upon almost immediately to erect a half-dozen more lamps Alderman Robinson said they asked Mr. Mitchell to report only as to the men he would actually require, and a sub-committee was appointed to go through some 60 applications. He could assure the Council that the committee would not keep an unnecessarily large staff. With regard to a question put by Councillor Vero as to the £318 for an extension of the main in Bradford-road, it was to supply people who had applied for electric light. The committee did not sanction the expenditure of £228 in Bond-street, as they considered the outlay much too great for the revenue at present. He entered into a long explanation regarding the instructions given to the engineer to see that everything was perfectly secure and in order and under proper supervision before the electric current was switched into the distributing mains. Alderman Fox moved an amendment that the minutes be confirmed, with the exception of the resolution referring to the appointment of workmen at the central electric station, and that this matter be referred back for further consideration. In addition to the salaries of Mr. Mitchell and Mr. Pickersgill, the total amount recommended for wages was £468 per annum. Councillor Vero seconded the amendment. Councillor Archer said it would be better for Alderman Fox to make some suggestion, to tell them where the committee had done wrong, or where they could improve upon their action. Seven voted for the amendment and seven for the motion, and the Mayor gave his casting vote in favour of the former.

Devonport.—The Streets and Highways Committee of the Borough Council reported that, having carefully considered the application of the County of London and Brush Provincial Electric Light Company, Limited, for the consent of the local authority to the application of the company to the Board of Trade for the grant of a provisional order for the supply of electric lighting in the borough, they were of opinion that it was not advisable at present that the local authority should give such consent, and that the company be so informed. Mr. Graves moved the adoption of the report. Mr. Oram, in seconding, said the feeling of the committee was that the power should be kept in the hands of the Council. The company had received no encouragement from the committee to take proceedings, but it had been clearly intimated to them that whatever action they took was on their own responsibility. Mr. Rendle expressed surprise that Mr. Graves had not explained why the committee opposed such an important question as the introduction of the electric light in Devonport. He took it, from what Mr. Oram had said, that the committee intended to oppose! The Town Clerk said no independent company or outsider could apply for this provisional order without the consent of the local authority, and therefore unless such consent was given there was no chance whatever of the application succeeding. Mr. Rendle, continuing, asked what chance there was of the Council applying for a provisional order to supply the town with electricity themselves, or to lease it to a company while the Streets Committee was constituted as at present. There was not enough go in the Council. He knew to what extent they suffered at present from impure gas, and was almost tempted to ask why they had not appointed a gas inspector, because the quality of the gas of late had been something fearful. He did not think the committee had been just to the company which had intimated its intention to apply for electric lighting powers, and seeing that they were not all gas company shareholders or directors, they should consider, in their representative capacity, the requirements of the town. He moved that the recommendation be referred back. Mr. Hornbrook seconded, and said it should not go forth

Digitized by Google

that they were against the principle of electric lighting. They could not afford to stand before the public in that sense, and it would be unjust and impolitic if they did anything that would lead the public to suppose they were opposed to the electric light. There were, perhaps, too many gas company shareholders in the Council, and some of them not members of the committee whose recommendation was under consideration. The question ought to be considered by a committee none of whom had the slightest interest in the gas company. Mr. Tozer said as members of the Corporation they should set aside all personal interest. Mr. J. May thought electricity had not sufficiently advanced to justify them in permitting its adoption for street-lighting. The Mayor suggested that Mr. Rendle should withdraw his amendment, and this having been done, the committee's recommendation was agreed to.

Yarmouth.—The borough surveyor to the Town Council produced a plan he had prepared showing the positions of the arc lights necessary for lighting St. Peter's-road, and stated the cost would be £100. The annual cost would be £48. The cost of the 10 gas lamps now on the district which would be turned out was £33. 15s. The annual additional cost of lighting road by electricity over gas, including capital and interest charges, would be £14. 5s. The committee resolved to recommend the Council not to carry out the work at present until a more general scheme of extension became necessary. Mr. J. H. Palmer said he thought as the cost was so small as compared with that of the gas lamps, it ought to be carried out on the Jetty-road. The residents in the district were very anxious to have the light there. There was a strong feeling in favour of it, and he did not see why it could not be done at once. He moved that it be carried out before next summer. Mr. A. Peaton seconded. He found, on enquiring, that the residents on St. Peter's-road were very much in favour of the electric light being laid on instead of the gas lamps, and he hoped to see it carried out. Mr. W. Worlledde said it was very evident from the remarks made that if they were to put the light on St. Peter's-road, all the other roads in the town would want it too. In course of time every road in the town would be lighted; but he considered they ought to feel their way, and not embark upon a scheme which would be sure to cause unpleasantness in other parts of the town. He thought, therefore, it would be best to abide by the decision of the committee. Mr. Press objected to spending any more money just yet upon the extension of the light. It would not do to go ahead too fast. It was strange that they were so impatient, seeing that they had been content with the gas so long; they must move on by degrees, and in time all would have the light. Mr. Martins said it would be very unwise to do more at present; as the work increased and the light was extended a larger sum of money would have to be borrowed to carry it out. Mr. Palmer's amendment was then put, and lost by 4 to 18. Replying to the remonstrances of the town clerk, Messrs. Crompton and Co. wrote stating that they were sparing no efforts to complete the electric light contract, and that various portions of the plant would shortly be delivered. Mr. W. H. Preece, the Council's electrical adviser, wrote that the floods in the Thames Valley had delayed the testing of the dynamos. The Local Government Board wrote sanctioning a further loan of £1,500 for the purpose of electric lighting. The present screens on the parade lamps being considered insufficient to meet the requirements of the Trinity Board, the surveyor was directed to confer with Mr. Thorp. To reach three customers, it was decided to lay mains at a cost of £36, though the surveyor said that this would represent the first year's income from the trio. He also reported five applications for 205 lamps. The managing engineer recommended the use of Clifton coal at 14s. 3d. per ton, and the surveyor stated that he expected the consumption, when the plant was in full working order, would be 20 tons per week.

Bath.—Mr. Cedric Chivers asked at a meeting of the Surveying Committee of the Town Council what position they were in with regard to the application made to the Board of Trade by the electric light company to extend their powers. The company had applied for a provisional order, and he wished to know whether there was any proposal to take a vote in the Council and establish their intention to buy up the works and carry on the lighting themselves; if not, the company were in a very strong position. The Chairman said the Urban Authority had already decided to oppose the application. Alderman Sturges said the matter had not been overlooked or forgotten by the Lighting Committee, who had discussed it at several meetings. They had sent a set of questions to the electric light company for them to answer. The company had delayed answering for an undue time, but as soon as they got their written answers the committee would be in a position to recommend to the Council what they thought in their wisdom was best to be done. As soon as they got the necessary data to go upon they would be able to send up a recommendation either to oppose, to buy, or to make an application. Mr. Taylor was afraid there was considerable reason for Mr. Chivers asking the question, and that the Lighting Committee had not gone far enough. If they appeared to be lax in this matter they would suffer in consequence. They knew Mr. Pitman and Mr. Titley very well, and if their action was subject entirely to their replies to certain questions they could delay these answers just as long as suited their purpose, and they might delay them long enough to injure the Authority's position. He proposed that Alderman Sturges, the chairman, and the clerk be instructed to convene a special meeting of the Lighting Committee. Alderman Sturges thought Mr. Taylor was unnecessarily frightened. The Chairman said the memorial would not be presented until the 21st of the present month. Mr. Moore strongly agreed with Mr. Chivers that prompt action should be taken. It was of no use to oppose unless they could show that they were going to do something. Mr. Chivers: That is the point. The Chairman, after further discussion, said he believed the matter would come before the Authority next week, and he believed that Mr. Titley was to be there, so that up to then at all events there could be no time lost. Mr. Chivers could not agree that no time had been lost. When the company made their application they also should have filed their opposition to it. The Clerk said no time had been lost. Alderman Marshall thought the company should be pressed for an answer. The Chairman said they could not put in any counter application; the application of the electric light company must be treated on its merits. Mr. Chivers said he understood that in all such cases where corporations had not sent in a counter application the provisional order had been granted, and *vice versâ*. After further discussion, Alderman Sturges said he hoped they would be able to recommend to the Authority next week what course to adopt. They would urge the solicitor of the company to send the answers, and a special meeting of the committee would be called as soon as they were received. The subject then dropped. Mr. E. B. Titley has since written stating that there had been no delay. He explained that the draft provisional order had to be revised, and the replies to the Authority's questions settled at a special meeting of the board of directors to be held in London. These replies would be in the hands of the clerk to the Authority by the end of the week. The Surveying Committee agreed, on the motion of Mr. Knight, to remit the fines which would otherwise have been due from the electric light company for lamps out during the flood.

Ulverston.—The clerk to the Rural Sanitary Authority read the minutes of a meeting of the Electical Lighting Sub-Committee held on the 21st ult, at which a letter was read from Mr. Sydney Morse, stating that the terms upon which the Windermere and District Electricity Supply Company would vary the purchase clauses of the Electric Lighting Company, 1888, in favour of the local authorities. Messrs. Savory, Fewkes, and Morse had met the committee for the purpose of explaining and arranging the terms as offered in Mr. Morse's letter. After considerable discussion, the committee decided to ask the representatives of the company to make, formally in writing, offers to each of the authorities of the terms which they were prepared to agree with the authorities for the supply of electrical energy, and the committee recommended that the new district councils be advised to appoint committees at the earliest possible moment to receive and consider these terms. The committee recognised the importance of the negotiations, and regretted that the change in the constitution of the authorities would much increase the difficulties of dealing with the matter which must be settled before the meeting of Parliament, or action must be taken by the district councils to safeguard their interests before the Board of Trade. Mr. Hodgson, the chairman of the committee, said that he had come there specially that afternoon to move the adoption of the report There was no doubt this was not only one of the first, but one of the most important questions the new District Council would have to take up and deal with. The company in question aimed at getting a provisional order which would give them power to supply electrical energy and light over the whole of the present Rural Sanitary Authority's district, and it would be necessary for the different public bodies interested to watch their proceedings very carefully, for, although the negotiations seemed up to a certain point to proceed satisfactorily, he was sorry to say he was afraid, from the correspondence since received, that the terms would not be so easily arranged as they had thought they would be. Probably the company thought the local governing bodies were just now in such a state of transition that they might be able to get their provisional order without any trouble, and it behoved the new Council to take the earliest steps to closely watch, and, if necessary, protect the interests of the public. Of course, if the worst came to the worst through their being unable to get reasonable terms, then opposition would have to be taken, and they would have to go before the Board of Trade and prove their case. There was no doubt a great future for electricity and its development for lighting and other purposes, and that any single company should be allowed to get a practical monopoly in regard to electric lighting over the whole district was certainly not fair or reasonable, or conducive to the public interests, and he did not think the new Council would allow it unless they got such terms as they were trying to get the company to agree to. It was not right that these terms should be made fully public at present, but he might say the basis of what they asked for was that if the company was allowed to come into the district the Authority should have the power to take over at any time the works and mains and distributing arrangements on terms reasonable for all parties, and that those terms should be precisely fixed before the company obtained its provisional order. That was the crux of the whole question, and he hoped the new Council would elect a committee as soon as possible to try and get these terms. They did not want to oppose the company for the sake of opposing it, but they felt they should look well after their own rights and interests, and not allow any company because it was a little sharper than its neighbours, to get hold of a perpetual monopoly of a thing which might be of the greatest value and importance to the community in the future. Mr. Dove seconded the motion, and the report was unanimously agreed to.

Taunton.—The Electric Light Committee of the Town Council presented the following report: "A letter has been received from Mr. A. E. Witham resigning his appointment as clerk and collector, in connection with the electric lighting works, on January 31 next. Your committee report that Messrs. Shand and Thornhill (assistant electricians) have asked for an increase in their salaries. The committee recommend that Mr. Thornhill be

Digitized by Google

raised to £75 and Mr. Shand at £65 a year, as they have been offered other situations at larger salaries. Your committee report that the estimated cost of the cables and making the necessary house connections in connection with the No. 2 sub-station is £681, and the committee recommend the Council to authorise them to order the same from the Fowler-Waring Cables Company directly the sanction of the Local Government Board to the borrowing of the money has been received." Councillor Potter moved the adoption of the foregoing report. As regards Mr. Witham's resignation, Mr. Potter said he was personally indebted to him for much valuable assistance, and would be sorry to lose his services. The committee hoped to get all the wires put underground by the time the Bath and West of England Society visited Taunton, and they would carry out the work as soon as the sanction of the Local Government Board was obtained to the loan and subject to the sanction of the Council. Mr. Potter also broached the subject of discounts on electric lighting accounts, and said it was suggested that when 4,000 units were used by a customer in a year, which would cost him £100, they should charge 5d. instead of 6d. per unit. Speaking of the complaints which had recently been made respecting the unsatisfactory nature of the electric light, the speaker said it was well to know that it was not due to negligence on the part of anyone, but simply the result of an unfortunate series of circumstances, and those circumstances he proceeded to explain very satisfactorily. Alderman Standfast spoke against the proposed increase of salaries, but Councillor Perkins expressed himself in favour of the proposal, stating as his reason that they could not expect young men of education and considerable technical knowledge to undertake duties of a responsible and even dangerous character for a lower salary than they could get elsewhere. Councillor Nation said there was an impression alive that they had a lot of juveniles at the work, and some people were deterred from taking in the light on that account. Councillor Sibley said they were not overmanned at the works, as Alderman Standfast seemed to suppose, but quite the reverse, and Councillor Potter supported the statement in his reply. Councillor Potter, in replying to the criticisms on the actions of the committee, said the arguments that had been advanced were out of all reason. With regard to the reduction of the staff, it was perfectly ridiculous to talk of doing so. The plant was running 19 hours on a stretch, and there was no one employed on the works who did not work eight hours a day, including Sundays, and he contended that the only fault in the management of the works was that they had been too economical, and had suffered in consequence. If they dismissed the present staff and took on older men, they would have to pay much larger salaries. The mistake they had made was that they had not sufficient on their staff. They should understand that these young men were not placed in charge of the works, and in reference to the young man that met with the accident he would remind them he was not in charge. Mr. Couzens could not always be there, and the second electrician was in charge at that time. The young man was doing work that he had done some hundreds of times, and if he had done it with safety ninety-nine times he might with the same care have done it the hundredth time. An amendment which had been moved by Councillor Westlake, to refer the question of salaries back to the committee, was lost by eight to nine.

Southampton.—The town clerk, at a meeting of the Town Council, read the following letter from Messrs. Sharp, Harrison, Turner, and Turner, on behalf of the electric light company: "Dear Sir,—We are instructed by the Southampton Electric Light and Power Company, Limited, to apply to the Southampton Town Council, as the local authority specified in the Electric Lighting Acts, 1882 and 1888, for their consent to a provisional order, now being promoted by the company under the said Act, for authorising them to supply electrical energy for public and private purposes throughout the county borough of Southampton. In making this application we would remind you that, under Section 1 of the Act of 1888, the granting of a provisional order to our clients will not in any way hinder or restrict the granting of a similar order to the local authority if they decide to apply for one. Our clients desire us to state that, should the Southampton Corporation decide within six months from this date to negotiate for the purchase of their undertaking, they would be willing to sell at a fair price, and agree not to include in it any additional value by reason of the consent now asked for being given. In acquiring the provisional order to be obtained by our clients, the Corporation would gain the advantage of securing an order a year sooner than they otherwise could. Our clients trust it will be taken into account that they have in every way fulfilled the obligation under the license they now hold, and have given general satisfaction to the public, and that their undertaking has been promoted by the local enterprise which should entitle their present application to receive the most favourable consideration." Mr. Lemon said it would be in the recollection of the Council, when this matter first came up he proposed that the Council should purchase the powers obtained by the company, but the Corporation in their wisdom, or, perhaps, unwisdom, did not see their way to do so. Since that time the company had been giving a supply of electric energy to the town, and now asked that the consent of the Corporation should be given to their obtaining a provisional order. He had had the opportunity of discussing the matter with his colleagues on the Works Committee, and was able to speak on their behalf to this extent—they advised the Council not to oppose the provisional order. It was quite open for the Corporation to claim the provisional order for themselves, but they would be in this position—they would have to compete against an existing company, and when they considered the result would be filling up the streets with two lines of wires, pulling up footways, and also the remote chance of getting back a return of the capital expended, the Corporation would be very unwise to enter into a competition of that kind. It would be noticed in the letter that the company said they were willing to sell at a fair price, and did not wish any additional value by reason of the consent being given taken into account. He thought the time had come when they should purchase these works if they could do so at a reasonable price. He had had an opportunity of looking into the matter, and he was able to say that they could purchase them at a very reasonable sum indeed. The only question they had to consider was one—they should be advised by an expert as to whether the money laid out by the company had been properly expended, and would the Corporation, if they started the works in the first instance, have laid out the money to better advantage? He would say from his knowledge that they could not have done so. He proposed that they should not oppose the granting of the provisional order. Alderman Bance seconded the proposition. The Town Clerk, in reply to questions which were raised, said the matter had been referred to committee, and they had the matter under consideration, but the question of this provisional order must be dealt with by the full Council. They could give or refuse their consent, but if they refused it would be for Parliament to say whether it was a reasonable refusal, and if they thought not they would take no notice of it. If they consented, the company would get the order as a matter of course. If they withheld their consent, they would have to give some excuse such as that they were going to apply for a provisional order for themselves, and they would have to go to some expense to be successful in their opposition. After a long discussion the motion was agreed to.

Windsor.—An item on the agenda of the Town Council was as follows: "Mr. Alderman Dyson to ask for the Electric Lighting Committee minutes of July 4 and September 13, and to make a statement thereon." In again introducing the matter, Alderman Dyson made a long speech, in which he complained of the hard words used towards him on a previous occasion. On September 13 he considered that Mr. Shoolbred had been invited to Windsor without a resolution having been passed by the committee to that effect. If he were wrong he would withdraw and apologise, but he did not withdraw one word. He asked for the production of the minutes. Mr. Lovegrove said that a motion of the Council must first be passed. Councillor Bampfylde said that if Alderman Dyson really wished to see the minutes he would move that they be produced. Councillor Soundy seconded. This was passed. Mr. Lovegrove then read the minutes of July 4, in the course of which appeared a resolution to the effect that Mr. Shoolbred be written to to ask upon what terms he would come to Windsor and report. Alderman Dyson said that was the whole of his complaint. No authority had been given to invite Mr. Shoolbred down here. This he emphasised in some lengthy remarks. Councillor Withnall asked that the minutes of September 5 be read also. Mr. Lovegrove did so, and in those minutes appeared a resolution approving of the action of the chairman in inviting Mr. Shoolbred to attend, and also authorising his engagement to come down and make a report. Alderman Dyson, reading from a newspaper report, said that on October 4 the deputy town clerk, in reading the minutes of July 4, had said that the resolution was to the effect that Mr. Shoolbred be written to asking him to come to Windsor and make a report. In conclusion, he assured them he had no intention of attacking any committee. Mr. Lovegrove said that Mr. Dyson had said many things in his speech which, if he (Mr. Lovegrove) were a member of the Town Council, he should be able to controvert and confute, but being the representative of the town clerk he was not able to enter into any argument with him. The attack which Alderman Dyson made was made upon him, but he stated emphatically that in all he had done he had acted under the direct and explicit instructions of the committee. He was not responsible for what appeared in the paper. He read the resolution from the book at the time, and he was sorry if Alderman Dyson relied upon the report in the paper. He repeated that he had received the instructions of the committee for everything he had done. Alderman Dewe confirmed this, and said that all Mr. Lovegrove had done had been by the direct instructions of the committee. In reply to advertisements they had 49 answers, and at the meeting on July 4 Mr. Shoolbred was chosen therefrom, and it was resolved to write for his terms, and if under 30 guineas he (Alderman Dewe) was authorised to write to Mr. Shoolbred to come down and meet the committee. It was arranged that he be invited on September 13, and he was admitted on that date and engaged with the full sanction of the committee. What Mr. Alderman Dyson had to stand upon he did not know. He seemed to presume that he and the deputy town clerk had invited Mr. Shoolbred down without authority. That was not so, and if Mr. Dyson had been at that meeting of the committee he would know it. Alderman Sir Joseph Devereux said he should be sorry to think that Alderman Dyson had made an attack upon the deputy town clerk, upon whom he seemed to lay all the charge. He made an ample apology on the occasion when the matter was last brought up, and he (the speaker) was sorry the matter had been brought forward again. He considered it to be a waste of their time, and he moved that the meeting proceed to the next business. Councillor Gane seconded, and fully supported all that Sir Joseph Devereux had said. Councillor Soundy said that he thought the wiser course would be to allow the matter to be thrashed out. He did not like the idea that any member's mouth should be closed. Alderman Dyson again returned to the attack. He said he had stated most solemnly that a personal attack was very far from his mind. He then proceeded to go all through the case again with respect to the resolution of July 4. Mr. Lovegrove again warmly repudiated the newspaper report of the minutes which were read at the meeting of October 10. He said that if

Digitized by Google

the words "for terms" were left out by the reporter, he (Mr. Lovegrove) was not responsible. Councillor Bampfylde said that the very point had been argued out in committee. He thought that Alderman Dyson was going to keep to the point whether the minutes had been correctly read or not. Mr. Lovegrove had denied that the newspaper was a correct report of what he read, and Alderman Dyson should receive and accept that. He (Alderman Dyson) had appealed for the treatment of a gentleman, and he considered he should accord the same treatment. Councillor Burt said he felt bound to justify the conduct of Mr. Lovegrove. It was most distinctly understood when Mr. Shoolbred was written to that if his terms were reasonable he was to be asked to come down. Alderman Sir Joseph Devereux withdrew his motion by request, and Alderman Dewe moved "That this Council having heard Mr. Lovegrove's statement accepts the same." This was seconded and carried *nem. con.*, and the incident then closed, after occupying nearly an hour.

PROVISIONAL PATENTS, 1894.

DECEMBER 10.

23970. **Improvements in electric conductor supports.** Albert Anderson and John Marinius Anderson, 62, St. Vincent-street, Glasgow. (Complete specification.)

23980. **Improvements in sentinel electrical alarms.** Antoine Moise Morin, 76, Finsbury-pavement, London.

23988. **Improvements in electric lighting devices.** Robert Walker Inman, 55. Chancery-lane, London.

24002. **Improvements in the manufacture of armatures for electric bells.** Isaac Hardy Parsons, 4, South-street, Finsbury, London.

DECEMBER 11.

24075. **Improvements in regulating electric dynamos and motors.** Thomas Drake Hollick and Frederick William Hollick, 604, Commercial-road, London.

24076. **Improvements in and relating to telegraphic transmitting and receiving apparatus.** Bernard Hoffmann, 55, Chancery-lane, London.

DECEMBER 12.

24173. **Improvements in and relating to electric motors and to the distribution of electric energy.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Hermann Gutmann, Germany.)

24194. **Multiple electric fuse-box.** Edward Avery Parson and Haldane Millar, Philadelphia, U.S.A.

24195. **A mode of controlling magnetic energy.** Henry Monroe Paine and Albert Russell Brandly, Philadelphia, U.S.A. (Complete specification.)

24198. **Improvements in electrical resistances and in processes for rendering inert or electrically non-conductive substances electrically conductive.** Augustus John Marquand, Emmanuel Hancock, and David Lowdon, 24, Southampton-buildings, Chancery-lane, London.

DECEMBER 13.

24234. **Reflectors for electric lighting.** Paul Körber, 62, St. Vincent-street, Glasgow. (Complete specification.)

24266. **Improvements in apparatus for starting alternating-current electromotors.** Arthur Bergtheil and Robert Alfred Marples, 1, Queen Victoria-street, London.

24285. **Improvements in and connected with electric systems for lighting of trains and for other purposes.** Anthony George New and Arthur James Mayne, 55, Chancery-lane, London.

24291. **Improved means for securing the terminal wires to carbon and other electrodes.** Franz August von Alimonda and Nino von Alimonda, 11, Southampton-buildings, Chancery-lane, London.

DECEMBER 14.

24297. **An improved porous cell for an electric generator or battery.** William McChleary, 154, St. Vincent-street, Glasgow.

24340. **The electrical nail detector or finder for prevention of crippling of animals caused by deviation of shoe nails.** Frederick Jones, 76, Wakehurst-road, Clapham Junction, London.

24353. **Improvements in brackets for poles or standards for electrical conductors and similar purposes.** Siemens Bros. and Co., Limited, and George William Perry, 28, Southampton-buildings, Chancery-lane, London.

24369. **Improvements in or appertaining to electric bells or alarms.** John Thomas Brierley, 6, Lord-street, Liverpool.

24372. **Improvements in shade-holders for gas, electric, and other lamps.** Sigmund Sinauer, of the firm of S. Hoffnung and Co., 191, Fleet-street, London. (The Utility Shade Company, United States.)

24374. **Improvements in the insulation of electric wires or cables.** Franz Clouth, 18, Buckingham-street, Strand, London. (Complete specification.)

DECEMBER 15.

24385. **Improvements in electric supply meters.** John Perry, 31, Brunswick-square, London.

24431. **An improvement in tubular posts for telegraphic and other purposes.** Siemens Bros. and Co., Limited, and George William Perry, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

24440. **Improvements in devices for joining or connecting telegraph and telephone wires, and for other purposes.** William Broomhead Shaw, 6, Lord-street, Liverpool.

24441. **Method and apparatus for preventing sparks in electrical apparatus.** Wilhelm Friedrich Ostwald, 433, Strand, London.

SPECIFICATIONS PUBLISHED.

1888.

2246. **Dynamo-electric machines.** Lake. (Eickemeyer.) (Second edition.)

1890.

9361. **Electric reduction of metals.** Willson. (Second edition.

1893.

18173. **Electrolysis of chlorides, etc.** Hargreaves and Bird. (Second edition).

22674. **Electric batteries.** Haddan. (Riguelle.)

23231. **Micro-telephones.** Anders and Kottgen.

23472. **Electrical measuring instruments.** Nalder and others.

24471. **Electric supply meters** Baron Kelvin.

1894.

294. **Type printing telegraphic apparatus.** Thompson. (Kustermann.)

439. **Girder clamps and hangers for supporting pipes, electric conductors, etc.** Lake. (MacTaggart and another.)

1433. **Advertising by electric lamps.** King.

2487. **Secondary batteries.** Hall.

3859. **Electric gas-lighting apparatus.** Thompson. (Ulmer.)

12877. **Electrically controlling steam machinery, etc.** Lake. (Williamson.)

13358. **Electrolysis.** Lake. (Roberts.)

16851. **Electric railways.** Thompson. (Enholm.)

18522. **Electric arc lamps.** Pendleton.

NOTES.

Calendar. — The Electrical Installation Company, Limited, of 66, Victoria-street, S.W., and of Edinburgh, send us a neat little pocket calendar.

Electric Light in Japan.—According to a French contemporary, there are 11 electric lighting companies in Japan, with a total capital of £487,200.

Brush Company's Diary.—The Brush Electrical Engineering Company, Limited, have sent us a handy diary for 1895 suitable for carrying in the vest pocket.

Paper-Knife Almanack.—The Eastern Telegraph Company have sent us a paper-knife which indicates the routes followed by their cables and also gives an almanack for 1895.

Central London Railway.—It was mentioned at a meeting of the Exploration Company last Friday that the company hope next year to make a successful issue of the capital of the Central London Railway.

The Theatrophone.—An illustrated description of the theatrophone is given in the *Revue Industrielle* of the 22nd December. The offices of the company working this system in Paris are at 23, Rue Louis-le-Grand.

Electric Bells and Medical Coils.—A trade list has reached us of the specialities made by Messrs. Howard B. Little and Co., of 20, Eldon-road, Kensington, W. Among these are the "ringing" bells, portable bell sets, and medical coils.

The Proposed Jungfrau Railway.—The Swiss Federal Council on Friday agreed to the Jungfrau Railway scheme on condition that the company contributes £4,000 to the construction of the observatory, as well as monthly subscriptions to certain scientific societies.

Telephony in France.—Telephonic communication has been established between Paris and Toulouse *viâ* Limoges. By March next connections will be made between Toulon and Bordeaux *viâ* Montauban and Agen, and between Toulouse and Cette *viâ* Carcasonne, Narbonne, and Béziers.

Electric Traction in Switzerland.—The Government have given authority to the Zurich Mountain Railway Company for the construction of three lines of electric tramway.—Powers have been given for the construction of an electric tramway between Bruggen, St. Gall, Neudorf, and St. Fiden, with a branch between St. Gall and Heiligkreuz.

Presentation.—A smoking concert promoted by the staff of the Electric Construction Company, Limited, took place last week at Wolverhampton, when Mr. R. Johnston, chief of the office staff, who was to be married on Christmas Day, was presented with a marble clock from his fellow employés, a purse of gold from the directors, and a gold ring from several friends.

French Colonial Telegraphs.—Considerable progress is being made with the length of telegraph line between Grand Bassam and Hou, which is situated at the mouth of the River Bandama. A distance of 140 kilometres has been completed. Only another 20 kilometres remains to be done, and the work will be finished as soon as a fresh stock of wire arrives.

Telephony in Spain.—The lines between Madrid and Barcelona and Bilbao and Vittoria, it appears, are only a portion of a projected network of telephone lines. According to *Industria é Invenciones*, Mr. Los Arcos has obtained a concession for the erection and working of telephone lines between Barcelona, Sarragossa, Bilbao, and Madrid, and various towns in the north-east of Spain.

Personal.—Prof. Kohlrausch has been appointed head of the Physical-Technical Governmental Institute at Charlottenburg.—Sir David Salomons has, as Mayor of Tunbridge Wells, issued invitations for the mayor's banquet, which will be held in the Great Hall, Tunbridge Wells, on Saturday, January 12.

Liverpool Engineering Society.—The president, Prof. H. S. Hele-Shaw, M.I.C.E., presided last week over a meeting of this society at the Royal Institution, Colquitt-street, when Prof. Oliver J. Lodge, D.Sc., F.R.S., read a paper entitled "The Second Law of Thermo-Dynamics." The paper was listened to with great attention, as well as the remarks of Prof. FitzGerald in the discussion which ensued.

The Telautograph.—A Paris correspondent states that the Société Internationale des Electriciens have held a special meeting to examine the Gray telautograph introduced by Mr. John Aylmer, the telegraph agent of the British Government in Paris, and Mr. Cushing, of Chicago, the representative of Mr. Gray, the inventor. The instrument has been submitted to the French Government, and has been experimented with in an exhaustive manner, even between London and Paris.

Electromotors on Men-of-War.—In connection with our "Note" on this subject in our last issue, it is interesting to observe that the United States Naval Ordnance Bureau has invited a number of electrical firms to submit designs of electrical apparatus for the operation of turrets and guns. Electricity has been used for the operation of the "Montauk's" turrets for some time, and the experiments have resulted very satisfactorily. It is intended to place electrical apparatus in the turrets of the "Brooklyn" and "Iowa."

Electric Traction in France.—The Lyons Tramway and Omnibus Company have sent to the Municipal Council a scheme for adopting electric traction on the whole of their system. An enquiry has also been held into a proposal to construct an electric line from Lyons-Vaise to Saint-Cyr-au-Mont-d'Or. This is brought forward by the Ecully Tramway Company. Negotiations are also in progress between this company and the communes of Dardilly, Champagne-au-Mont-d'Or, and Limonest for the construction of electrical tramways. These districts are very badly served at present in the matter of traffic facilities.—Mr. Stulzmann, a Swiss electrician, proposes to construct an electric tramway between Gex and Ferney, Ain.

Light and Heat Exhibition.—Under this title, an exhibition which promises to be of more than ordinary interest, from a general as well as a domestic point of view, is to be opened in May, 1895, at Woodhouse Park, Shepherd's Bush. The site, which is in close proximity to the Uxbridge-road railway station, is an exceptionally good one. The exhibition will be one of a complete and instructive character, in which all means of lighting and heating—civil, naval, and military—will be thoroughly illustrated, whilst photography in all its developments will be well represented, and a historical gallery will furnish examples of lighting from the earliest ages up to the present time. The profits will be devoted to the Sunday Hospital Fund.

Electric Traction in Germany.—The large project for a network of electric tramways for the Bochum district, with which a commencement has been made with the Bochum-Herne line, appears likely to be carried out at no distant date. Definite arrangements have been made for constructing the Herne-Recklinghausen line, and now the sanction of the Government has been obtained for a line

Digitized by Google

between Gelsenkirchen, Waune, and Eickel. From this last connection will be made with Bochum. This will be the largest system of electric tramways in Germany.—It is expected that arrangements will shortly be concluded for the conversion into electric lines of the Dantzic horse tramways.—The Municipality of Barmen have decided to build an electric tramway between Barmen and Schwelm.

Telegraph Rates to Egypt.—A memorial, signed by 62 Liverpool merchants in trade with Alexandria, asking for a reduction in the charge for telegrams to Alexandria, was recently forwarded to the Eastern Telegraph Company with a request that the representation should be considered and concessions made to meet the views of the memorialists. The rate to Alexandria is 1s. 7d. per word, whilst the rate to Malta is only 6d. per word, and to Syrian ports 6½d. per word. Sir John Pender has replied that at the present time the company's dividends are not such as to warrant reductions, but that the matter will be borne in mind and discussed at the international telegraph conference to be held in 1896, as any reduction that might be made would apply to correspondence with Europe as well as Great Britain.

Crypto Electric Motors.—Small dynamos and electric motors are being made on a large scale by the Crypto Works Company, Limited, of 29, Clerkenwell-road, E.C., a copy of whose catalogue has reached us. The S type of motor is combined with a ventilating fan for use both on board ship and land. This motor is intended for working either with direct or alternating current. Another arrangement, which comprises a C motor and rotator equipped with five coloured chain lamps, is a useful lighting device for placing in shop windows, so as to attract the attention of passers-by. A variety of small motors and dynamos for lecture purposes is also detailed in the catalogue, which concludes with references to a hand-feed focussing arc lamp for the lighting of theatrical stages in place of limelight, and for experimental use.

Electric Welding Patents.—The action brought by the Thomson Electric Welding Company, of Lynn, Massachusetts, against the Two Rivers Manufacturing Company, of Wisconsin, has resulted in a decree sustaining the validity of the fundamental patents of Prof. Elihu Thomson on electric welding and apparatus therefor, and adjudging that the defendants have infringed them. A preliminary injunction was granted several weeks ago against the Two Rivers Manufacturing Company by Judge Siemens, who rendered an opinion sustaining these patents. The case was tried on behalf of the defendants, and all known defences were before the Court. The judge found, however, that the patents were valid, and that they were not affected by any of these defences, and therefore an injunction was granted.

Lecture.—Mr. H. A. Mavor has read before a meeting of the Institution of Engineers and Shipbuilders in Scotland, held in Glasgow, a paper on "A New Mining Motor." He referred to the application of electricity to mining operations, and afterwards gave a detailed description of the new motor. The distinctive features of the motor were that it was entirely enclosed in a cast-steel casing, was very light, and of specially strong mechanical construction. He described the principles of an electric motor, pointing out that these might be most easily understood by looking at magnetism and electricity as two aspects of the same phenomenon, magnetism being a whirling motion in the medium surrounding the electric current. By the study of these whirls the interaction of electric currents and magnets might be more easily understood than in any other way. He remarked that the possibility of making a light enclosed mining motor had been reached largely through the use of a new material which, although it was called steel, was merely chemically pure iron obtained by a steel process.

People's Palace Day Technical School.—The annual distribution of prizes and certificates to the pupils took place in the Queen's Hall on Friday. Prof. Alexander Kennedy, F.R.S., was the distributor, and Mr. W. Hales, master of the Drapers' Company, presided. Prof. Kennedy said that he wished to add his testimony to the good work which the school had done. He had seen many drawings done by the pupils and much of their practical work, and he had been very much pleased with them. They showed him that the line taken in that school, and the general course adopted, were the best suited to prepare lads for apprenticeship to the engineering trade. He considered it most important that the engineers of the future should not only be apprentices, but educated apprentices. Such work as that school was doing should, he thought, be encouraged by the great trade unions, whose status would be considerably raised if they insisted on the proper training of their future members.

Storage Battery Amalgamation.—Our American contemporaries announce that all the fundamental storage battery patents have been acquired by the Electric Storage Battery Company, the owner of the chloride battery patents. The Faure group of patents (including those of Swan, Sellon, Volckmar, and Griscom) were acquired from the Accumulator Company, the Brush-Julien patents from the Consolidated Electric Storage Company, and the Brush patents from the General Electric Company. This terminates the litigation in which the various companies had become involved, and the Electric Storage Battery Company will now be the sole manufacturer of storage batteries under the patents acquired. No official statement has as yet been made in regard to the future relations with the companies from whom the various patents were purchased, but it is reported that there will be a friendly co-operation. The Electro-Dynamic Company, which has always been closely connected with the Accumulator Company, will continue to manufacture dynamos and appliances for storage battery plants, and it is reported that the General Electric Company will exert its influence in favour of the interest now in possession of the patents.

Municipalisation of Tramways.—The Bill which will be promoted by the London County Council next session for powers to enable it to work tramways has been finally drafted. The preamble recites that under powers granted by Parliament the Council has purchased a portion of the undertaking of the London Street Tramways Company, and is proceeding to acquire others. It is, therefore, expedient that powers should be given for working the tramways when secured. Clause 2 enacts that it shall be lawful for the Council to place and run carriages on any tramway which has been, or shall be, purchased or acquired by them, and to provide such stables, buildings, horses, cars, engines, fixed and movable plant, etc., and to employ such persons as may be requisite or convenient for working the tramways. The several provisions relating to the working of the tramways and the taking of tolls contained in any Act relating to any such tramway shall extend and apply to the Council, instead of to the former company. Clause 3 provides that the Council, on the one hand, and any company owning any tramway connected with any tramway of the Council, on the other hand, may enter into any agreement with respect to the exercise of running powers either by such company over the tramways of the Council, or *vice versâ*, provided always that during the currency of any such agreement all by-laws and regulations shall be observed by the Council or the company, as

Digitized by Google

the case may be, exercising such running powers. Clause 4 enacts that all the expenses of the Council incurred in the execution of the powers contained in this Act shall be defrayed as payments for general county purposes within the meaning of the Local Government Act, 1888.

Electric Lighting in Austria-Hungary.—Among the public buildings at Graz which have been lighted electrically are the Law Courts on the Stadtsquai, where 700 incandescent lamps are employed. The installation has been carried out by Messrs. Kremenezky, Mayer, and Co., of Vienna. The same firm have done the work in connection with the electric lighting of the business houses belonging to Raimund Noë, Albin Fleischmann, J. K. Klammerth, and G. Bachner, and the Zum Schwan and Florian Hotels.—Offers were lately invited by the Municipality of Werschetz, Hungary, for a scheme for the electric lighting of the town. Projects were presented by Messrs. M. Zeller and Co., the Helios Company, and Messrs. Ganz and Co. The Municipality have decided that the scheme of the last named is the most satisfactory. They intend to keep the electric lighting in their own hands. A central electric light station has been opened at Weinberge, near Prague, the work having been carried out by Messrs. Bartelmus and Co., of Brünn, the plans being prepared by their engineer, Dr. Stefan Doubrava. There are connected 3,000 16-c.p. incandescent lamps and eight 8-ampere arc lamps. An extension of the works is to be made.—The Ungarische Elektricitäts-Aktiengesellschaft, which own a large central station in Budapest, have established a small station for the lighting of Erlau and Fünfkirchen, the work being carried out by Messrs. Ganz and Co.

Crystal Palace School of Engineering.—The annual distribution of prizes and certificates to the students took place on Friday in the lecture-hall of the School of Art, Science, and Literature, Mr. J. H. Greathead distributing the certificates. Mr. R. G. Hodson presented the report of the examiners (Mr. Sidney R. Lowcock, Mr. R. Elliott-Cooper, and Mr. James N. Shoolbred), who praised the work done by the students. Forty-three attended the lectures: 37 were available for examination; 28 passed. The Chairman fully endorsed the examiners' opinion, and congratulated the students on their choice of a profession. Mr. G. T. Rait, chairman of the Crystal Palace Company, thanked the examiners. Mr. Lowcock, acknowledging the compliment, congratulated the school not only on its growth since his student days, 16 years ago, but on its improved accommodation. Mr. Shoolbred also responded. Dwelling on the rapid development of electrical undertakings, he estimated that, excluding telegraphs, about £20,000,000 were profitably invested in electric works in this country; £30,000,000 in France; £40,000,000 in Germany; £35,000,000 in Austria, Italy, Spain, and Switzerland; probably £10,000,000 in Russia, Sweden, Norway, and Denmark; perhaps £90,000,000 in the United States; £10,000,000 in Canada and other parts of America. Then there were electrical works in India, Australasia, and China. Altogether about £250,000,000 was invested in these enterprises throughout the world; the total for Europe being something like £115,000,000, for America about £100,000,000. It was nearly all the work of the last 10 years, a record surpassing every other, including those of railways, gas, and water.

Determination of Dielectric Constants.—Mr. W. Nernst discusses this question in a German contemporary. In the arms A B, A C of a Wheatstone bridge, two adjustable electrolytic resistances are placed; the two arms B C, C D contain two similar condensers consisting of two metal plates separated by a movable glass plate. The ends A D are connected with an induction coil and B C to a telephone in which silence or at least a minimum of sound occurs when $R_{ab} : R_{ac} = C_{db} : C_{dc}$. A condenser consisting of a nickel or platinum trough with a fixed metal plate in the interior can be placed in either arm D B or D C, and its capacity added to either of the measuring condensers, and this contains the liquid whose dielectric constant is to be measured. Minimum sound is then obtained by moving the glass of the measuring condenser. The arms D B, D C contain also auxiliary resistances, so that if the compound examined is not a perfect insulator its resistance can be also determined, since a minimum also results when $R_{ab} : R_{ac} = R_{db} : R_{dc}$. The condensers and other parts of the apparatus are calibrated once for all, and full details of the precautions and a discussion of the probable errors are given in the paper. The availability of the method is well seen by comparing the numbers which the authors obtained with it, and the determinations made by Landolt and Jahn. In the case of 13 hydrocarbons the mean difference is about 2 per cent., the results by this method being in almost all cases the higher. A number of measurements of the capacity of benzene, aniline, amylic alcohol, ethylic alcohol, and water at varying temperatures are also recorded; from the results the temperature coefficients are calculated, the dielectric capacity in each case decreasing with increasing temperature.

Electric Lighting in Germany.—Mr. M. Weiss, an hotel proprietor at Glewitz, has an electric light plant for lighting his establishment, and has supplied current to neighbouring premises. He has now joined Mr. F. Kochmann, a local brewer, in a scheme for supplying the electric light to the town generally.—A central electric light station has been opened at Oberehnheim. Power is obtained partly from the Ehnbach stream and partly from the overflow of the local waterworks. The work has been carried out by Messrs. O. L. Kummer and Co., of Dresden.—The Municipality of Bregenz propose to establish a central electricity station, using the water power of the neighbouring river. It is intended to supply current for lighting and power purposes, and for working the pumps at the waterworks.—Mr. Rix has brought forward a project for the electric lighting of the streets of Plön.—The electric light is being largely adopted at Strassburg.—At Nuremberg applications have been received for 26,000 incandescent lamps, and for motors of 450 h.p. The full capacity of the station will be for 56,000 incandescent lamps, 400 arc lamps, and motors of 1,400 h.p. It is expected that the agreement with Messrs. Schuckert and Co. will be signed next month.—It is intended to introduce the electric light into Kandorn.—Messrs. Schuckert and Co., of Nuremberg, are in negotiation with the local authorities of Brünn for the establishment of a central electricity station for the supply of current for lighting and power purposes, and possibly for an electric tramway.—A central station is to be established at Tuttlingen at a cost of £14,500. The work will be carried out by the Maschinenfabrik Esslingen, who will run the installation under the condition that the local authorities can buy it up after a certain lapse of time.—At Laibach the Municipality have decided to establish a central station.

Frankfort Central Station.—The central station at Frankfort-on-the-Maine, where trial runs have recently been made, is on the point of being officially opened. Originally the battle of the systems was fierce, but eventually the alternating-current method triumphed, and the contract for the machinery was given to Messrs. Brown,

Digitized by Google

Boveri, and Co., of Baden, Switzerland. The works were commenced last April, and in November the first generators were started. The site of the station is near the harbour and the railway bridge. There are three tandem steam-engines, each capable of giving 750 effective horse-power at a speed of 85 revolutions a minute. The pistons of the two cylinders drive a 24-ton flywheel, which at the same time serves as the field magnets. The engines are fitted with centrifugal governors and with automatic lubricating arrangements, and they can be worked with or without condensation. The boilers, of which there are eight, are equipped with the Kubon smoke-consuming appliance, and the working pressure is 135lb. The flywheel of the engine serves as the frame of the 64 field coils, which are fixed radially to the periphery. Around the flywheel is arranged a fixed armature, which also has 64 coils. The exciting dynamos are six-pole series machines, having drum armatures. The alternators give current at 3,000 volts, which is led to a main switchboard and thence to a distributing board, by means of which the current is passed along the feeders to the sub-stations. The feeders are laid to six points from which the high pressure current is distributed throughout the whole of the town to 92 transformer-chambers built in the ground. The transformers are arranged in oil, and reduce the high pressure to 120 volts. The feeders, as are also the distributing mains, are concentric cables of the Felten and Guilleaume type. The capacity of the station is 35,000 lamps, of which 10,000 are already connected to the mains, together with 29 motors of a total of 150 h.p.

Electric Lighting in France. — The Société Générale d'Electricité, which obtained the concession for the electric lighting of Chambéry, is offering to establish a central station at Aix-les-Bains.—The Bordeaux Municipality have voted the requisite funds for the establishment of an electric light station to supply light to the public gardens. It will probably ultimately be extended.—The Compagnie des Mines, of Bruay, Pas de Calais, have adopted the electric light. Two Armington and Sims steam-engines, each of 100 h.p., are employed to drive two dynamos. The electrical work has been done by the Société Alsacienne de Constructions Mécanique.—A central electric light station has been opened at Saint-Léonard, Haute Vienne, the work having been carried out by the Compagnie Française Thomson-Houston. Water power is utilised. The turbine is of 45 h.p., and made by Messrs. Grèzes and Piques, of Toulouse. This drives, by means of belting, a Thomson-Houston alternator giving current at 2,000 volts. The station is about a mile and a quarter from the town, and current is transmitted by naked overhead copper conductors to a transformer station. There are 60 200-c.p. lamps employed for street-lighting.—A competition is to take place at Saint-Dié among those desirous of obtaining the monopoly for the public and private electric lighting of the town. Offers are to be submitted to the Mayor by February 1, and will afterwards be examined by the Municipal Council.—The electric light has been introduced into Aouste, Drôme. Water power is utilised.—At Troyes, the municipal theatre is to be lighted by electricity. The Compagnie de l'Est intends to adopt the electric light at its Troyes-Ville and Troyes-Preyse railway stations, taking current from the Troyes central electricity works of the Compagnie Nationale de l'Electricité.—Some new arc lamps are to be erected at the harbour, Brest.—It is proposed to establish a central station at Châtillon-sur-Chalaronne, utilising the water power of the River Chalaronne.—Mr. Stulzmann, a Swiss engineer who has lighted Ferney electrically, is applying to the Municipality of Gex, Ain, for power to introduce the electric light there.—The electric light is to be introduced into the mining town of Langeac, Haute-Loire.—The Municipality of Moirans, Isère, offer a subvention for the best scheme for the electric lighting of the town.—Projects are on foot for the establishment of electricity works at Montereau, Seine-et-Marne.—M. Bastide has commenced work in connection with the central electric light station at Riez, Basses-Alpes, for which he has obtained a concession.

Utilisation of Niagara Falls.—A letter from Prof. G. Forbes, who has now returned from the United States, was published in the *Times* on Saturday last. The letter is as follows: "Nearly three years ago you published a letter from this place in which I gave some account of how the dreams of the engineer were in the act of being realised, and without injury to the natural beauties of the spot. Three years have passed, my work is ended, and it seems natural to continue the narrative and tell what these three years have brought forth. I am perched on the top of a small Eiffel tower, lately erected, and, casting my eyes up the river, over the house-tops and beyond the town, I see a new world created. There is a wide canal leading water into that gigantic power-house where three turbines are set up to drive three dynamos of 5,000 h.p. each. There is the bridge to carry cables across to the transformer-house. Inside the power-house the water is carried down pipes 7½ft. diameter into the turbines, and thence it passes through a 7,000ft. tunnel under the town, emerging below the Falls, and capable of developing 100,000 h.p. Far as the eye can reach extend the company's lands, with here and there a huge factory either now using the water power, or waiting for the electric supply. One of them uses 3,300 h.p., another 300, a third one 1,500, and that unfinished mill requires 1,000. You can see, far away, the model village for working-men, and improved sewage works with drainage, pumps for water supply, electric light, and well-paved streets. There, again, is the dock where ships from all parts of the great lakes can unload, and there a huge expanse of reclaimed land; while the whole is swept by the company's railway, seven miles long, connecting every factory with the great trunk lines. The power is transmitted by electricity, and the first work is to produce aluminium with 1,500 h.p. New types of machines have been devised for this work as also for every other purpose. All criticism as to cost of electric works has been swept away by the results achieved, and the efficiency of each type of machine is greater than has been attained before. All the machinery for the first working has been made and tested in the shops, and the last parts are now being set up. The plans for carrying the power to Buffalo, 18 miles distant, are complete. In a month or two factories will be in full operation; in a year Buffalo will be supplied; in two years the same company will be working the Canadian side of the Falls, and in 10 years (shall we say?) the whole of the 100,000 h.p. which can be supplied by the existing hydraulic works will be giving power to smokeless manufacturing towns. The period of planning the transmission scheme, of designing the greatest dynamos in the world, and of construction of the first plant, now closes. The financial period commences with the new year. The earning of dividends and the ordering of duplicate machinery is the future work of the company. In conclusion, it is difficult for me to say who were the boldest—the capitalists who embarked on the scheme before any plans were matured, or the manufacturers who moved their factories to this field before a single result had been achieved. The action of both was typically American, but their confidence was not misplaced. Their success is now assured."

Gravitation Water Supplies and Electrical Energy.—The rapidly extending use of water power for the generation of electricity at many places abroad, the *Engineer* remarks, has naturally directed attention to the home possibilities in this direction. These are soon found to be disappointing, the best water-power locations having been long ago utilised for various motive purposes. There are, it is true, numberless points on the smaller streams throughout the country capable of furnishing power for small lighting installations; but generally the water power in Great Britain not subject to old-established rights is meagre or capricious. In some parts of Ireland, however, there is abundance of water power capable of utilisation. But apart from natural sources, there is another and constantly increasing form of water power in the great works, completed and in progress, for supplying the inhabitants of cities, towns, and villages with potable water. Here, also, however, a very slight amount of investigation shows that though the power represented in many cases by the flow of water and its fall may be great, the energy capable of utilisation is generally small, and often practically non-existent. For instance, at Glasgow nearly 50,000,000 gallons of water flow daily into the city and suburbs from Loch Katrine, which has an elevation of about 350ft. above the lower streets of the town. The power represented by these figures would, if capable of employment for lighting by electricity, effect a great saving in the Corporation coal bill. But, of course, the water does not run direct from the highest to the lowest point. It runs first into the distributing reservoirs at Craigmaddie, situated some 50ft. below the level of Loch Katrine, and is conveyed mainly in open culverts, so that little power is derivable at its debouchment. From Craigmaddie the water is piped; but some of the natural elevations in Glasgow are over 250ft. in height, with buildings of about 50ft. elevation on their summits, so that in some cases the head of water does not suffice for the supply, and pumping is resorted to. In short, though in some of the lower districts there may be at times an excess of pressure, practically all the energy due to the head and volume of water is absorbed in its own distribution. Very similar conditions obtain in cities like Manchester and Liverpool. There are, however—especially in Scotland—many towns where the gravitation water supplies are capable of furnishing considerable quantities of electrical energy at a comparative small outlay and without detriment to the water distribution. To cite, a case a small town on the Clyde, with reservoirs at over 500ft. above the river level, gives its inhabitants a liberal supply of 600,000 gallons per day. To keep the pressure at the lower parts of the town within reasonable limits, the main pipe is broken 250ft. below the level of the reservoirs, the water discharging into a distributing-tank with an amount of energy equal to nearly 100 h.p. in the meantime unutilised. To have undertaken the construction of the works merely to get this power would have been out of the question; but the instance shows, the *Engineer* concludes, that it may be quite worth the attention of engineers, when laying out new works in hilly districts, to consider the power possibilities of their schemes, as there are no doubt many localities adapted for the combination of a power station and water-supply works.

The Marvellous (!) Primary Battery Again.—Judging from the reports now circulating in Scotch papers, the experience and results gained by many persons in the production of different kinds of primary batteries do not deter others from attempting the impossible—the discovery of a battery to replace the dynamo. In the present case it appears that two young Dumbartonians have devised a marvellous battery! As it would be a pity to destroy the humour of the statement in a Glasgow paper, we quote the following: "What these young Clydebank engineers are said to have accomplished is the discovery of a primary battery in which, while the decomposition of the zinc plates is rendered enormously slower, and the chemicals used of trivial value, the strength of the battery thus formed is very greatly increased. The matter has been taken up by a number of gentlemen in Glasgow, who have formed themselves into a syndicate, which has started with a capital of something like £4,000 to enable the young men to prove and develop their discovery. An arc lamp at Queen-street Station, Glasgow, has been as brilliantly lighted by one or two of the cells of the battery as by the power supplied from the big dynamos. The new form of battery is understood to include the use of common salt water, ash, bluestone, and other very cheap chemicals." Mr. E. T. Ruthven Murray, electrical engineer to the Aberdeen Corporation, in the course of an interview on the subject, at once threw cold water on the battery. He is reported to have said: "I do not think the matter has been properly gone into by scientific men who know what it is possible to do with primary batteries. If the statement which appeared in the newspapers is correct, there must be something very extraordinary in the invention, because, up to the present time, I do not think that with any two metals or substances known, a greater potential difference than that of about two volts can be maintained. I also notice in the report it is stated that an arc lamp has been brilliantly lighted by one or two of these cells. An arc lamp requires at least 45 volts to overcome the resistance of the arc and the lamp. Consequently with any ordinary cells—take storage batteries such as we have here—you would need to have 45 divided by 2—that is to say, 23 cells to maintain one arc; and though you could make a battery which would hold a sufficient current strength or number of amperes to light 25 arcs off the same cells—and that is the capacity of the batteries at the central station here—you would still require the 23 cells to enable you to maintain the requisite pressure to get the current through the lamps. It appears to me that the account of the supposed discovery has not been written by a technical man." Mr. A. W. Stewart, M.I.E.E., of Dalmuir, also dashes to the ground the fond hopes raised for this battery. He says: "A few nights ago I had the honour of inspecting the wonderful battery, which, from report, had burst all the incandescent electric lamps yet tested, none of them being able to withstand the enormous tides of current generated therein. The battery consisted of two sets of unassuming boxes, each about 2ft. square and 1ft. deep, inside of which were packed 15 glass jars containing the wonderful elements to be used hereafter in driving our ocean greyhounds at from 40 to 60 miles per hour. The inventor took up the positive and negative wires in his bare hands and placed them on the terminals of a small motor, which responded at once by setting off a-spinning as fast as its little wire-bound sides would allow it, considering that all the work it had to do was to overcome the friction of its own oily bearings. This was certainly very awe-inspiring to anyone accustomed with the running of motors, but on placing my finger on its pulley I found that the friction was too much, and it stopped altogether. Not having any instruments with me to measure the output of this 30-cell battery, I therefore tried a test, well known among electricians for very weak currents, and this was to place the positive and negative wire on each side of my tongue. I survived the feeble shock, and live to tell the tale."

PHYSICAL UNITS.

BY MAGNUS MACLEAN, M.A., F.R.S.E.

(All Rights Reserved.)

(Continued from page 655.)

MEASUREMENT OF ELECTRIC UNITS BY THEIR ELECTROMAGNETIC EFFECTS.

§ 76. *Quantity.*—Quantity can be measured practically by a ballistic galvanometer (1) when we know the steady current (§ 77) that gives unit deflection on it, or (2) when we know the dimensions of the ballistic galvanometer and the horizontal component of the earth's magnetism at the centre of its coil (§ 77). Quantity can also be measured by electro-chemical effects (§ 79).

§ 77. *Current.*—In the electromagnetic system currents can be measured (1) by their action on a magnetic needle, as described in last paragraph of § 55. This involves a knowledge of the horizontal component of the earth's magnetic force. An exact determination of this can be made by the Gaussian method of finding the deflection produced on a magnetometer needle by a magnet at a given distance, and then finding the period of the magnet vibrating under the earth's horizontal magnetic force, when suspended in the position occupied by the magnetometer in the deflection experiment.*

§ 78. Currents can be measured (2) by their mutual action on one another. Ampère has investigated the laws of mechanical action between conductors carrying currents; and he has shown that the action of a small closed circuit at a distance is the same as that of a small magnet placed at the centre of the closed circuit, provided that the axis of the magnet is at right angles to the plane of the closed circuit and that its magnetic moment is equal to the product of the area of the closed circuit into the current.

Hence we might define unit current electrodynamically as follows: Let there be two straight parallel conductors, unit distance apart, and carrying equal currents. Let one of them be of finite length, and the other very long. Then unit current flows in each of them when there is unit force between them per unit length of the finite conductor. This unit of electrodynamic current is $1/\sqrt{2}$ of the unit of electromagnetic current, or 7·07 amperes. It is not used in practice. Hence, to make this unit of current coincide with the electromagnetic unit of current, we must define it as that current which, flowing in each of our two conductors, produces two units of force per unit length of the finite conductor, when they are unit distance apart.

Electro-dynamometers and electro-dynamic balances measure currents by the mutual action of their coils on one another. The Board of Trade has accepted instruments of this type for measuring standard currents, in practice the recommendation of the Board of Trade Committee on electrical standards being "that instruments constructed on the principle of the balance, in which, by the proper disposition of the conductors, forces of attraction and repulsion are produced, which depend upon the amount of current passing, and are balanced by known weights, should be adopted as the Board of Trade standards for the measurement of current whether unvarying or alternating."

§ 79. Electric currents can be measured (3) by their electro-chemical action. Faraday has shown that when a current passes through an electrolyte the quantity of each substance decomposed is proportional to the quantity of electricity which passes. The ampere is thus defined as the unvarying current which, when passed through a solution of nitrate of silver in water (definitely specified in the report previously referred to), deposits silver at the rate of 0·001118 of a gramme per second. The balances referred to in (2) are standardised by the electrolysis of a solution of silver nitrate or of copper sulphate.

§ 80. *Resistance.*—Various methods have been used for the determination of resistances in absolute measure, and the reader is referred to the following papers and books for detailed descriptions and discussions of them: "On the Methods Employed for Determining the Ohm," by G. Wiedemann, *Phil. Mag.*, October, 1882, p. 258; "Comparison of Methods for the Determination of Resistances in Absolute Measure," by Lord Rayleigh, *Phil Mag.*, November, 1882, p. 329; "Electricity and Magnetism," by Clerk Maxwell, Vol. II., Chapter XVIII.; "Absolute Measurements in Electricity and Magnetism," by Prof. A. Gray, Vol. II., Part II., Chapter X., pp. 538 to 602.

§ 81. The tables of results in § 83 are taken from a report by R. T. Glazebrook to the British Association in 1891 on the "Absolute Resistance of Mercury." The methods referred to in the fourth column are fully described in the papers and books referred to in the previous section. Here it may be briefly stated that the method of the rotating coil, though first suggested by Weber, was first practically carried out by Clerk Maxwell, Balfour Stewart, and Fleeming Jenkin, in 1863, by an apparatus designed by Prof. Wm. Thomson (now Lord Kelvin). The method is sometimes known as the B. A. Committee method: "The coil of wire is made to revolve about a vertical diameter with constant velocity. The motion of the coil among the lines of force due to the earth's magnetism produces induced currents in the coil which are alternately in opposite directions with respect to the coil itself, the direction changing as the plane of the coil passes through the east and west direction. If we consider the direction of the current with respect to a fixed line in the east and west direction, we shall find that the changes in the current are accompanied with changes in the face of the coil presented to the east, so that the absolute direction of the current, as seen from the east, remains always the same. If a magnet be suspended in the centre of the coil, it will be deflected from the north and south line by the action of these currents, and will be turned in the same direction as the coil revolves. The force producing this deflection is continually varying in magnitude and direction; but as the periodic time is small the oscillations of the magnet may be rendered insensible by increasing the mass of the apparatus along with which it is suspended. The resistance of the coil may be found when we know the dimensions of the coil, the velocity of rotation, and the deflection of the magnet. The intensity of terrestrial magnetism enters into the measurement of the E.M.F., and also into the measurement of the current; but the measure of the resistance, which is the ratio of these two quantities, is quite independent of the value of the magnetic intensity."*

§ 82. Lorenz's method is as follows: "A circular disc of metal, maintained in rotation about an axis passing through its centre at a uniform and known rate, is placed in the magnetic field due to a battery current which circulates through a co-axial coil of many turns. The revolving disc is touched near its centre and circumference by two wires. If the circuit were simply closed through a galvanometer, the instrument would indicate the current due to the E.M.F. of induction acting against the resistance of the circuit. The E.M.F. corresponding to each revolution is the same as would be generated in a single turn of wire coincident with the circumference of the disc by the formation or cessation of the battery current. If this be called γ, and M be the coefficient of induction between the coil and the circumference, m the number of revolutions per second, the E.M.F. is $m\,M\,\gamma$. For the present purpose, however, the circuit is not simply closed, but its terminals are connected with the extremities of a resistance, R, through which the battery current flows, and the variable quantities are so adjusted that the E.M.F. $R\,\gamma$ exactly balances that of induction. When the galvanometer indicates no current the following relation, independent, it will be observed, of the magnitude of the battery current, must be satisfied,

$$R = m\,M;$$

and from this, M being known from the data of construction, the absolute resistance, R, of the conductor is determined."†

§ 83. TABLES OF RESULTS.

—	Observer.	Date.	Method.	Value of the ohm in centimetres; cross-section 1 sq. mm.; temperature 0° C.	
1	Lord Rayleigh	1882	Rotating coil	106·31	
2	Lord Rayleigh	1883	Lorenz method	106·27	
3	Mascart	1884	Induced current	106·33	
4	Rowland	1887	Mean of several methods	106·32	
5	Kohlrausch	1887	Damping of magnets	106·32	mean 106·31
6	Glazebrook	1882, 1888	Induced currents	106·29	
7	Wuilleumeier	1890	—	106·31	
8	Duncan & Wilkes	1890	Lorenz	106·34	
9	Jones	1891	Lorenz	106·31	
10	Strecker	1885	—	106·32	
11	Hutchinson	1888	—	106 30	mean 106·31
12	Salvioni	1890	—	106·33	
12*	Salvioni	—	—	106·30	
13	H. F. Weber	1884	Induced current	105·37	
14	H. F. Weber	—	Rotating coil	106·16	
15	Poiti	1884	Mean effect of induced current	105·89	mean 105·94
16	Himstedt	1885	—	105·98	
17	Dorn	1889	Damping of a magnet	106·24	
18	Wild	1883	Damping of a magnet	106·03	
19	Lorenz	1885	Lorenz method	105·93	

§ 84. From the average of these experiments the ohm is defined as the resistance offered to an unvarying electric current by a column of mercury at the temperature of melting ice, 14·4521 grammes in mass, of a constant cross-sectional area, and of length 106·3cm.

Calling this the Board of Trade ohm, or the international ohm, the following table gives the value of the principal practical units of resistance which previously existed:

Unit.	International ohm.	B.A. ohm.	Legal ohm 1884.	Siemens's ohm.
International ohm.	1	1·0136	1·0028	1·0630
B.A. ohm	0·9866	1	0·9894	1·0488
Legal ohm.....	0·9972	1·0107	1	1·0600
Siemens's ohm	0·9407	0·9535	0·9434	1

Thus to reduce British Association ohms to international ohms we divide by 1·0136, or multiply by 0·9866; and to reduce legal ohms to international ohms we divide by 1·0028, or multiply by 0·9972, etc.

§ 85. *Electromotive Force.*—Electromotive forces can be measured indirectly when resistances and currents are measured by any of the methods mentioned; for, by Ohm's law, the difference of potential between any two points of a circuit is equal to the product of the current passing into the resistance between the points. Electromotive forces can be measured directly as the ratio of the work done by the transfer of a given quantity of electricity to the quantity transferred. Lord Kelvin has determined, from data supplied by Dr. Joule, the E.M.F. of a single cell of Daniell's battery by this method.

(See "Applications of the Principle of Mechanical Effect to the Measurement of Electromotive Forces, and of Galvanic Resistances," by Lord Kelvin, *Phil. Mag.*, December, 1851. Reprinted in "Mathematical and Physical Papers," vol. i., p. 490.)

As a practical standard of E.M.F., the Board of Trade has taken the electrical pressure at a temperature of 15deg. C. between the poles or electrodes of the voltaic cell known as Clark's cell (specially prepared) as 1·434 volts. Corrections, similar to those mentioned regarding the ohm, must be applied to B.A. volts, legal volts, etc., to reduce them to Board of Trade volts or international volts.

§ 86. *Capacity.*—The capacity of a conductor is the ratio of the quantity of electricity in the charge to the E.M.F. producing it, and hence an indirect measurement of capacity is easily performed. It can be measured by a ballistic galvanometer when the resistance of the circuit in electromagnetic measure is known (§ 80).

MEASUREMENT OF ELECTRIC UNITS BY THEIR ELECTROSTATIC EFFECTS.

§ 87. *Quantity.*—The practical method of measuring a quantity of electricity is to measure the capacity of the conductor containing the charge (§ 90), and to multiply this by the E.M.F. producing the charge (§ 89).

§ 88. *Current.*—The practical method of measuring current is to find the difference of potential (§ 89), and the resistance (§ 91), and to divide the one by the other.

§ 89. *Electromotive Force.*—The practical method of measuring E.M.F. is to measure the force between two electrified bodies, for the difference of potential between them is proportional to the force exerted between them. Absolute electrometers are constructed on this principle.

§ 90. *Capacity.*—The capacity of a conductor is measured by comparing its capacity with that of a spherical conductor insulated at a distance from other conductors. The capacity of the latter is equal to its radius.

§ 91. *Resistance.*—Electrostatic resistance can be measured by allowing a body of known capacity (§ 90), and charged to a potential measured as in (§ 89), to discharge itself through the conductor whose electrostatic resistance we want to measure. This method is applicable only to conductors of large resistance.

§ 92. Now that we know how to measure the electric units electrostatically and electromagnetically, we can find the ratio of the one to the other—that is, we can experimentally find what was denoted by v in § 65. This velocity, v, has been determined experimentally by measuring in electrostatic units and in electromagnetic units:

	Ratio.
I. Quantity, §§ 87 and 76	v
II. Current, §§ 88 and 77, 78, 79	v
III. Resistance, §§ 91 and 80-83	$1/v^2$
IV. E.M.F., §§ 89 and 85	$1/v$
V. Capacity, §§ 98 and 86	v^2

PRACTICAL NOTES ON DYNAMO CALCULATION.*

BY ALFRED E. WIENER.

(Continued from page 717.)

36. *Total Flux to be Generated in Machine.*—The total flux to be generated in any dynamo is the product obtained in multiplying its useful flux by the factor of its magnetic leakage:

$$\Phi' = \lambda \times \Phi = \lambda \times \frac{6 \times b \times E \times 10^9}{K \times N} \quad . \quad . \quad (109)$$

Φ' = total flux to be generated in machine, in lines of force;
Φ = useful flux necessary to produce the required E.M.F. under the given conditions, from formula (91);
λ = factor of magnetic leakage (see Chapters 37 to 40).

The value of the total magnetic flux in a dynamo directly determines the sectional areas of the various portions of the magnetic circuit in the frame (see Part III.), and since the magnetomotive force required depends upon the total

* From the *Electrical World* (New York).

Digitized by Google

magnetic flux to be effected, has a direct influence also upon the magnetic winding. In calculating a dynamo-electric machine, therefore, it is of great importance to compute the actual value of the total flux, and, consequently, to predetermine with sufficient accuracy the amount of the magnetic leakage.

But since the dimensions of the magnetic circuit depend upon the total flux to be generated, the accurate value of the total flux, however, is given by the coefficient of magnetic leakage, which, in turn, for a newly-designed machine is to be calculated from the dimensions of the magnet frame, it is necessary to proceed as follows:

An approximate value of λ for the type and size of dynamo in question is taken from Table LII., Chapter 40, and the corresponding approximate total flux calculated from formula (109). With the value of Φ' thus obtained, the principal dimensions of the magnet frame are determined according to the rules given in Part III. The dimensions now being known, the probable leakage factor, λ, can be figured from formula (110) or (111) respectively, Chapter 37, the single terms of which are found by applying the formulæ and rules given in Chapters 38 and 39 to the particular type under consideration. From formula (109), finally, the accurate value of the total flux is obtained. Should the latter prove so much different from the assumed approximate value of Φ', as to necessitate a change in the dimensions of the frame, then the calculation of λ will have to be partly or wholly repeated.

That such a calculation of the probable leakage factor is necessary in every single case, is evident from the fact that not only the leakage in two machines of same general design, and even of approximately the same size, which are merely differently proportioned in their essential parts, may widely differ from each other, but that in one and the same dynamo the amount of the leakage can be considerably varied by using armatures of different core diameters in its magnetic field.

From the same reason it can also be concluded that the method of assuming a valve of λ from previous experience with a certain type, or even with an individual machine, is an entirely unreliable one, and that the calculation of the magnetomotive force based upon such an assumption cannot be depended upon.

The author's method of predetermination of the magnetic leakage from the dimensions of a machine to the process of calculation, to within but a few per cent. of the actual value, is given in the following Chapters 37, 38, and 39 (Prof. Forbes*).

Logarithmic formulæ (2), heretofore employed for the computation of the magnetic leakage, being too cumbersome for the practical electrical engineer, the writer believes that by his set of simple geometrical formulæ contained in Chapter 38 he has removed some of the difficulty in leakage calculations.

37. *Formula for Probable Leakage Factor.*—Since air is a conductor of magnetism, the conditions of the magnetic circuit of a dynamo-electric machine resemble those of a closed metallic electric circuit immersed in a fluid. In the latter case the main current will flow through the metallic conductors, but a portion will pass through the fluid. Similarly for the magnetic circuit, the main path for the magnetic flux being the magnetic circuit of the dynamo, consisting of the iron field frame, the air-gaps, and the armature body. The amount of electric current passing through the surrounding medium, the fluid, depends upon the ratio between the conductances of the main to the shunt paths. In order to calculate the amount of magnetic leakage in a dynamo, therefore, it is, analogically, only necessary to determine the ratio between the permeances of the useful and the stray paths.

The leakage factor in any dynamo having a smooth armature can accordingly be expressed as the quotient of the total joint permeance of the systems by the permeance of the useful path. But since the reluctance of the iron portion of the main path is very small compared with that of the air-gaps, the sum of their reciprocals—that is, the total permeance of the useful path is practically equal to the permeance of the gaps; hence, the permeance of the gaps can be taken as a substitute of the permeance of the whole magnetic circuit within the machine, and we obtain the following formula for the probable leakage factor of any dynamo having a smooth armature:

$$\lambda = \frac{\text{Joint permeance of useful and stray paths}}{\text{Permeance of useful path}};$$

or,
$$\lambda = \frac{P_1+P_2+P_3+P_4}{P_1} \quad . \quad . \quad . \quad (110)$$

where P_1 = relative permeance of the air-gaps (useful path);
P_2 = relative average permeance across magnetic cores .....
P_3 = relative permeance across pole-pieces...
P_4 = relative permeance between pole-pieces and yoke .....
(stray paths).

The relative permeances—by which are understood the absolute permeances divided by the magnetic potential, and which, therefore, include a constant factor on account of the units chosen—are taken for convenience; for in each individual case the maximum magnetic potential is the same for all permeances, and a constant numerical factor, if absolute permeances were used, would be common to all terms in (110), and consequently would cancel.

In order to obtain the probable leakage factor for toothed and perforated armatures, the "factor of armature leakage" (Chapter 8) is to be introduced, and we have for this case:

$$\lambda' = \lambda_1 \times \lambda = \lambda_1 \times \frac{P_1+P_2+P_3+P_4}{P_1} \quad . \quad (111)$$

Numerical values of λ for various kinds of armatures are given in Table XI., Chapter 8.

38. *General Formulæ for Relative Permeances.*—In order to obtain the values of the permeances of the various paths we start from the general law of conductance:

$$\text{Conductance} = \left\{\begin{matrix}\text{conductivity}\\ \text{of medium}\end{matrix}\right\} \times \frac{\text{Area of medium}}{\text{Distance in medium}},$$

so, in our case of magnetic conductance:

$$\text{Permeance} = \text{permeability} \times \frac{\text{Area}}{\text{Length}}.$$

Since the permeability of air = 1, the relative permeance between two surfaces can be expressed by the general formula:

$$P = \frac{\text{Mean area of surface exposed}}{\text{Mean length of path between them}} \quad (112)$$

From this, formulæ for the various cases occurring in practice can be derived.

(*a*) *Two Plane Surfaces, Inclined to Each Other.*—In order to express, algebraically, the relative permeance of the space between two inclined plane surfaces, Fig. 49, the mean path is assumed to consist of two circular arcs joined by a straight line tangent to both circles, said arcs to be described from the edges of the planes nearest to each other, as centres with radii equal to the distances of the respective centres of gravity from these edges.

Hence

$$P = \frac{\frac{1}{2}(A_1+A_2)}{\frac{c+a_1+a_2}{2} \times \frac{\pi}{2} \times \frac{\alpha}{180}} \quad . \quad . \quad . \quad (113)$$

where A_1, A_2 = areas of magnetic surfaces;
c = least distance between them;
a_1, a_2 = widths of surfaces A_1 and A_2 respectively;
α = angle between surfaces A_1 and A_2.

(*b*) *Two Parallel Plane Surfaces Facing Each Other.*—If the two surfaces A_1 and A_2 are parallel to one another, Fig. 50, the angle closed is $\alpha = 0$deg., and the formula for the relative permeance, as a special case of (113), becomes:

$$P = \frac{\frac{1}{2}(A_1+A_2)}{c} \quad . \quad . \quad . \quad . \quad (114)$$

(*c*) *Two Equal Rectangular Surfaces Lying in One Plane.*—In case the two surfaces lie in the same plane, Fig. 51, they enclose an angle of $\alpha = 180$, and the permeance of the air between them, by formula (113), is

$$P = \frac{a \times b}{c + a \times \frac{\pi}{2}} \quad . \quad . \quad . \quad . \quad (115)$$

* Geo. Forbes, *Journal* Soc. Telegraph Engineers, XV., p. 531, 1886.

Digitized by Google

a = width of rectangular surface;
b = length „ „ „ ;
c = least distance between surfaces.

(*d*) *Two Equal Rectangles at Right Angles to Each Other.*—If the two surfaces are rectangular to each other, Fig. 52, the angle $\alpha = 90$deg., formula (113), consequently, reduces to

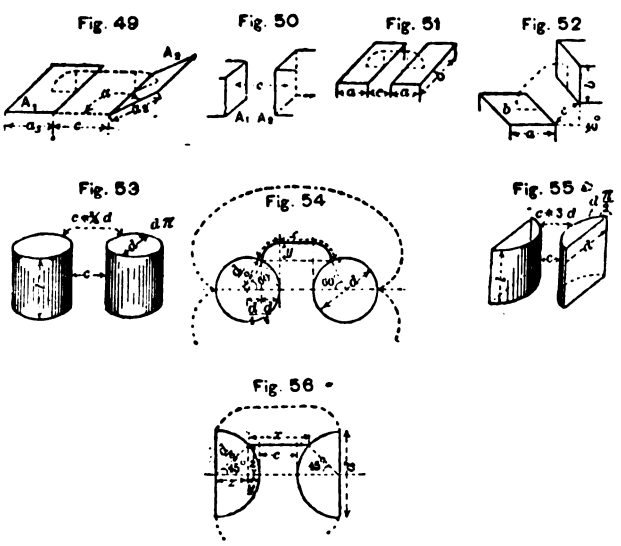
$$P = \frac{a \times b}{c + a \times \frac{\pi}{4}} \quad . \quad . \quad . \quad . \quad . \quad (116)$$

(*e*) *Two Parallel Cylinders.*—In case the two surfaces are cylinders of diameter d and length l, Fig. 53, the areas of their surfaces are $d\pi \times l$; and if they are placed parallel to each other at a distance c apart, the main length of the magnetic path is $c + \frac{3}{4} d$; hence the permeance of the air between them:

$$P = \frac{d \times \pi \times l}{c + \frac{3}{4} d} \quad . \quad . \quad . \quad . \quad . \quad (117)$$

In this formula the expressions for the mean length of the path is deduced from Fig. 54, in which it is assumed that the mean path consists of two quadrants joined by a straight line of length c, and extends between two points of the cylinder peripheries situated at angles of 60deg. from the centre line.

Since in an equilateral triangle the perpendicular,



dropped from any one corner upon the opposite side, halves that side, the perpendicular, from either of the end points of the mean path upon the centre line, bisects the radius of the corresponding cylinder circle, and the radius of the leakage-path quadrant is $y = \frac{a}{4}$, hence the length of the mean path:

$$\chi = c + y \times \pi = c + d \times \frac{\pi}{4},$$

or, approximately:

$$\chi = c + \tfrac{3}{4} d.$$

This approximation even better meets the practical truth, as most of the leakage takes place directly across the cylinders, and the mean path, therefore, in reality is situated at an angle of somewhat less than 60deg., which was taken for convenience in the geometrical consideration.

(*f*) *Two Parallel Cylinder Halves.*—If two cylinder halves face each other with their curved surfaces, Fig. 55, the mean length of the magnetic path is $C + \cdot 3\, d$, where c is the least distance apart of the curved surfaces, and d the diameter of the cylinders, and we have for the permeance:

$$P = \frac{d \times \frac{\pi}{2} \times l}{c + \cdot 3\, d} = \frac{d \times \pi \times l}{2\, c + \cdot 6\, d} \quad . \quad . \quad . \quad (118)$$

The mean length of the path is geometrically found from Fig. 56, as follows:

$$2 z^2 = \left(\frac{d}{2}\right)^2; \quad z = \frac{d}{2}\sqrt{\frac{1}{2}};$$

$$\therefore y = \frac{d}{2} - z = \frac{d}{2}\left(1 - \sqrt{\frac{1}{2}}\right) = \cdot 15\, d;$$

$$\chi = c + 2\, y = c + \cdot 3\, d.$$

For in this case the extent of the leakage field is much smaller than in that of full cylinders, and the mean path can be assumed a straight line meeting the two semi-circles at an angle of 45deg. from the centre line.

(To be continued.)

ON THE EFFECT OF MAGNETISATION UPON THE DIMENSIONS OF IRON RINGS IN DIRECTIONS PERPENDICULAR TO THE MAGNETISATION, AND UPON THE VOLUME OF THE RINGS.*

BY SHELFORD BIDWELL, M.A., LL.B., F.R.S.

A recent communication† to the society contained an account of some experiments relating to the effects of magnetisation upon the dimensions of two iron rings, one of which was annealed and the other hardened. The rings had the form of short cylinders about 6cm. in diameter, 3cm. in height, and 0·4 cm. in thickness. The experiments in question were concerned with the circumferential variations which took place along the lines of magnetisation. Those to be here described deal with the concomitant variations in the height of the cylinders (width of the rings) transversely to the magnetisation. On the assumption that variations similar to the latter occur at the same time in the thickness of the metal, it is possible to deduce the changes in the volume of the ring which attend magnetisation.

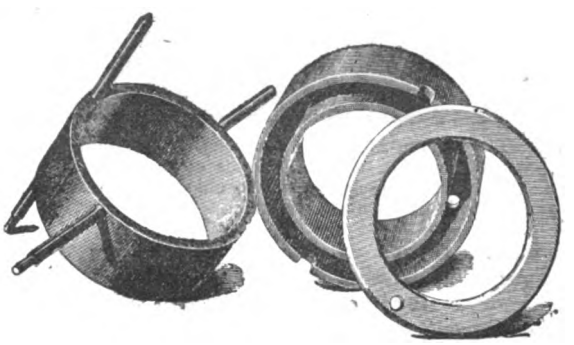


FIG. 1.

Fig. 1, from a photograph, shows how the rings were prepared for the experiments. Four brass rods were hard-soldered to the iron, two of them being in a line with a diameter, while the other two were attached to the edges opposite to one another, and parallel to the axis of the ring. The ring was inserted in a wooden case, also shown, through holes in which the four brass rods projected. Insulated wire for carrying the magnetising current was wound over the wooden jacket.

For the new experiments the ring was placed in a horizontal position, one of the edge rods resting upon a brass socket on the adjustable base of the instrument, and the other, which had a chisel-shaped end, actuating the lever.‡ To counterbalance the weight of the ring a horizontal arm, carrying a sliding weight, was fixed to the lower rod.

It need hardly be said that the experimental difficulties in the way of determining to a ten-millionth part the changes which took place in a length of less than 1¼in. were very considerable.

The annealed ring will, as before, be distinguished as Ring I., and the hardened one as Ring II.

The changes observed in the widths of the two rings (transversely to the magnetisation) are indicated in Table I. and in the curves of Fig. 2. It will be seen that they are quite similar in the two cases, little or no effect being produced by annealing. Under gradually ascending forces both rings first become narrower, and then recover their

original width, and ultimately become wider than when unmagnetised.

TABLE I.

Ring I. (annealed)		Ring II. (hardened)	
Magnetising force, C.G.S. units.	Elongations in ten-millionths.	Magnetising force.	Elongations.

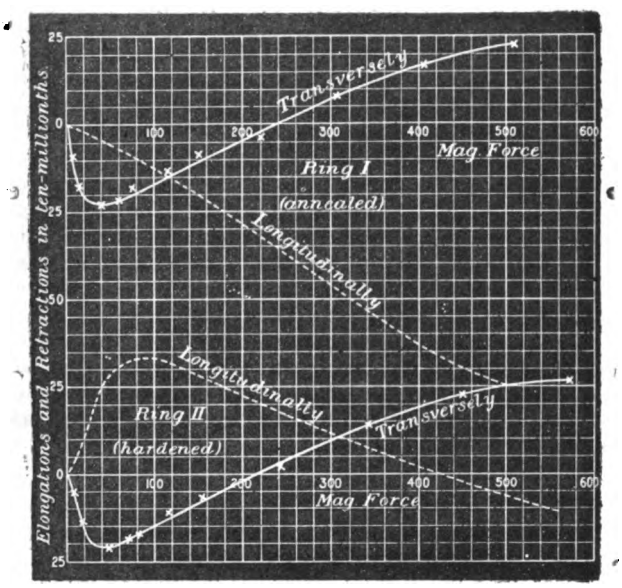

FIG. 2.—The curves marked "longitudinally" relate to circumferential changes, *along* the lines of magnetisation. Those marked "transversely" relate to changes in the width, *perpendicularly* to the magnetisation.

The only previous experiments that I know of relating to magnetic changes of dimensions in directions perpendicular to the magnetisation are those of Joule,* who used a piece of iron gas-piping one yard long, and ⅜in. in mean diameter, having an insulated wire inserted into it and bent over the sides, so as to form a magnetising coil of one and a half convolutions. The greatest current he used seems to have been about 12 amperes, and the magnetising force therefore about eight C.G.S. units. With this he found a contraction in the length of the pipe of seven ten-millionths, a result which agrees very well with that obtained by myself for the same small magnetising force.

As was shown in my last paper, the effects along the lines of magnetisation are very different in the two rings. The annealed ring (Ring I.) begins to contract circumferentially with the smallest forces, and continues to contract with the large ones; while the hardened ring expands with small forces and contracts with large ones. These effects are indicated in the figure by the dotted curves.

By combining the results of the old and of the new experiments we can ascertain the nature of the changes produced by magnetisation in the volumes of the rings.

If k = elongation (+ or −) along the lines of magnetisation;

l = elongation (+ or −) transversely to the lines of magnetisation;

then the increment or decrement of volume when the ring is magnetised is approximately† $k + 2l$

From the two sets of curves in Fig. 1 corresponding values of k and l can be found, and thence the changes of volume may be deduced. These are given in Table II. and Fig. 3, which show that the volume of the annealed ring is rather suddenly diminished by a small magnetising force, passes a minimum under a force of about 50 units, and then slowly increases, until, with a force of 500 units, it is about 30 ten-millionths less than at starting. The unannealed ring also at first suffers diminution, but its original volume is recovered with a force of about 90, and with higher values is increased.

TABLE II.

Magnetising force, in C.G.S. units.	Increments and decrements of volume in ten-millionths.	
	Ring I. (annealed).	Ring II. (hardened).
10	−27	−11
20	−42	−20
30	−47	−20
40	−51	−17
60	−51	− 9
80	−48	− 2
100	−46	3
140	−42	11
180	−39	17
220	−37	22
260	−35	26
300	−32·5	30
400	−30	40
500	−29	44

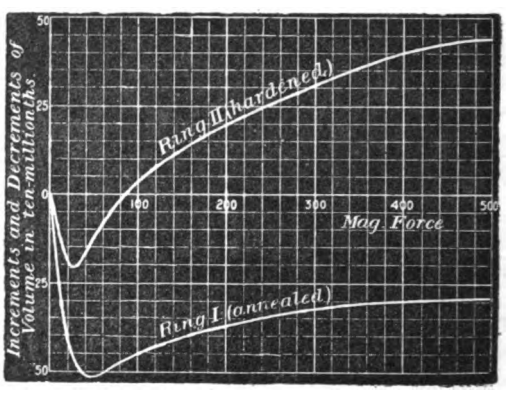

FIG. 3.

The behaviour of this latter ring may be regarded as probably similar to that of the great majority of rods and rings, the annealed ring used in these experiments being the only specimen of iron that has yet been found to contract along the lines of magnetisation with the smallest forces that produced any effect at all.

Experiments upon the volume changes produced by magnetisation have been previously made by Joule, Barrett, and Knott.

Joule* concluded that the volume of an iron bar was altogether unaffected by magnetisation, even though the magnetising current which he employed "was quite equal to saturate the iron." It was at that time believed that "saturation" was produced by a force of from 80 to 100 units, and, assuming that Joule's force was of about that value, an inspection of the curve for unannealed iron in Fig. 3 will show the probable reason of his having failed to detect any change of volume. There is, in fact, none at all with a force of about 90 units.

Barrett,† experimenting in the same manner as Joule, "enclosing the bars in a vessel of water terminating in a capillary tube, and surrounding the vessel by a powerful magnetising helix," also obtained a negative result, perhaps for the same reason.

Knott's‡ experiments were made with hollow iron tubes 45·7cm. in length, 3·84cm. in external diameter, and of different bores, ranging from 0·7cm. to 3·19cm. "Each tube was closed below, and into the upper end a nut screwed tightly, through a perforation in which issued a fine capillary glass tube. The nut was adjusted under water, so that the whole of the interior space of the metal tube was filled with liquid, and also part of the glass tube. When the tube was set vertically in the heart of the magnetising coil, the changes of volume were measured by the motions of the liquid meniscus in the capillary tube." "A few experiments were made on the external change of volume of a few of the tubes, which were enclosed in a thin-walled brass tube. The brass tube yielded because of its thinness, so that the results were not certain. But

there was no doubt that with the specimens of iron tried there were large changes of volume."

The changes observed by Knott in the interior volume appear in the case of a tube of large bore to have been of the same nature as those in my unannealed ring; while with a tube of smaller bore they rather resembled the changes exhibited by the annealed ring. His published investigations are, however, only of a preliminary character, and it is not at present possible to make a satisfactory comparison between his results and my own. But he was undoubtedly the first to show that magnetisation is generally attended by considerable changes of volume.

ELECTRIC LOCOMOTIVES FOR SERVICE IN TUNNELS.

Some time ago a contract was entered into with the General Electric Company to furnish motors to propel the trains of the Baltimore and Ohio Railway through the Howard-street tunnel. Conductors to furnish the power are now being placed in the roof of the tunnel. From the masonry lining is suspended an iron trough, supported by Z-bars, containing the conducting wires. The engine will be propelled by combination trolleys, four poles being used. The locomotive consists of a double set of trucks, each having two axles and four driving wheels. On each axle is mounted a 300-h.p. gearless motor supported on spiral springs resting on the frame of the truck. The motor fields are of the iron-clad type, each with separate windings embedded in a mica-lined slot, cut into the curved body of a laminated iron armature.

The axles of the locomotive pass through the hollow shaft on which the armatures are mounted, these shafts resting on the bearings of the motor frame and being connected to the axles by universal couplings, this arrangement of parts allowing freedom of motion in all directions. Each commutator is provided with four sets of brushes, the motors being manipulated by parallel controllers in the cab. The motor can be used for pushing or pulling, and will work in either direction, it being simply a double engine. Each locomotive will have a capacity of 1,200 h.p., and will weigh nearly 100 tons; it will also be equipped with air brakes, and a whistle worked by a small auxiliary motor within the cab. It is expected that these electric locomotives, of which there will be three in use, will develop a speed of 30 miles an hour, and will propel trains over the Belt Line Railroad between Camden Station and Huntington-avenue as quickly as could be done by steam.

If a freight train is to pass through the tunnel, the motor will be coupled on behind, and will push the train and its locomotive through to Bolton Station, whence the two machines will run the train up grade to Huntington-avenue, where the electric motor will be detached without stopping the train. With passenger trains, the electric locomotive will couple on ahead, pull the train through to Bolton Station, and there leave it, while passengers are getting on and off.

The power-house is in process of erection at the south end of the Belt line below Camden Station. The excavations and embankments of the Belt Line Railroad are all completed, a small part of the masonry on the retaining walls of the Bolton Lot cut remaining unfinished. Tracks are laid over the entire course, but not yet ballasted. The electrical engineers are at work in the tunnel, and workmen are crowding up the walls of the power-house as rapidly as possible. Finishing touches are being put upon the bridges and masonry, and the greater part of the work will be completed by January 1. Trains can be run over the line soon afterwards, while the depôts are building and final repairs to the cuts and embankments are being attended to.

THE OLD GAS-MAIN HAS A TALK WITH THE NEW ELECTRIC LIGHT MAIN.

SCENE.—MOUNT EPHRAIM PROMENADE, TUNBRIDGE WELLS.

Gas-Main.—Hello! What's this a shakin' and a worrin' of me just lately? Here have I bin a restin' for years and doing my duty quietly, and no notice a taken of me, and now—why, what a queer little main it is they are puttin' in a top of me. It ain't for water and it ain't for gas as I know of.

Electric Light Main.—No, certainly not. I am the new electric light main, and am going to put you out of use after a time, so they tell me. At present I am what they call "dead," so there is no great harm in me yet. That is an odd state to be in before one is alive, isn't it, old man? However, I don't want to be bad friends with you; we must try and get on as well as we can together, so I am glad to hear you laugh at my little joke.

G.—Larfin'—can't help it—but it warn't because you said you was dead; you'll be lively enough presently, and have to take care you don't make dead 'uns of some of them 'ere chaps as handle you about so easily. I was a smiling 'cause you said you was going to put me out of use. That won't do—but as to being friends I hopes we shaull be—I've been or hearin' a good deal about you lately, because sometimes I have to work round to the Council-chamber, and light them up—but my word, what hard names they do use when they are talkin' about you—you'd think they was all a swearin' at one another if you didn't know their karacters was above it. The only wonder is as the town as taken you up so strong, instead of letting one of these 'ere limited companies try their luck fust, 'specially just now as money is so flush; they say you can get as much as you like for nothing.

E.—Well, anyway, the town *is* going to try first, old comrade. They can get money *almost* for nothing, and they are quite certain it will pay; and if it don't exactly do that, they have no shareholders to look upon the dividends, and so they are making a start and bowling me along Mount Ephraim. It's a pretty place, and I shall light it up in fine style.

G.—Humph! very likely; but I shall go on about the same, I reckon. I remembers when they first put me down what a hubbub there used to be. I went for oil, taller candles, and rushlights, and such things as they called lights in them days; and I fancy we warn't long after we gave them notice a-putting them out. But then they warn't much to go agin, was they—not like gas? specially when the article putty good, and nothing to complain as to price, and they always gets as much as they want. They did abuse us at first, I can tell you. Thought we should blow them all into the next world afore some on them as warn't quite certain as to their state of mind wanted to go, but, howsomever, here I am, and, not as I know of, haven't done no harm to no one since I bin here. They have guv you a little turn that way, haven't they?

E.—Oh, yes! They have said some very hard and false things about me, and want to make out I am dangerous, and go out just when I am wanted, and other things like that—all prompted by jealousy and fear that my superior light will be so manifest to all that they will soon welcome me into their homes, as well as want me to light the streets. You see, as time goes on, I know how to manage better, and don't go skipping about like a skyrocket, as I used to. At times I get a little jerky even now, as very small things upset me, and they have an awful trouble to keep me right sometimes, but from what I hear they know what they are about down here. They say they are a very clever lot.

G.—Well, at fust they was some time a finding out that it must be a wery small hole as I can't get out of, so we are both about alike that way, but I suppose they never maligned you as much as to say you would come cheaper than me. Now, you was a saying that this here is a beautiful promenade, and so it is. There ain't a better in England—fine air, fine views, and all that sort of thing; but all I hopes is that they will give you a better chance than they guv me—I've never had the same chance here as I've heard they guvs 'em in some towns. I'd guv them plenty of light if they'd use me properly, and show them what could be done, but, howsomever, I'm glad you won't be under the old committee, as liked to keep the place in darkness for fear of spending a penny. Let's see, I ain't good at new names, what do they call themselves now?

E.—The Lighting Committee.

G.—The Lightening Committee—then I suppose it 'ill be all electricity?

E.—No, the Lighting Committee.

G.—Oh, I sees, some of one and some of t'other, just as it takes them; give me the best and take the worst themselves, I reckon, but, as I said afore, I hopes they will guv you a better chance than t'other one did me. Why, look at some places in the town, what a disgrace it is. They do say, as people as come here to the Brighton station at night, when they come out of the well-lit station into the road can't hardly see which way to turn. They might put a few hextra lamps down that road, but perhaps they have been waiting for you to come along. Anyhow, the more light one gets at night, the more cheerfuller it will be all round. Well, good-bye, young spark, glad to make your acquaintance, hope you will enjoy your Christmas, and that we shall lay alongside one another for many a day; but mind, none of your skylarks, and if you do get a singeing anybody when they make you alive, don't be mean enough to lay it off on me—that's all.—*Tunbridge Wells Advertiser.*

THE PROGRESS OF ELECTRICITY.

Even to-day one hears the mild objection sometimes raised by well-meaning but very ignorant individuals—ignorant on this point at least—against the use of electric light or power in any of the well-accepted forms, on the score that the entire science "is in its infancy"! Nothing could well prove the fallaciousness of this idea more than the tendency which has been manifested, especially during the past year, in the direction of effecting economies in methods and appliances for generating and distributing electric energy for all purposes. So far from electrical engineers being yet engaged in experimenting upon broad principles and fundamental devices, they have for some time past been occupied in making the detailed improvements that become necessary to satisfy human desire for perfection of work and economy, after the general foundation of a science has been thoroughly and soundly erected.

The electrical industry does not now concern itself so much with devising new dynamos, new motors, or new lamps that embody principles of a different nature to those at present in use, but endeavours rather to improve the mechanical and electrical details of these appliances, and to find out, if possible, more economical combinations of methods now available rather than absolutely novel modes of obtaining, distributing, and using electric energy. Of course, the efforts of abstract research are not relaxed; they can never be so, altogether—thanks to human ambition that continually aims at still greater perfection—and it would be a sad day for science in general, and electricity in particular, when further investigations in pure science were ceased. These are now, however, left more to the teachers and investigators—to men like Hertz and Tesla, whilst the commercial improvements of latter days tend more to concrete perfection of details.

In regard to the latter, it is, of course, impossible to deal with or even take note of the numerous developments that the past year has brought out; probably there is not a single firm engaged in the manufacture, erection, or use of electrical appliances that would be unable to show some new or improved device effecting small economies, and due to the ingenuity of themselves or their employés. Some brief mention may, however, be made of the principal improvements in adapting more economical methods to the generation of electric energy. Thus the present year has seen a very notable increase in the use of what would otherwise be wasted sources of power, for developing energy in central stations that supply light and power circuits. Take, for instance, the refuse destructor plants not only specified for erection here and there in different localities where conditions favour their use, but actually at work with a considerable amount of success and economy. Water power has also come to the front, and to the limited extent which the physical character of this country will allow, it must undoubtedly occupy a still more prominent place in the future.

Both these methods have been introduced or used for the sole purpose of effecting an economy in the

Digitized by Google

cost of electric energy, the electrical apparatus remaining in essence pretty much the same as before; and instances of their use will serve to show very clearly in what directions commercial improvements are now being attempted.

Still another is yet to be spoken of. We refer to the use of gas and gas motors in the electricity supply station, instead of steam boilers and engines. The economical ratio between light or amount of illumination from a given quantity of gas when burnt in gas jets and when passed through a gas-engine which operates a dynamo and arc lights, is too well known and threadbare to require mention in these pages; but the great economy obtained by converting raw fuel into gas for use directly in gas motors as compared with its combustion in steam-boilers which supply steam-engines as prime movers in an electricity station, has not hitherto been made so clear, largely because the available appliances were suited to special conditions, and did not possess characteristics which could be modified to satisfy any demands.

No little credit is due in this respect to the efforts of Mr. Thwaite and his co-workers for developing a practical method and apparatus which may serve under almost any conditions to give the economy thus claimed for gas instead of steam power. It is to all intents and purposes clearly proved that at any rate in the gas-generating plant there are no further difficulties to be faced, on whatever scale the supply of power be based. What now remains to be effected is for the makers of gas-engines to show that they are capable of turning out prime motors of a size and type as large and economical as has long been done by the firms whose speciality is the construction of steam-engines. There seems every promise of satisfaction in this respect. Hardly a week passes by without the engineering papers chronicling, perhaps in illustrated detail, the construction of large and powerful gas-engines, of a capacity equal to 100 h.p. and upwards to perhaps 600 h.p. These are, moreover, in some cases intended for service in electric energy development, and not only for lighting, but for power purposes also: one engine of 100 h.p. or more has been put down lately for operating an electric tramway, though, it is hardly necessary to say, not in this country, unfortunately.

There is no little promise for improved methods of this kind, and their use is much to be favoured on every hand, not merely with the idea of change or of doing away with what we now depend upon (each method will probably have its own most suitable field of service, and room will exist for all, according to local conditions), but to promote true economy, and show the elastic nature of electrical working as a full and complete answer to any statement respecting its presumed elementary state.

Telegraphy in Morocco.—The question of facilities being afforded for extending the British cable system from Tangiers to several places on the western coasts as far as Mogodor is being pressed upon the Moorish Government by Mr. Salow, the British Minister.

THE ELECTRIC-PHŒBUS ACCUMULATOR.

Our French contemporary the *Revue Industrielle* states that the Compagnie Générale d'Electricité in Paris is producing, under the title of the "Electric-Phœbus," an accumulator in which the grid very firmly holds the active material and prevents it from falling, a matter which is favourable to mechanical resistance and the duration of the battery. It is submitted that the composition and special treatment of the active material allow of one obtaining a degree of porosity sufficient to ensure the penetration of the electrolyte to the core of the plates, and also prevent expansion. Experiments made with this type of accumulator at the Laboratoire Central d'Electricité under a normal rate of discharge (one ampere per kilogramme in average types) have given a capacity of 14 ampere-hours per kilogramme of electrode mounted, this including the weight of the connecting bars and the insulation of the plates. This capacity is said to be obtained by arresting the discharge when the difference of potential at the terminals of the accumulator falls to 1·85 volts. It is possible in case of necessity to discharge the accumulators without inconvenience at double the normal rate, the only disadvantage being a reduction in their efficiency in watts.

The commercial accumulator cells measure 220mm. in length by 100mm. in width and 8mm. in thickness; they are mounted in lead supports, surrounded by pitch pine, and assembled without metallic pieces; porcelain separators are used to keep the plates apart, and all the connecting parts of the electrodes are of inoxidisable metal. The company also construct for laboratory work and domestic lighting a type of accumulator having ebonite or glass supports and indiarubber separators. These cells are 95mm. by 110mm. and 6mm. Portable accumulators are also made on this method.

WIRE LOSSES, OVER-COMPOUNDING OF DYNAMOS, AND REGULATION OF P.D. IN MULTIPLE ARC CIRCUITS.*

BY E. P. ROBERTS.

Preliminary Note.—Since writing that which follows this paragraph, Prof. Crocker's criticism has appeared. That which Prof. Crocker states is certainly correct, although the writer is inclined to think that he puts somewhat too much stress on the omission, in the article of October 13, to state that the equaliser bar method was successful in practice after having made the statement that it is correct in theory. From the standpoint of the criticism the point is well taken. The article was intended to deal with errors in a practice which is daily followed by engineers in good standing, and the degree to which the error is injurious, and it was not intended to deal with other methods, though, in the light of Prof. Crocker's criticism, the facts which he states could wisely have been incorporated, and the writer advises that such be done by the reader.

It was an unexpected pleasure to the writer to find that his note entitled "Relation between Line Wire Losses and the Over-Compounding of Dynamos," published in the *Electrical World*, October 13, was considered worthy of an editorial notice, and also to find it considered by the *Engineering Magazine*; and, in addition, to receive a number of personal enquiries relative to the subject. The *raison d'etre* of this article is that both personal and editorial criticisms and comments have led the writer to believe that the following notes may be of assistance to those who have not studied the maintenance of constant P.D. at the translating devices of a multiple arc circuit.

An article by the writer of this paper was printed in the *Electrical World* of March 3, showing various systems of wiring for M. A. circuits, and their comparative advantages as far as even distribution is concerned. The usual system for a plant for general distribution is, as shown in Fig. 1 of this article, and for isolated plants, either as in Figs. 1 or 2.

* *Electrical World* (New York).

Digitized by Google

First.—Let us consider the inherent weakness of the system shown in Fig. 2, taking only one branch circuit, and, for convenience sake, considering that we can obtain a wire to give just the line drop indicated at full load. If it be decided to lose four volts from A to D and return, and one volt between C and D, and also between D and E, and not over 100 volts is to be allowed at when D at full load and 20 amperes flow across at C and at D and E, we will have at C and E 99 V. and the R of D to C and of D to E ·05 and of A D B—·06⅔ and the V. A. at A B 104 V. If the P.D. at A B be constant, the condition of greatest rise of P.D. at the translating devices is when the load is lightest, and if ·5 ampere only be used and be taken off at D, and then at P.D. at D rises to 103·97. This is the one extreme case, and how nearly it will be reached depends upon the conditions of the case and the care and skill of the designer. If, then, the P.D. is to remain constant at D, that at B must have a range of from 100 to 104. It is evidently impossible to have C, D, and E at the same P.D., and the practice is to have the loss between them small and put the loss in the feeder. If such is done, evidently the P.D. at A B must be capable of regulation.

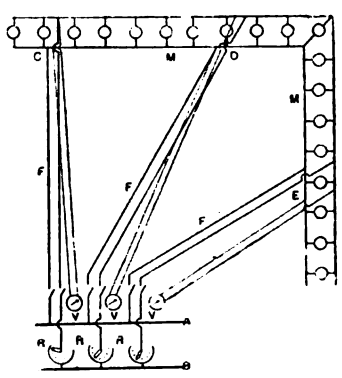

FIG. 1.

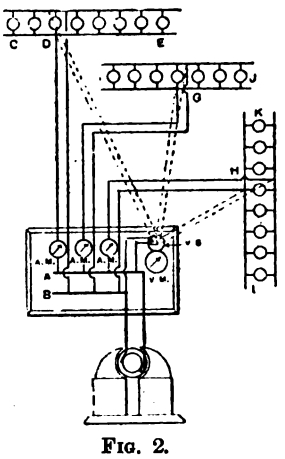

FIG. 2.

Second.—Let us consider the case of several such circuits from a constant source (see Fig. 2). Evidently, if any one branch is fully loaded, another one at half load, and another one at very light load, the P.D. at the source can only be regulated to be that which is correct for some one circuit. In order to make the average P.D. correct, probably the circuit half loaded would be chosen, if any choice be made, and if there exists means for determining the conditions and the adjustment thereto.

Third.—From the condition of Section 2 arose the design of the feeder and main system shown in Fig. 1, consisting of a number of feeders, serving one system of mains, of voltmeters to indicate the P.D. at the junction of feeders and mains, and of resistance to cut into the feeders to maintain either constant P.D. at the junction, or to have the same lowered when the C in the feeder lessens. Constant, or almost constant, P.D. is maintained at the 'bus bars A and B. The amount of R was found to be large and bulky, and the manipulation, in large plants, a source of considerable difficulty.

The next step was to employ a large number of feeders and a supplementary source of P.D. greater than that generally needed. When the P.D. at any feeder end becomes high the feeder is cut out; when low, it is thrown into the high P.D. 'bus bars.

The next improvement was to increase the P.D. by a "booster," and is the method employed on many alternating as well as direct current circuits.

Fourth.—The system described in Section 3 necessitates apparatus and attention not usually obtainable for isolated plants, but the general principle remains the same, and an isolated plant has before it a choice of evils as has a larger plant, and, in fact, almost every plant of any character. The isolated plant wiring must either be arranged as a number of circuits of the character indicated in Fig. 2, or on the feeder and main system shown in Fig. 1. If Fig. 2 be chosen, there should be indicators of current, A M, for each circuit, and voltmeter, at V M, connected at A B, and the voltage cut down either to that necessary for the least loaded circuit or slightly above, or means for determining the voltage of one or more distant points—preferably, one of each circuit—and the voltage adjusted thereto. In either case means must be furnished for regulating the P.D. at the source, and it is very seldom that it is wise to have such P.D. rise in proportion to the current output. Generally something less is preferable, and any automatic means should so deliver it, leaving hand regulation for the finer adjustment.

Fifth.—If only one dynamo is employed, then its P.D. should rise somewhat, but not exactly, in proportion to the current output and the line loss. If a number be employed, it is best not to have them over-compounded at all, or at most to only a very small amount, depending upon the ratio of size to total load (this was explained in the article of October 13). Also, as the E.M.F. varies according to the temperature of the dynamo, the hand control should have sufficient additional range to compensate for same.

Sixth.—Plants having only small wire losses, say, 4 per cent. or less, can be operated with a close approximation to accuracy by having the circuits carefully laid out and having quite a number, though not necessarily a "multiplicity," and when it becomes necessary to throw in additional dynamos dividing the circuits, giving some to each dynamo, and, as far as practicable, putting all the light loads on one and keeping its voltage down. When there are not many dynamos there is no trouble or complication in doing this. If, however, it be considered preferable to operate the dynamos in multiple arc, have hand control and means to determine the P.D. at the lamps, or the C in each circuit and the P.D. at the dynamo.

Whether the system of Fig. 1 or Fig. 2 is best to use for an isolated plant, depends upon the conditions of the case. The greatest load, the variation of load as a whole and in the various sub-circuits, must be considered, and also as to whether the control of each circuit from the main switchboard is desirable. Whatever the wiring system, the degree of over-compounding of the dynamos and the amount of wire losses have no fixed relation, and hand control is always advisable. If there be only one dynamo, and the load increases and decreases in all parts of the circuit in the same ratio, then, and then only, should the dynamo be over-compounded in the ratio of the line loss to total load. Even in the last case a hand regulation is advisable to compensate for temperature of the dynamo.

If more than one dynamo be used and the circuit be divided so that each dynamo operates independently, the conditions are similar to the preceding paragraph. If the dynamos be used either individually or collectively, and the series winding be not connected by an "equaliser," the over-compounding of each should be the same as that of the smallest dynamo used, which should be such that when it is operated alone and at full load the P.D. at the lamp is that desired. If the total line loss be 10 per cent. and the smallest dynamo have a capacity of one-quarter the total load, it should over-compound 2½ per cent.

Therefore, dynamos, when used as stated, should be shunt wound, or only slightly over-compounded, or connected by an equalising bar, and should always have a hand rheostat.

All other features being equally good, the man who can and does pay attention to the above considerations, produces a better plant than the man who slights them. Possibly the clients will never know the difference, but the designer will, provided he be competent, and that should count for something. If the plant be for incandescent electric lights, special care, instead of general plans, along some broad path intended to be an average and really not suitable to anything, will save the client from 1 to 5 per cent. yearly on his investment. The investor is not likely to consider the advisability of purchasing such advice when professional men relegate wiring plants to the "wireman" or the average installing "expert," admirable artisans as such men may be. Even the recently-graduated collegian with his magnificent training for the future, and his lack of knowledge of the conditions of practice, is not the man best fitted to design wiring plans, or to consider the mutual relation of the various elements of the electric light plant.

PROPOSED REGULATIONS FOR ELECTRIC LIGHT INSTALLATIONS IN GERMANY.

The Technical Committee of the Berlin Electrotechnical Society have drafted regulations proposed to be adopted in Germany in regard to the precautions to be taken in carrying out installations where powerful currents are used, so as to prevent danger from fire. The proposals are as follow:

I. Inspection Rules.

Section 1.—(*a*) On completion, and before being set in operation, all "strong current installations," or any extension of same, are to be tested by an expert. An inspection is subsequently to be made at least every two years.

(*b*) The tests are to be permitted by the owner of the installation. The latter, on the first examination, is to provide a plan of the installation, the correctness of which is to be determined by the expert, who is to certify so on the plan. A certificate of the condition is, moreover, to be made. This certificate is to contain the expert's results of the measurements of consumption, and it must state whether the installation fulfils the following safety regulations, or what alterations and improvements are necessary. The plan and certificate of the tests are to be retained by the owner.

(*c*) In the case of those installations in operation before the issue of these safety regulations, it is to be left to the expert to decide whether or how far any deviations from these rules are to be regarded as allowable.

II. Precautions for Safety.

Section 2.—*Division of the Rooms.*—The requirements to be fulfilled in strong current installations in regard to safety from fire refer to the kind and use of the rooms in which the installations are arranged. These are differentiated as follow:

(A) Engine or working rooms for electric light installations.
(B) Ordinary living, business, and work rooms.
(C) Damp rooms.
(D) Rooms where operations are carried on which are dangerous with regard to fire risks, or containing inflammable material.

A.—Engine or Work Rooms.

Section 3.—(*a*) Workrooms of electric light installations are those in which are arranged the motors, electrical machines, transformers, accumulators, main switching apparatus, or electrical measuring instruments.

(*b*) These rooms must not contain a large quantity of articles of an inflammable nature.

(*c*) The rooms are to be protected against the possible admission of explosive gases, fumes, or dust.

(*d*) Care is to be taken to provide ample ventilation where gas-pipes or batteries exist, so that an accumulation of explosive gases cannot occur.

(*e*) Bare conductors, fuses, or other apparatus carrying current, and having parts which are not insulated, are not to be fitted in places where water can accumulate.

(*f*) Regulating and switching appliances and lightning conductors which have no incombustible bases are to be separated from wooden walls by means of an intermediate fireproof medium.

(*g*) If persons other than those engaged in attending to the plant are employed in the room the following (*B*) safety regulations are to be adopted.

B.—Ordinary Business, Living, and Work Rooms.

Section 4.—*Covering of the Conductors.*—(*a*) Bare conductors are only permitted in fireproof rooms not containing inflammable materials.

(*b*) In all other cases the conductors must be covered and be protected against the access or entry of moisture either by the method of putting up (on porcelain insulators, rollers, etc.) or by waterproof coverings. Thus only waterproof insulated wires are admissible in wooden casing.

Section 5.—*Insulation Resistance.*—At the normal working pressure the current which may pass the insulating appliances to earth or to another conductor must not exceed $\frac{2}{10000}$ of the normal working current.

Section 6.—*Distance of Conductors.*—(*a*) The conductors laid on insulators must be placed at least 2cm. distant from one another and from uncovered metal parts, and at least 1cm. from the walls, or they must be securely protected by an intermediate medium of good insulating material from contact with the surroundings. These regulations apply, for instance, also to places where the conductors are carried through the walls and to movable double conductors.

(*b*) Where the conductors are particularly exposed to slight damage, they must be provided with a suitable protective covering.

Section 7.—*Size of the Conductors.*—The size of the conductors is to be calculated so that the heating effect of the current at the normal strength does not cause the temperature of the surroundings to exceed 30deg. C.

This condition is regarded as fulfilled with round wires of good copper when the current strength remains within the limits given in the following table:

Diameter in millimetres.	Section in square millimetres.	Greatest current in amperes.
1·0	·79	6
1·2	1·13	8
1·4	1·54	10
1·6	2·00	13
1·8	2·5	15
2·0	3·1	18
2·4	4·5	24
2·8	6·2	30
3·2	8·0	36
3·6	10·0	43
4·0	13·0	50
4·5	16·0	60
5·0	20·0	70
6·0	28·0	90
7·0	38·0	120
8·0	50·0	150
9·0	64·0	170
10·0	79·0	200

Conductors of less than 1mm. diameter are not admissible.

Section 8.—*Joints.*—(*a*) Joints between conductors are to be made by twisting them together and using solder, or by a method of jointing of equal value which affords satisfactory mechanical strength and a good contact.

(*b*) Branches are to be free from strain.

(*c*) The joints between conductors and apparatus are to be made by being securely screwed. The contact surfaces must afford a contact at least five times as great as the cross-section of the conductor, and where possible be tinned. Pointed terminals are not allowed.

Section 9.—*Automatic Cut outs.*—All conductors which would heat on the occasion of a short or earth circuit are to be protected by means of automatic current breakers (fuse wires, automatic cut-outs, etc.). At each place where the cross-section of the conductor is reduced, a safety appliance is to be inserted. The latter, as far as practicable, must be arranged near the branch. Twin and movable conductors must be so made safe that the normal current strength which operates on the safety appliance does not exceed five amperes.

(*b*) The current must be interrupted if it has reached twice the amount of the admissible strength, as stated in Section 7.

(*c*) The current strength at which the cut-out acts must be indicated on the fuse-wire socket.

(*d*) A fuse for a higher current strength must not be fitted in a socket intended for a smaller current.

Section 10.—*Protective Boxes.*—Fuse wires, cut-outs, resistances, and all apparatus at which sparks and great heating may occur are to be enclosed in boxes of incombustible material.

Section 11.—*Switches.*—(*a*) The switches must be so constructed that an arc cannot occur.

(*b*) The contact surfaces where the break takes place must in operation make sufficient contact to the extent of

Digitized by Google

at least two square millimetres effective contact surface for each ampere of the current to be carried.

(*c*) The heating of the metal parts by the current must not be greater than with the conductors.

Section 12.—*Resistances.*—With resistances, heating of the wires or plates must not exceed 100deg. C.

Section 13.—*Lamps.*—(*a*) Arc lamps are to be so arranged that no incandescent particles of carbon can fall.

(*b*) Arc lamp cases and the holders for incandescent lamps must be insulated from the conductors and from earth.

C.—Damp Rooms.

Section 14.—In damp rooms, where the insulation resistance prescribed in Section 5 cannot be obtained, all conductors shall be arranged on double porcelain insulators at distances of 10cm. from each other and from other objects, and the apparatus must similarly be insulated. When possible, the latter should be erected outside rooms.

D.—Rooms when Fire Risk is Great.

Section 15.—(*a*) Fuses and arc lamps are not to be placed in those rooms in which operations are carried on which involve the risk of fire, or which contain inflammable articles. Switches, electric motors, transformers, and resistances are at all events to be enclosed in a thick fireproof box.

(*b*) If explosions are to be apprehended through gases, fumes, or dust, such boxes must be rendered completely airtight.

(*c*) Incandescent lamps are to be provided with airtight outer covers.

SOME POSSIBILITIES OF THE STORAGE BATTERY.*

BY PEDRO G. SALOM.

There are few subjects that have excited more general interest and widespread speculation than that of the storage battery. From the wildest vagaries of the enthusiasts, who predict that in the future storage batteries will be so improved in capacity and efficiency that it will be necessary only to occasionally have a few cells of battery at one's house in order to supply an unlimited amount of light or power, that locomotives will be able to run hundreds of miles with a few hundred cells, and that ships will cross the Atlantic, we turn to the gloomiest forebodings of the pessimist, who can reason only from the failures and difficulties of the past to further trials and tribulations in the future. Inasmuch as storage batteries are likely to play a not unimportant part in the future development of electrical science, a proper understanding of the general principles underlying the subject may perhaps remove many popular errors and misconceptions.

A storage battery, or electric accumulator, is an apparatus for the transformation of energy. There is no such thing as storing electricity, and the current of electricity obtained from a storage battery after charging is derived solely from the chemical reactions taking place within the battery. This being the case, therefore, there is nothing mysterious about the operations of a battery, and it is self-evident that the limitations of its power must be directly proportional to the amount of material entering into its composition which is subject to chemical changes within the battery itself, although from the extravagant claims that are sometimes made for different forms of battery it might be supposed that the designer had discovered some method for creating energy out of nothing. Fortunately, we are able to measure to a nicety the exact amount of energy to be derived from a given combination of substances, and such claims, therefore, deceive only the credulous and unwary speculator. There are an infinite variety of forms of storage battery, all of which resolve themselves into two general types, in the first of which, known as the Planté type, the active material is produced by the disintegrating action of the current on a portion of the plates themselves, and in the second the active material is applied directly to or combined with the conducting supports.

A number of different materials have been used in the composition of the plates, but the modern storage battery—the one which is in most general use—consists almost entirely of lead and lead oxides, and the plates composing it are grids, in and upon which the oxides of lead have been mechanically applied.

The modern storage battery is the joint but independent invention of Charles F. Brush and Camille A. Faure, although Brush has been awarded the priority of invention in the United States by the highest court of appeal. Prior to their inventions in 1859, Gaston Planté made a very interesting and exhaustive study in what might be called the parent form of storage battery, although the real germ of the invention must be awarded to a French chemist, named Gautherot, who as far back as 1804 discovered the reversed currents obtained from plates which had been previously electrically acted upon. It was not, however, until the time of Planté that any attempt was made to store the electrical energy from an outside source by means of a battery or accumulator.

The original Planté battery consisted of plates of lead which were repeatedly and alternately acted upon by a current of electricity, first in one direction and then in the opposite one, until a certain proportion of the lead had been converted into oxide of lead and spongy lead. When two lead plates are placed in dilute sulphuric acid and their terminals are connected with the opposite poles of a dynamo, or some other source of electricity, and an electric circuit is made, oxygen is generated, through electrolysis, on the plate connected with the positive pole, and hydrogen on the plate connected with the negative pole. The oxygen attacks the plate of lead and combines with it, forming a thin coating of peroxide of lead, the hydrogen on the first charge escaping as hydrogen gas.

The plate connected with the positive pole is called the positive plate, and that with the negative pole the negative plate. If now the current is reversed and the positive pole is attached to the former negative plate, this, in turn, becomes coated with a thin coating of peroxide of lead, but the hydrogen which is liberated now at what was the former positive pole, instead of merely passing off into the air, acts upon the thin coating of peroxide formed by the original charge, and reduces it to spongy lead. The current is again reversed, the spongy lead produced by the second charge is peroxidised, and a further oxidation of the lead plate takes place. This operation is continued for a great number of times until the coatings thus formed are sufficiently large to do a useful amount of work, and the battery is then said to be "fully formed." In order to overcome this tedious operation of formation, it occurred to both Brush and Faure that inasmuch as the peroxide of lead and spongy lead were the useful parts of a battery, that if they could be applied directly to the lead plate, the plate acting in this case merely as a conductor, all the useful effect of a storage battery could be obtained at once without the necessity of the tedious process of formation, and this was the real invention in the Brush-Faure type of battery.

Brush took the oxides of lead and rammed them into grooves which had previously been made in the lead plate, while Faure took the same oxides, and, mixing them with a little dilute sulphuric acid, plastered them first on the surface of a plain sheet of lead, and afterwards into various forms of lead supports in the shape of grids or plates provided with other receptacles which would retain the active material. The oxides were then in some cases reduced to spongy lead by chemical means, or the plates put directly into circuit with the dynamo, and the oxides converted into peroxide of lead and spongy lead, after which they were ready to generate a current of electricity on having their terminals connected.

As has been said above, the current derived from a storage battery is produced by purely chemical means. If a piece of zinc be placed into dilute sulphuric or hydrochloric acid a violent action immediately takes place with the evolution of hydrogen gas, and the generation of a definite amount of heat. If, however, we connect this piece of zinc with a copper wire, the end of which is also placed into the acid, the wire becomes endowed with the extraordinary properties which are produced by what we call an electric current, and as this phenomenon appears, the generation of heat in the acid disappears. It has been found, after the most careful investigations and research

* From *Cassier's Magazine* for December, 1894.

Digitized by Google

that the electrical energy, measured in foot-pounds, derived from the consumption of a pound of zinc in a battery is exactly the same as the amount of energy in the form of heat, measured in foot-pounds—that is, produced by the burning or combustion of a pound of zinc—showing conclusively the correlation of these two physical forces.

The electrical energy derived from a storage battery is, therefore due to the electrical burning or combustion of the lead, of which its active part is composed. In the case of a lead storage battery the product of combustion, sulphate of lead, is not soluble in the acid, or what is technically termed the electrolyte. One pound of lead has a theoretical potential energy of about 0·15 h.p. But in order to utilise in a battery a pound of lead, which must be in a spongy condition, 5lb. of solid lead and oxide of lead are necessary, and even then only one-half of its potential energy can be taken out as useful work before it becomes necessary to recharge the battery. Of course, the remaining 50 per cent. is not lost, but it is retained as a surplus, like the water in a tank which is allowed to discharge one-half its contents and is then filled up again.

If, then, we know the amount by weight of spongy lead and peroxide of lead, or that of any other equivalent active material, we have an absolute means of measuring the maximum capacity of any given cell for furnishing electric energy for a given time, and thereby determining the limitations of its usefulness. The source of the E.M.F. of a battery, whether primary or secondary, is primarily dependent on the relative positions that any two elements or substances occupy in the electrical scale. By the electrical scale is meant the systematic arrangement of all elements and compounds beginning with the most electro-positive substance, and passing to the most electro-negative substance in the order of their degree of intensity with which they possess one or the other of these properties. Each substance in the scale is electro-positive to the substance immediately below it and electro-negative to the substance immediately above it; the substances at the beginning and end of the scale exhibiting, of course, electro-positive and electro-negative qualities in the highest degree.

The metals, as a rule, make electro-positive elements, and the non-metals—oxides and chlorides, etc.—make electro-negative elements; or in other words, the various chemical affinities which these substances have for each other determine the E.M.F. of the couple. This varies from the smallest fraction of a volt to about three volts, and in ordinary secondary batteries averages about two volts. In order to get any desired E.M.F. above two volts from a battery it is necessary to couple the elements in what is commonly termed "series"—that is, to have a number of them whose poles are connected to each other alternately negative and positive, which makes the E.M.F. cumulative similar to the winding of an armature, whereby the E.M.F. is increased in proportion to the number of turns of wire passing through a given field of force.

One of the most important applications for storage batteries is found in connection with electric lighting. Electric lighting with such batteries may be divided into isolated lighting and central-station lighting. All isolated installations that are now being run night and day can advantageously and economically be improved by the addition of a storage battery, and the continuous operation of a dynamo thus be dispensed with, as well as the services of an extra engineer. When plants are not run night and day, owing to the great expense which it is impossible to avoid in operating a few lamps before and after the hours of maximum load, it is necessary to use gas or other source of illumination. This is a ridiculous and unnecessary humiliation to the owners of a costly installation, when a few storage batteries only are required in addition to the plant which they already possess to make it available day or night.

When lamps are supplied direct, the machinery must have a power capacity equal to the maximum number of lamps, and since the lamps are usually needed only a few hours a day, the plant will remain idle the rest of the time. Moreover, the engine and dynamo must be of the best construction and design, steady and quick regulating, to prevent flickering or variation in candle-power. But with storage batteries the generator is not limited as to the time or manner of working, and can prepare its supply slowly, ahead of time, during the day, in the many hours at its disposal; and in addition to its requiring only a dynamo of very much smaller size, the machinery may be of much simpler and cheaper construction, for with the battery, irregularities in movement can exist without in any way affecting the quality of the light. The current from the accumulators is always uniform and regular, even while the charging current is subject to marked fluctuations. The storage battery is, in fact, an equaliser and regulator to the dynamo, beside acting as a reservoir in case of accident, liable to happen with the best machinery.

In all cases a direct lighting plant can be made complete and perfectly reliable by the addition of storage batteries, as the surplus energy, which can be stored while the dynamo is running under light load, can be utilised during the remaining hours of the day or night. With water or gas we cannot expect a reliable supply without providing facilities for storage. In the profitable and practical application of electricity we must also have a means of storing to ensure an absolutely steady and uniform current, so necessary with incandescent lighting, and also to provide against any possibility of the extinguishing of the lights by failure of the generating plant.

The problem of domestic lighting has been solved by the introduction of storage batteries. Heretofore, electric light was only obtainable in localities adjacent to a central station, but by the application of accumulators almost any power can be made available. In places where an arc circuit is already installed, the introduction of the incandescent light becomes a comparatively simple and inexpensive matter. The arc dynamos can be used in the daytime to charge the batteries, and at night to supply the arc lamps, while the stored electrical energy is used to supply the incandescent lamps.

As an accessory to direct lighting in mills or other manufacturing establishments, hotels, office buildings, schools, institutions, and public buildings, the advantages of the use of storage batteries are too apparent to admit of argument. They furnish light when the power is shut down (which is usually at six o'clock) for office work, watchmen, storerooms, and warehouses, for repairing and rearranging machinery, boilers, engines, shafting, etc., which in many cases has to be done at night. They will also furnish power for running electric motors when other sources of power are stopped, as at night, or on Sundays or holidays.

The advantages to be derived from the use of storage batteries in an isolated electric light installation when once fully recognised and appreciated by electrical engineers will render their introduction well-nigh universal. They may be summed up as follows: Light and power on tap at all hours of the day or night; the ability to add incandescent lighting to an arc system already installed; increase in life of lamps due to perfect regulation of the current, thus effecting a great saving in lamp renewals; as an auxiliary to direct incandescent lighting, where it is not possible or practical to keep the generating machinery in continuous operation; ease of manipulation and freedom from annoying breakdowns and other mechanical irregularities; the battery may be charged from either arc or incandescent circuits by the introduction of proper automatic safety switches and rheostats; the utilisation of the current for many household conveniences, such as the running of fans, sewing machines, clocks, electric bells, pumps, etc.; economy obtained by dispensing with an extra engineer for nightwork, and by obviating the necessity of running a large engine and dynamo for lighting a few lamps during the day or night, or before and after the time of maximum load.

The ideal electric lighting for country homes is to be able at all hours, night or day, to turn on one or the full quota of lamps, with a never-failing supply of electricity, without the annoyance and expense of running the generating plant all night. This can be obtained only by the use of storage batteries, in which sufficient energy is stored during the day, according to the amount required for the 24 hours. Where steam power is not available, or is otherwise objectionable for charging batteries, a reliable, safe, and economical power is a good oil-engine, which is so simple to

Digitized by Google

manipulate that an ordinary workman or gardener may be educated in a few days to safely operate and attend it.

One important point to be remembered is that with a storage battery the generating machinery need be only a fraction of the size required for direct lighting. Inasmuch as the work done in an isolated plant does not average more than three hours per lamp per day, or, say, for a 100-light plant, 300 lamp-hours, it is manifest that a 50-light dynamo running six hours will accomplish the same work through a storage battery as a 100-light dynamo running direct.

The advantages of using storage batteries in central-station lighting may be briefly summed up as follows: they effect a substantial saving in operating expenses, they increase the factor of safety, they permit of a material extension of distribution without increasing the size of the power plant. Since the question of economy is largely the determining factor in considering the advisability of introducing a battery, let us examine more at length the means by which economy may be effected: (1) by taking care of sudden and excessive load when all the generating machinery is taxed to its utmost extent; (2) by dispensing with one shift of labour in taking care of the entire minimum load; (3) by permitting the operation of large units exclusively; (4) by operating all the units at their maximum load, and hence their maximum efficiency.

Owing to the peculiar nature of electric lighting it frequently happens that the number of units generated at the maximum load is not more than a few per cent. of that of the total average load, and the total load is only a few per cent. in summer, and rarely above 40 per cent. in winter of the total possible output of the plant.

The first requisite in determining whether a battery can be advantageously introduced in any given central station, and, if so, what its size or capacity shall be, is to have diagrams of the load curves. The next important factor is the number and size of the units employed at the station. From these data can be determined what has very appropriately been called the load-factor, and then it is simple to calculate the size of the battery required to give the most economical operating results. Once the size of the battery determined we can calculate the saving effected (*a*) by dispensing with a night shift; (*b*) by diminishing the consumption of coal for a given output; (*c*) by the saving effected by operating a few large units of one size, instead of a number of small units of various sizes; (*d*) by the saving effected in operating each unit at its maximum efficiency; (*e*) by the additional revenues from increase of total output taken from battery at time of maximum load.

As the item of labour in small stations is frequently as high as 25 per cent. of the operating expenses, the saving effected by dispensing with a night shift is not inconsiderable. By operating exclusively large units there is also a material saving both in labour and the much higher efficiencies of large over small units. Again, as the coal bill is the largest item of expense, amounting in some cases to 50 per cent. and over of the total operating expenses, any saving effected in this item is of paramount importance, and is reflected at once in the decrease in operating expenses.

The question of mechanical efficiency with varying loads has not been as carefully studied with each type of engine as its importance deserves, but Prof. W. Cawthorne Unwin has shown that the decrease of mechanical efficiency for light loads has a serious effect on the economy of working with a variable load, and that with a load varying from 100 to 25 per cent., the efficiency decreases from 85 to 40 per cent. While it is impossible to say in a general way what the exact saving would be from the introduction of a battery of sufficient size to permit of the operation of all the units at maximum load (since the load is not the same in any two central stations), the results prove that in central stations equipped with storage batteries the operating expenses are diminished as much as 30 per cent.

As to the factor of safety, in case there is a derangement or breakdown of the generating machinery, or where the steam pressure cannot be kept up to a sufficiently high point to operate all the units at maximum load, the elasticity of a storage battery permits of an immediate discharge rate enormously in excess of its normal rate. In other words, a battery designed for a given output could in emergencies be safely called upon for one half-hour or more to deliver a current three times as great as that for which it was designed.

This is a question of vital importance, as in any direct system of transmission there is always the liability of a derangement or breakdown of one of the links in the chain, whereas in a station equipped with a storage battery the manager can depend on the battery to take the load of an individual unit until such time as the derangement or breakdown can be remedied or repaired. Moreover, it frequently happens where the business of a station has increased since the original introduction of its generating machinery, that the boiler capacity at maximum load is so taxed that it is difficult to maintain steam pressure sufficient to operate all the units at once. In such a case, if a battery is employed, recourse may be had to the battery until such time as the engineer shall be able to keep steam up to the required pressure.

As regards distribution, it is evident that when a central station, for example, has supplied the demand within a given radius of economical distribution, and a demand arises for electric light or power immediately adjacent to and outside of this given radius of distribution, it is possible to supply this demand by having sub-stations of storage batteries which may be charged by a special wire at comparatively high pressure during the day, thus increasing the average load of the central station. At night the current may be distributed from the sub-stations at the regular pressure, thus enabling the central station to materially increase its revenues without increasing its original power plant. There is an economy also effected in this method of distribution by decreasing the size of the feeders to the outlying districts. This is accomplished by being able to charge the batteries used at a comparatively small rate for 10 or 12 hours, whereas by lighting direct the feeders would have to be large enough to carry the entire load of the sub-station at its maximum output, which might last only for two or three hours.

Besides the saving effected in operating expenses, the use of a battery may be made to yield additional revenues in proportion to the amount of current supplied to the circuit over and above what could be supplied by the direct system, at the time of maximum load, without increasing the size of the power plant.

From what has been said above, it is evident that central-station lighting is one of the most important fields of usefulness of the storage battery, and one which has hardly yet been touched upon.

HINTS TO BEGINNERS IN THE DRAWING OFFICE.

BY ERNEST SCOTT.

As more and more importance is being attached to mechanical drawing in engineering establishments, it behoves the apprentice or pupil to be well acquainted with drawing-office work and routine, otherwise his chances as an engineer may be retarded.

To have a good set of instruments is a very important matter, as those of inferior workmanship never wear satisfactorily. On the other hand, a good set of instruments improve by use, working more smoothly as they get older. The best test for compasses and dividers is to see that when the legs are drawn apart with an even tension there is no fluctuation in speed. It may be mentioned that beeswax rubbed into the joints of compasses will greatly improve their working. Instruments with needle points are best, but the needle should have a shoulder to prevent its making too large a hole in the paper.

The box of instruments should contain a pair of large compasses, with needle points and lengthening bar, pen and pencil legs, small compasses having needle points, with pen and pencil legs, a pair of dividers, a drawing pen, and a scale of chords. The framed set squares are much better than the plain wood or vulcanite ones. The pencils that will be found most useful are those marked H or HH, or No. 4, and should have their points sharpened, chisel fashion, the flat face being placed against the edge of the T or set square. The compass pencils should be sharpened in a similar manner. These may be kept in good order for some time by sharpening them on a strip of fine glass-paper or a smooth file. The edges of the set squares should not be less than 1-16in. thick, as the ink is liable to run out of the pen on to the set square if they are any thinner.

Those who are not inclined to give a good price for a complete set of instruments by a good maker will do well to procure

Digitized by Google

their instruments separately, and have a case made for them when they have obtained the full number; until then they may be kept in washleather, pockets being provided to prevent the instruments coming in contact with one another when folded up. Second-hand instruments are often very disappointing, as large numbers of instruments are manufactured to be sold as second-hand.

Bow pen and pencils are the most useful instruments, and the writer has seen splendid work done with them alone, the bow pens being opened out flat and used as a ruling pen when necessary. The ruling pen should be ground fine, and the inside faces of the nibs close to the extremity should be as nearly parallel as possible. The instrument is held between the thumb and first or second fingers as nearly as possible at right angles to the drawing. In using the dividers, place the forefinger on the head, and move the legs with the thumb and second finger; and in dividing distances into equal parts, it is better to hold the compasses by the head as much as possible after they are once set to the required dimensions. In taking off distances by the dividers, first open them a little too wide, and then bring them back to the point required by adjusting with the little screw and loose leg. The cheapest and one of the cleanest scales to use is that made of paper; it should, however, be varnished on each side with two coats of the best white shellac made with alcohol. They should have from 10 to 14 hours to dry before using. When the scale gets worn with the points of the dividers and compasses, revarnish. These paper scales are always sold unvarnished; why, the writer cannot understand.

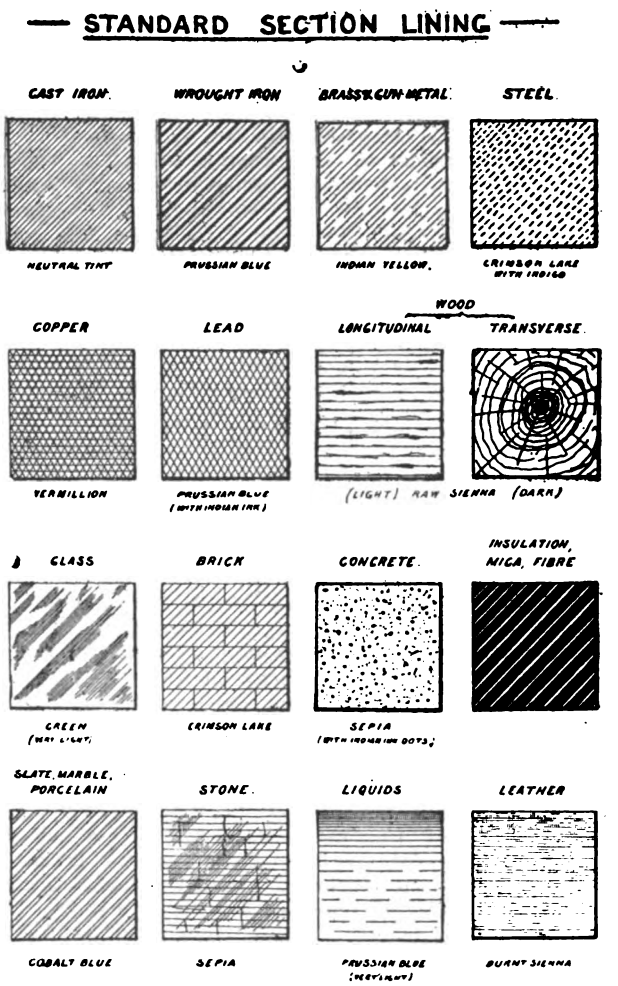
The so-called "universal" scales are a delusion and a snare, and sure, sooner or later, to cause an error. One scale on each edge is quite sufficient. An ordinary steel foot rule, or double-up boxwood rule, is best for full size, and a boxwood scale rule fish-back section, 18in. long and marked with half size, 3in., 1½in., and 1in. to 1ft., is very useful. The remaining scales—¾in., ⅜in., ¼in. and ⅛in. to 1ft.—requiring very fine dividing, should be cut on an ivory rule 1ft. long. Other scales—such as 2in., 3-16in., etc.—can be drawn on paper as required or along with chain scale, and millimetre scales can be bought very cheaply. Not being often used, a coating of varnish will preserve them for a long time.

The reservoir drawing pen is a very useful instrument where a good deal of section lining has to be done, or where, as with diagrams, the lines are very thick. The pen can be charged with ink for half an hour's continuous work. Transparent set squares have been introduced recently, and being thin, well glazed, and slightly flexible, they have all the advantages of the best vulcanite set squares without the disadvantage of readily collecting the dirt. As a result of their transparency, they do not obstruct from view the lines, etc., on that part of the drawing over which they are being used. The polish on the underside (the side next to the paper) of T-squares should be sandpapered off before being used; if this is not done, it will only wear off on to the paper and spoil the drawings.

The kind of work a beginner will have to do on commencing depends on his previous training. As a general rule he is always given tracing to do first, and it has the advantage over drawing in that blunders will be much more apparent. Moving the T-square or set squares over newly-inked lines is one of the first points to avoid. A slight pressure of the hand on the head of the T-square, so as to raise it about 1-16in. off the paper as it is moved, is the way to overcome this. One of the most effectual means of keeping white paper clean, and preventing the dust that collects on it from being ground in by the T-square, is to rest the hand firmly on the head of the T-square; it will be found that the square can be balanced so as to touch on the paper at the opposite end only.

In inking in and tracing, the circles and curves are put in first, as it is much easier to join up straight lines to curves than *vice versâ*. A tracing may be finished off in various ways. If it is for sending away it should be coloured, but if it is to be used as a negative for taking blue or white prints, the sections should be cross hatched. Cross hatching or sectioning requires a considerable amount of practice to make it appear effective and neat, and it also consumes a large amount of time. Patent drawings and illustrations for books, catalogues, etc., always require doing this way.

It is usual to represent the parts in section by lining them in various ways, and an endeavour has been made (at the Sibley College of Mechanical Engineers, Cornell University, U.S.A.), by Prof. R. H. Thurston (*vide American Machinist*, April 9, 1887) to standardise a system of section lining. The following will, however, be found to be almost universal. It is fairly comprehensive, and possesses the merit of being simple and easily remembered. Chilled and hardened surfaces might be indicated by stopping the section lines short of the edge. A striking appearance may be quickly given to a drawing or tracing by shade lining, or making light and heavy lines. The lines having first been drawn of uniform thickness, the direction of the light is assumed to fall on the object from the upper left-hand corner—that is to say, the shadows, if any, fall on the right hand and lower edge of all the parts being drawn. The heaviest lines on objects should therefore be those on the lower and right-hand edge of each part. It is not necessary that the contrasts between the lines should be very marked. Beginners generally make the heavy lines too thick, and where the corners join into the circles the effect is not good unless there is considerable experience beforehand. An excellent little instrument for this work is the duplex ruling pen. By simply setting two small screws, all the fine and shade lines can be done together, and always of the same thickness.



After a few tracings have been inked in, an attempt should be made to design a suitable border. They are easily and quickly made, and for illustrative tracings sent out on tender work have much to do in giving them a finish. Too much elaboration should, however, be avoided, for fear the border lines show more care than the drawing. The writing or printing often makes all the difference between a good and badly finished drawing, and a few hints may not be out of place. Artistic lettering may be learnt by purchasing a book giving examples of the different classes of letters, or by obtaining handbills which have the larger form of letter on them, and tracing these for a few days. The student will be surprised to see how easy it is to acquire the correct shape of the letters. Plain block letters are very useful, and they can be modified by shading. Of the various forms, the italic letters are easiest to acquire, and at the same time present a very striking appearance, the letters a and g being the most difficult. If the drawing is symmetrical, the title should have as nearly as possible the same symmetry, and should be printed in the centre underneath—the drawing or tracing number being at the two bottom corners, and the drawer number at the top corners. The lettering of a drawing should have a close resemblance to both the drawing and border; therefore, if the two latter are plain the lettering should also be plain. The size of the title should be in proportion to that of the drawing, the largest letters not being more than 1-30 of the height of the drawing. The name of the object and the customer should be the largest, that of the engineering firm doing the work being much smaller.

Stencil plates are much used in printing letters and words that are constantly required, such as plan, elevation, section, north, full size, half size, etc., numbers 1 to 9, and the letters of the alphabet in two or more sizes. The stencil brush should be moderately stiff, and the ink rubbed into it on a piece of old leather belting 4in. square, set in a recess in a convenient-shaped piece of wood, the brush being gently dabbed, not rubbed, on the stencil. Stencil plates are best made of copper, this metal being far superior to brass, as it lies closer to the paper. This close contact is important, as it prevents the hairs

Digitized by Google

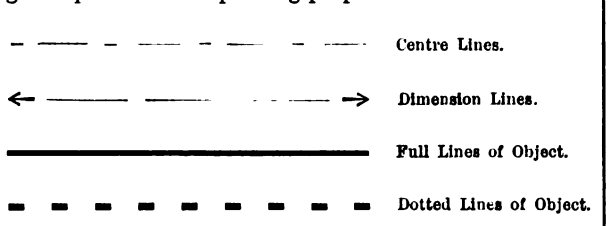
of the brush getting under the plate and producing uneven edges. When the plates have been in use for some time, the corners are apt to get clogged up with ink; this can be removed by leaving them for a few minutes in hot water and then carefully wiping. If the plates become cockled, they may be flattened by pressing between two hard metal surfaces. When being used the stencil plates should be held firmly to the paper by the fingers of the left hand, the right being used for the brush.

To prevent tearing the edges, the plates should be turned up $\frac{1}{8}$in. all round. Where separate rubber stamps are used for the numbers or letters, instead of stencils it is a good plan to put the stamps through holes in a small wooden box so that the rubber rests on an inked pad of felt at the bottom. In this way they are always ready for use, and there is no inking-pad to get lost, the whole being self-contained. Rubber stamps are a little more expensive than stencils, but they have the advantage of never getting clogged with ink, and are much handier to use. Lithographic ink with the addition of a dryer may be used for stencilling on tracing cloth, as it gives a deep black impression which prints well, and it will not rub off.

Indian or Chinese ink is always used because it gives a dense black line, and being free from acid it is not injurious to the instruments. The genuine ink as imported from China varies considerably in quality. The best quality may be fairly ascertained by breaking off a small portion; if the quality be good it will show a prismatic-coloured fracture and not a dull, black appearance. The mixing of Indian ink is not a thing to be despised, and the beginner should rub ink until he can make it in a clean manner. The ink must be made moderately thick, so that the pen on being shaken will retain it about 3-16in. up the nib, and should be used directly after mixing, for if redissolved it becomes cloudy.

It is found in practice that on a brush being passed over the ink lines in colouring a drawing that the lines wash up, but this may be avoided as follows. It is generally known in photography that animal glue, with potassium bichromate, after being exposed to the action of sunlight, becomes impermeable to water. If, therefore, in rubbing the Indian ink (which has been found to contain, according to the latest investigations, not vegetable, but animal glue, as binding material) one uses a diluted solution of potassium bichromate, containing about 2 per cent. of this substance, the lines, after exposure to sunlight for one or two hours, will not become blurred if gone over with water-colours. The water used for mixing colours (lithographic ink, Indian ink, etc.) should really have been previously boiled to get out the chalky matters, but this is not generally done. If ink is required for sun printing purposes, it should be mixed as thick as is consistent with free running, and should have a small quantity of chrome yellow or burnt sienna mixed in with it, as these colours stop the actinic rays to a large extent. For this reason the above colours should be used very sparingly, or not at all on tracings which are intended to be sun-printed at any time. Of course, no colour will show on the sun print, but a wash of neutral tint is useful for showing up certain parts, sections, etc.

One of the great advantages of prints with blue or black lines on white ground is that the print can be coloured afterwards. All the lines should be in black, and made as follows, if the tracing is required for sun printing purposes:



For inked-in drawings and for tracings which are not required for sun printing purposes the lines are drawn in their respective colours, thus:

Red for centre lines.
Blue for dimension lines.
Black for full and dotted lines of object.

Written figures and letters should all be in black, and machining lines shown in red. A blue or red line can be drawn over a black one by mixing the blue or red colour with a small quantity of Chinese white. The white gives a dense dead colour which prevents the black showing through.

The glaze on tracing cloth is difficult to work on. It can however, be removed by rubbing over the surface with chalk. Precipitated chalk at 2d. a pound is cheaper than buying blocks of French chalk and scraping off what is wanted each time a tracing has to be made. A special duster or brush should be set aside for this work. Ox-gall mixed with the ink or colour will make it run and adhere better; it should, however, be used sparingly. Fractions of an inch should not be written in grocer's fashion—thus, 1/16, but like this, $\frac{1}{16}$—and the ticks feet (′) and inches (″) should never be omitted. All working drawings should be fully dimensioned, and the dimensions as far as possible be in that position required for reading the title. Any exceptions to this rule to be placed so as to be read when looking from right to left of the drawing.

It is as well to have one standard size for all drawings—double elephant or imperial—and also a standard size for all sketches, say 8½in. by 1ft. 1in. These sizes should never be deviated from, for although some drawings may be rather crowded and others just the reverse, they are much easier to find in the drawers when all one size and the titles and numbers lying just above one another.

The best plan of supplying the drawing pen with ink is by means of an ordinary pen nib, this method keeping the outsides of the drawing pen clean. If, after laying the pen down for a moment or two, the ink at the point dries and won't run—it may be started by touching it on the skin; this plan seldom fails so long as there is ink between the nibs. There are several liquid inks on the market put up in bottles, Wolff's and Higgins's being about the best. Their great advantage is that the ink is just as good at the last drop as when first opened, and also always of the same intensity of blackness—a very good feature on an "inking-in" job taking several days or a week to complete. The cork should be fitted with a pointer which dips down nearly to the bottom of the ink, and with this the pen or compass may be supplied without wetting the outsides of the nib, as mentioned above. Before putting the pen away it should be carefully wiped, and if the ink has been allowed to dry between the nibs it may be removed by softening in a little water and wiping directly afterwards.

The following are the colours generally used for representing the different kinds of metal, etc. They are not so much intended to represent the material used as to distinguish one material from another on the same drawing:

Initials in general use.	Material.	Colour.
C.I.	Cast iron	Neutral tint.
W.I.	Wrought iron	Prussian blue.
M.C.I. ...	Malleable cast iron ...	Purple.
S.	Steel	Crimson lake with indigo.
C.	Copper	Vermillion.
B.	Brass	Indian yellow.
G.M.	Gunmetal	Indian yellow.

Material.	Colour.
Phosphor and aluminium bronze	Gamboge with crimson lake.
Lead and white metal linings for bearings	Prussian blue with Indian ink (very light).
Soft wood, as deal, pine, etc.	Gamboge with small amount of raw sienna.
Hard wood	Raw sienna with small quantity of gamboge.
Oak and teak	Vandyke brown.
Brickwork	Venetian red or crimson lake with sienna.
Ebony, ebonite, and vulcanite	Indian ink (dead black).
Indiarubber	Burnt umber and neutral tint.
Granite, freestone, stone	Sepia.
Concrete	Sepia, with Indian ink dotted on with a bit of cloth.
Earth and clay	Burnt umber.
Water	Prussian blue, with lining (very light).
Oil	Indian yellow and Prussian blue, with lining.
Porcelain, slate	Cobalt blue.
Glass	Very light green.
Leather	Burnt sienna.

The grain of wood may be shown by streaks of burnt umber. In electrical engineering drawing offices it is usual to represent all insulation by a dead black, notifying in writing whether it is mica fibre, longcloth, ebonite, indiarubber tape, etc. A steel colour (crimson lake and indigo) is sold by Halden and Co., Manchester. For tinting large areas a large brush is used, and the colour should be light. If wanted darker two or three coats are put on, each after the other is dry. In proceeding to lay on the colour, tilt the drawing slightly and start at the top, so that the colour will run down. After taking the first stroke with the brush, the second stroke should immediately follow into the moist edge of the first line. This is important, because wet colour may be easily united to a moist edge, but not to a dry edge. It is well to have a dry brush handy to take off superfluous colour if necessary.

All sections are given twice the depth of colour that the elevations, etc, receive—that is, they should have two washes where the elevation gets one—care being taken to allow the first wash to dry before the second is put on. If this is not done it is apt to be blotchy. Cloth and paper tracings are coloured on the back: there is then no fear of the lines washing up.

Digitized by Google

All material such as charcoal iron, stick or rod brass, etc., should be gone over with the same colours that are used for wrought iron, brass, etc.; but a special note should be made in writing on the drawing that such and such a detail is made of "well annealed charcoal iron," or "three-quarter drawn rod brass," as the case may be. For shading drawings, Indian ink mixed very thin is best. Sable hair brushes are generally used, and there should be a brush at each end of the handle, one being larger than the other. The small brush is supplied with colour, and the large one thoroughly moistened with clean water. The colour which represents the dark portion is then laid upon the drawing with the small brush. Before it is dry, however, the moistened brush is drawn down the line to be shaded off, and then another nearly dry brush is drawn along the outer edge to take up any surplus water. If darker shades are required, the first coat should be allowed to dry (this is very important), and the above operation gone over again. After shading, go over each part with its characteristic colour. If the drawing has to be varnished afterwards, it is necessary that a small quantity of alum should be added to the water-colours before using. The varnish should be made of 2oz. of Canadian balsam and 4oz. of oil of turpentine dissolved together whilst warm. Gamboge should not be used alone on tracing cloth, as it smudges badly. Chrome or Indian yellow or vermillion is much better. Indian ink and colour may be removed from tracing paper by the application of a little soap and water, carefully removed with a clean brush and blotting paper. Indiarubber may now be bought very cheaply, but a piece taken from an old air-pump valve gives very good results. To clean a drawing after colouring, it should be gone over with bread, because indiarubber disturbs the colour. For very highly-finished shaded drawings it is customary before starting drawing to take off the surface of the paper with fine glass-paper. If this precaution be taken, any erasure that may be made before the colour is put on will not be noticeable, whereas if this is not done the colour comes out blotchy, and several days' work may be spoilt in a few minutes.

If duplicate drawings are wanted on Bristol board or drawing paper, considerable time and labour may be saved by using a printing frame as follows: the drawing to be duplicated is laid next to the glass with the drawing facing the operator, and on this is placed the blank sheet, the frame being so arranged that a strong light falls on the underside of the glass from a window or lamp. It will then be found that the lines of the drawing show through the blank sheet, and they can be inked in straight away. Jobs can be done in this way in an hour, including time spent in fixing up, that would otherwise take the greater part of a day. This method is also useful for making a very neat coloured drawing, as there are no pencil lines to be rubbed out, and very smooth hot-pressed paper may therefore be used.

For mounting drawings, paper tracings, sun prints, etc., get a board with a good surface. Stretch the linen or calico (which should be cut to leave 2in. margin) flat on the board, tacking it down all round, the tacks being close together and care taken not to pull the edges of the cloth; it should then be well coated with strong size and left until it is almost dry. The drawing to be mounted and the cloth should now be well covered with paste, to which a little gum arabic has been added, the paste being worked well into the cloth. This will be done best if done at two operations, leaving the first coat about five minutes to soak. Directly after applying the second coat, place the paper on the linen and work from the centre outwards with a sponge, squeezing out all the superfluous paste. It will take at least eight hours to dry thoroughly, even in warm weather.

To mount drawings, take a sheet of Whatman's paper and turn up 1in. all round, slightly damp the paper with a soft sponge, then glue the edges and turn them down on to the board, putting weights at the corners and the middle of each side, the edges being well rubbed down and allowed to dry for at least three hours. The paper in drying contracts slightly, so that it lies as tight as a drum on the board and is very pleasant to work on. Of course for ordinary jobs it is not usual to go to the trouble of mounting. Pencil lines may be fixed by going over them with size, skim milk, or water starch of such strength as to form a jelly when cold.

It is necessary that the beginner should as early as possible make himself acquainted with the system of the particular drawing office he happens to be in. The mode of procedure in preparing drawings, entering them, and filing away varies with each office, and although some of it may seem to him rather tedious, he should remember that system is necessary in order to define the duties of each individual and to fix the responsibility should anything go wrong. It is also most necessary to preserve uniformity of practice with changing draughtsmen.

Before commencing a drawing, the conditions which *must* be complied with and the conditions which may be varied if necessary should first be set down mentally or in writing, all problems being also solved before commencing by calculation and hand sketches. These two simple rules if adhered to will save much valuable time in unnecessary drawing and rubbing out. The principal fundamental formulæ and constants should be committed to memory, and in the very near future a man who is not perfectly at home in the use of the slide rule will be at a discount. After one or two sizes of a new series of machines have been made and tested, dimensions of the other sizes to complete the series may be quickly arrived at by curves on squared paper. It will generally be found that the nearest whole number to what the curve gives will not be far wrong.

In making illustrative drawings for tender, a good deal of time may be saved by as far as possible keeping to standard with regard to the scales employed, so that combinations may be made by tracing. There is no advantage in laying down a small engine dynamo or pump to a large scale merely to fill up the paper. The following are suitable scales for the different classes of work:

¼in.	to 1ft.	for buildings.
½in.	,,	for foundations and pipe arrangements.
1in.	,,	for general drawings of machines.
3in.	,,	and full size for details.

With regard to the scale for general arrangements, it may be mentioned that Messrs. Willans and Robinson's drawings and lithos, which are more widely distributed in the electrical engineering trade than those of any other firm, are all drawn 1in. to 1ft. These particular engines have had such a run that dynamo makers had in many cases to follow suit, although 1½in. to 1ft. is generally considered to be a better scale for arrangements.

Although neatness and accuracy of drawing and projecting is desirable, it only represents a small part of a draughtsman's work, and if it is obtained with the expenditure of an undue amount of time, and does not carry with it, practical knowledge of shop needs and processes, it ceases to be a virtue. The writer has come across men calling themselves draughtsmen having an exceedingly limited knowledge of shop processes. Such men cannot be left to their own resources for a moment, although at the same time they are able to make a very pretty drawing. They therefore rarely get beyond tracing and tender work. The drawing office is undoubtedly one of the best schools for the young mechanical engineer, provided he goes at his work well trained in the principles and fundamental laws of mechanics, and works with a combined purpose of making a good machine as well as a good drawing.

In making shop drawings the draughtsman has to be continually asking himself, "Now, if I had to do this work in the shop, what information should I want?" and he should then proceed to put down just that amount of information. He should send out the drawings so that he has not to be asked by either foreman or leading hand how this or that part has to be fitted together. I would impress on those just beginning the importance of drawing everything correctly, properly projected and to scale. I have come across men who systematically draw incorrect projections and sections, and who, when remonstrated with, said "they did so in order that the workmen would understand the better how to mark it out." There never was a greater mistake; much better take it for granted the workman knows as much as yourself (he probably knows considerably more), and give him the best work you can do. A part section here and there and not too many dotted lines will tell him all that is needful. Thanks to our technical schools and evening classes, a considerable change has come over our artisans since James Nasmyth described mechanical drawing as the "alphabet of the engineer—without a knowledge of it the workman is a 'hand,' with it he indicates the possession of a 'head.'"

In connection with this I should like to mention that Cryer and Jordan's "Mechanical Construction," Tomkin's "Machine Construction," and Angel's large book and plates on "Geometry," are the best books I know of for a beginner; and he also cannot do better than attend the nearest evening technical school and get the "first advanced" science and art certificate in machine construction and drawing. For although science and art certificates are at a discount at present, I feel quite sure that that particular examination is a very fair test, and the holder of such a certificate will stand a better chance with the next generation (if I may use the word) of leading draughtsmen and managers.

PHYSICAL SOCIETY.

At an ordinary meeting on the 14th inst. **Prof. W. E. Ayrton** and **Mr. H. C. Haycraft** communicated a paper on a "**Students' Simple Apparatus for Determining the Mechanical Equivalent of Heat.**" Mr. Haycraft, who read the paper, explained that the object at which the authors had aimed was the construction of an apparatus which could be placed in the hands of junior students, and by means of which a result correct within 1 per cent. could be obtained without the introduction of troublesome corrections. The method employed is the electrical one, and the measurements to be made are (*a*) the value of the constant current passed through the resistance, as given by a direct-reading ammeter; (*b*) the average value of the P.D. between the terminals of the resistance, as

Digitized by Google

given by a direct-reading voltmeter; (*c*) the mass of water heated plus the water equivalent of the containing vessel, resistance coil, and stirrer; (*d*) the rise of temperature of the water; (*e*) the time during which the current is passed. Of these the measurements (*a*), (*b*), (*c*) can be effected without the introduction of an error anything like so great as 1 per cent. The case of (*d*) and (*e*) is different. The rise of temperature to be measured with accuracy should be fairly considerable, and the same remark applies to the time of heating as measured by an ordinary stop-watch. At the same time, if these two quantities are made unduly great, there will be too great a ratio of heat lost to heat generated during the experiment. The authors consider that with a given amount of electrical power available the best conditions will be obtained by making the percentage accuracy of the temperature measurement the percentage accuracy of the time measurement, and the percentage of generated heat lost by surface cooling equal. Hence, they determine the mass of water to be used, and the time of heating which may be expected to give the best results. The immersed conductor is a strip of manganin about 0 25in. wide, 0 03in. thick, and 5ft. long, which is bent into a series of zigzags, so as to form a kind of circular gridiron; the successive portions of strip lying all in one plane and the whole being held rigid by a strip of vulcanised fibre, to which each portion of the strip is screwed. Another precisely similar grid is placed 3in. below the first, and the two are joined in series, and are mechanically connected together by thin vulcanite pillars. The water is contained in a glass beaker of just sufficient diameter to take the framework of manganin strip. This latter exposes a considerable surface (about 400 square centimetres) to the water, and is moved bodily up and down during the experiment, thus constituting an efficient stirrer. To allow sufficient freedom of movement, electrical connection is made by means of very flexible leads, each made up of about 210 thin copper wires. The results obtained by students for the heat equivalent of the watt-second have an average deviation from the mean, if several experiments are made, of less than one-half per cent.; and they agree with the best standard determinations within 1 per cent.

Mr. Griffiths thought it inadvisable to provide junior students with apparatus from which every source of error had been eliminated; they were thus led to underrate the difficulty of an experiment and the care required to obtain reasonable accuracy.

Prof. Carey Foster agreed generally with Mr. Griffiths, and deprecated the use of direct-reading ammeters and voltmeters in experiments of this kind. He thought it preferable that a student should learn to reduce instrumental readings to absolute measure for himself.

Prof. S P. Thompson dissented from the opinions expressed by the two previous speakers, and thought it was an advantage to students to have the use of direct-reading instruments.

Dr. Sumpner described a simple method which he had employed for measuring the mechanical equivalent of heat, and which depended on the heating of a stream of water as it flowed through a pipe containing the current-conductor.

Prof. Ayrton replied, and explained that the calibration of ammeters and voltmeters would be part of the work of a student at another part of his course.

A paper by **Prof. Ayrton** and **Mr. E. A. Medley**, entitled "**Tests of Glow Lamps and Description of the Measuring Instruments Employed,**" was commenced by Mr. Medley, the latter part of the paper being held over till next meeting. The object of the investigation was to find at what E.M.F glow lamps could be most economically run. Too low an E.M.F. gives a low efficiency, and too high an E M F. renders the lamps short-lived, so that there must be (for a given lamp) a certain E.M.F. which is more economical to work at than any other. It was also pointed out that, as glow lamps deteriorate and become less efficient with use, it may be an economy to discard a lamp before the filament actually breaks. The lamp is then said to have reached the "smashing point." Accumulators were used to drive the lamps, automatic apparatus being used to keep the E.M.F. constant, and when a lamp filament broke, the fact was automatically recorded on a tell-tale.

LEGAL INTELLIGENCE.

REDDAWAY AND OTHERS v. BANHAM AND OTHERS.

This case was heard last week before the Master of the Rolls, Lord Justice Lopes, and Lord Justice Rigby. It was an application by the defendants for judgment or a new trial in an action tried before Mr. Justice Collins and a special jury at Manchester. The action was for an injunction to restrain the defendants from continuing to use the word "camel" in such a manner as to deceive purchasers into the belief that they were purchasing goods (camel-hair belting) of the plaintiffs' manufacture, and from passing off their goods as and for goods of the plaintiffs' manufacture It appeared that several years ago the Lancashire Belt Company made a camel-hair belting for machinery, and called it Reddaway's camel-hair belting, and largely advertised and sold it as such, and stamped a camel upon the belting. The defendant Banham had been a workman in the plaintiffs' employment, and after he left that employment the defendants made a belting of similar material, and advertised and sold it as Banham's camel-hair belting, and on the belting itself they stamped the words "Camel-hair Belting." At the trial the plaintiffs called evidence with the view of showing that in India a person buying camel-hair belting would expect to get Reddaway's camel-hair belting. The learned judge granted the injunction claimed, and the defendants moved for judgment or a new trial.

Mr. Bigham, Q.C, and **Mr. M'Call, Q.C.** (instructed by Messrs. W. C. Chew and Sons and Hilditch, of Manchester), for the defendants, contended that the defendants had a right to manufacture belting of camel-hair and to call it by its true name, and sell it as such, so long as they added nothing to the description likely to deceive purchasers.

Mr. Gully, Q.C., and **Mr. J. C. Graham** (instructed by Mr. A. Macdonald Blair, of Manchester), for the plaintiffs, relied on the fact which had been found by the jury—that the words "camel-hair belting" had come to be understood by the public as indicating goods manufactured by the plaintiffs, and had ceased to be merely words of description.

The **Master of the Rolls** said that the action was for an injunction, and an injunction alone. The defendants, he held, had a right to imitate the plaintiff's belting, and if they were trying to beat them out of the market they had done nothing wrong. In calling the goods camel-hair belting they only told the truth. It was said that the defendants had a wrong intention—to pass off their goods as the plaintiff's. Even assuming that to be so, the law took no notice of intention in a man's mind unless it was carried into effect by a wrongful act. Therefore, as the only default suggested was the using the name, intent was immaterial. In these circumstances the learned judge ought to have entered judgment for the defendants, and the appeal must therefore be allowed.

Lord Justice Lopes said the appeal must be allowed, and **Lord Justice Rigby** delivered judgment to the same effect.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Great Yarmouth.—Tenders are invited for installing the electric light at the Town Hall, free library, and Great Yarmouth police station, for the Town Council. Particulars were given in our last issue. Tenders must be sent in by January 2.

Great Yarmouth.—Tenders are invited for the supply of 200 tons of good hand-picked steam coal, from the Clifton or Hucknall pits, delivered into the coal bunkers at the electric light station, in lots of about 30 tons per week, commencing January 15, for the Town Council. Tenders to be at per ton of 21cwt., to be endorsed "Tender for Coal," and delivered at the office of Mr. T. M. Baker, town clerk, Town Hall, Great Yarmouth, before noon on January 1.

Stockport—Tenders are invited for providing and fixing complete a fuel economiser, for the Corporation. Plans of the boiler-house, now in course of construction, together with the specification of the work required, can be seen and form of tender obtained at the office of Mr. A. M. Fowler, 1, St. Peter's square, Manchester. Tenders to be delivered at the office of Mr. Walter Hyde, town clerk, 2, Lord-street, Stockport. by January 16, endorsed "Tender for Economiser." The standard rate of wages in the distriot will have to be paid by the contractor in the construction of the work.

Birmingham.—The committee of the Birmingham Municipal Technical School invite tenders for the installation of the generating plant, fittings and appliances for both the electric lighting and transmission of power by electricity in the new school. Plans of the building may be seen, and specifications and forms of tender obtained, at the offices of Messrs. Hy. Lea and Thornbury, consulting engineers, 38, Bennett's-hill, Birmingham, on a deposit being made with them of £2 2s., which will be returned on receipt of a *bonâ fide* tender. The committee do not bind themselves to accept the lowest or any tender, and no tender will be considered except upon the prescribed form and accompanied by an undertaking that not less than the minimum standard rate of wages current in the district is paid by the contractor and sub-contractors (if any). All tenders must be sent in to Mr. Geo. Mellor, secretary, endorsed "Tender for Lighting," on or before January 12.

Hanley.—The Corporation of Hanley are prepared to receive tenders for the supply and erection of the following plant: Contract No. 10—extension of engine-house plant, including 200-kilowatt alternator, 25-kilowatt alternator, and 20-kilowatt exciter, each separately driven by a compound steam-engine, with all necessary steam and exhaust pipes, valves, switchboard, and appurtenances; Contract No. 11—extension of condensing plant, consisting of circulating pump, air-pump, boiler pump, surface condenser, with all necessary pipes and appurtenances. The drawings can be inspected, and specifications. prepared by Mr. G. H. Cottam, Corporation electrical engineer, together with general conditions and forms of tender, can be obtained at the offices of Mr. Joseph Lobley, Town Hall, Hanley, on payment of 5s. Tenders are to be delivered to Mr. Arthur Challinor, town clerk, on or before January 5, 1895. The Corporation do not bind themselves to accept the lowest or any tender.

RESULTS OF TENDERS.

Blackburn.—For the supply of electricity meters to the Town Council, the tender of Messrs. S. Z. de Ferranti has been accepted.

Sunderland.—The School Board have accepted the tender of Mr. Davison Taylor to supply and fit apparatus necessary for lighting the Board offices by electricity according to specification for the sum of £39. 15s.

Enniscorthy.—The tender of Messrs. Curtis and Sons, Middle Abbey-street, Dublin, has been accepted by the Governing Com-

Digitized by Google

mittee of the Enniscorthy District Lunatic Asylum for the supply and fitting up of telephonic apparatus throughout the asylum buildings.

Cardiff.—The Corporation have accepted the following tenders for the supply of steam coal for the electric lighting works at Canton for the six months ending June 10, 1895: W. T. Beavan, 120, The Exchange, Cardiff, 500 tons large coal £318. 15s; British Coal Company, 40, Miskin-street, Cardiff, nut and small coal as required to June 10, 1895, nut coal 9s. 9d. per ton, small coal 7s. 3d.

BUSINESS NOTES.

Portsmouth.—The baths have been lighted electrically.

Bristol.—The Clifton Down Hotel is to be lighted electrically.

Douglas (Isle of Man).—It is proposed to extend the electric tramway to Snaefell.

Longton.—The Queen's Theatre, which was burned, is being rebuilt. It will be lighted throughout electrically.

Brechin.—An agreement has been signed between the Police Commissioners and the Scottish House-to-House Electric Lighting Company.

Parndon.—Messrs. Crampton and Co., Cambridge and Yarmouth, have installed the electric light in large mills at Parndon, Hertfordshire. Water power is used.

Elmore's Patent Copper Depositing Company, Limited.—The accounts for the year ended June 30 show a loss of £10,435, thus increasing the debit balance to £31,953.

City of London Electric Lighting Company.—The allotment letters and letters of regret in respect of the further issue of £200,000 debenture stock issue have been posted.

Leith.—Messrs. Wm. Jeffery and Son's drapery warehouses have been lighted electrically. Both arc and incandescent lamps are employed, the total candle-power being 20,000.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 23rd inst. amounted to £938, as compared with £604 in the corresponding week of last year.

Chiswick.—The surveyor to the Local Board has reported that the work at the electric lighting station is now rapidly progressing, nearly the whole of the foundations having been laid.

Altrincham.—The Altrincham Electric Supply Co. propose to at once commence the supply of electric light in the Altrincham and Bowdon districts. The price which will be charged is 8d. per unit.

Bilston.—After some consideration the Township Commissioners have resolved to increase the lighting plant in the market at an estimated cost of £65 odd. It is proposed to provide four additional arc lights, two of which will be placed in the open market.

Engineers' Advertising Protection Association, Limited.—This Company has been registered with a capital of £5,000 to supply at all times—to engineers in particular—by correspondence or otherwise, confidential and reliable information touching advertising matters generally.

Anglo-Portuguese Telephone Company, Limited.—The coupons No. 14 of the Anglo-Portuguese Telphone Company, Limited, first mortgage, and No. 9 of the second mortgage debentures will be paid (less income tax) by Parr's Banking Company and the Alliance Bank, Limited, on and after the 1st prox.

Leeds.—The Corporate Property Committee of the Leeds Corporation, under the presidency of Alderman Sir Edwin Gaunt, have received a form of agreement between the Yorkshire House-to-House Company and the City Council for the supply of the electric light by that company to the Town Hall and Municipal Offices. The agreement has not been approved.

Rogers's Arc Lamp Company, Limited.—This Company has been registered with a capital of £20,000 in £5 shares, to acquire and turn to account certain inventions of J. W. Rogers for improvements in arc lamps, and to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity, electrical apparatus manufacturers, and the business of an electric light company.

Acton.—At the last meeting of the Local Board the Chairman said that it was very desirable that the residents in the district, and particularly those in the High street, should make the Board or their successors acquainted with their feeling with regard to the proposals of the London United Tramways Company to use electric traction, and to carry their line through the High-street as far as Acton Hill.

Maidstone.—The Urban District Council have held a meeting, at which Mr. Morling said, as the Council evidently intended doing nothing with the electric lighting order, he desired to give notice that at the next meeting he should propose that the order should be put out for tender. He maintained that the town should have the benefit of the money which had been spent in obtaining the order.

Smoke and Fumes Annihilator, Limited.—This Company has been registered with a capital of £120,000 to carry on business as manufacturers of smoke annihilators and other apparatus for the treatment of smoke or fumes, to manufacture and deal in carbon, ammoniacal or other liquor, and all other residual products obtained in the treatment of smoke or fumes, and to carry on business as general engineers, ironfounders, machinists, builders, painters, chemists, etc.

City and South London Railway.—The receipts of the Company for the week ended December 23 were £968, against £952 for the corresponding week of 1893, or an increase of £16. The total receipts for the current period of the present half-year amount to £22,447, as against £21,049 in the corresponding period of 1893, an increase of £1,398.

Sunderland.—A meeting of the Town Council was held on Wednesday, when some discussion was provoked by a proposition to appoint an assistant electrical engineer at a salary of £120 per annum, and this was ultimately carried, despite an amendment by Councillor Summerbell that the subject be brought up again six months hence. It was agreed that the electric light be placed in parts of the free library, at a cost of £69 for fittings, lamps, etc.

H.M.S. "Magnificent."—This new vessel, which has been launched at Chatham, will have three dynamos, each of 400 amperes and 80 volts, from which, by means of insulated cables, the current will be distributed to the search and incandescent lights. About 700 electric lamps will be fitted for the lighting of the ship, and this will be carried out in a very efficient manner, even the coal bunkers having enough lamps to brilliantly illuminate them when coal is being trimmed or being worked down to the stokeholds.

British Electro-Chemical Agency.—A petition for confirming a resolution reducing the capital of this Company from £75,000, divided in 7,500 shares of £10 each, to £50,000 divided into 2,500 vendors' shares of £10 each, and 5,000 ordinary shares of £5 each, such reduction to be effected by reducing the nominal amount of each of the 5,000 ordinary shares from £10 to £5, was on November 1 presented to her Majesty's High Court of Justice, and is now pending. The list of creditors of the Company is to be made out as for February 1, 1895.

Smoking Concert.—Mr. T. Harding Churton entertained his staff of employés at a smoking concert held at the Grand Restaurant, Leeds, on Friday last. During the course of a very enjoyable evening, Mr. Churton thanked his staff for the loyal manner in which by good honest work they had enabled him to so largely increase the scope of his operations during the past few years. Mr. W. S. Parkinson, in moving a vote of thanks to Mr. Churton for his hospitality, expressed a hope that they might have such gatherings annually. Mr. H. M. Tempest seconded the motion, which was carried with acclamation.

Leicester.—The Corporation scheme for supplying the electric light in the centre of the borough was completed at Leicester on Thursday last week, when the new illuminant was turned on in several shops with which the connection has been made. It is not at present intended to light the streets with electricity, but considerable improvement of the public lamps is contemplated, the new incandescent light being adopted near the clock tower. Some of the mains for the electric light are not yet laid, but the installation is sufficiently advanced to enable the Corporation to keep up the supply where the fittings are completed.

Leeds Tramways.—The Bill deposited at the Private Bill Office, which bears the endorsement of Mr. John Harrison, town clerk, for the construction of further tramways by the Leeds Corporation provides that the motive power may be either animal, steam, or other mechanical power, including electricity. The eight sections proposed to be constructed are described in the Bill. All the tramways will be double lines, and the period for their completion is five years from the passing of the Act. The Corporation ask for power to borrow for these works, and for relaying the existing tramways, the sum of £213,000.

Eastbourne.—The parish church is now illuminated by the electric light, the installation having been provided by the Eastbourne Electric Light Company. The church has 75 lights in all. The nave is lighted by five 5lb. wrought-iron coronæ of handsome design, and the chancel has 25 lights, chiefly distributed in wrought-iron brackets. The remainder are distributed in the side aisles and vestries. The switching arrangement is perfect, as ensuring economy in using the light, it enabling as few or many lights to be used as required. The whole installation has been carried out in accordance with the Phœnix Office fire rules.

Chelmsford.—A document, addressed to the Chelmsford Electric Lighting Company, has been signed by a large number of consumers of electricity in the town, expressing the feeling that it would be a decided advantage to have the current supplied as many hours a day as possible, especially during the dark days before and after Christmas. At present the current is on from two o'clock in the afternoon until ten o'clock the next forenoon. The consumers stated that they require a light all day on such days as are now being experienced, especially in dark shops and warehouses. Some are asking also how they could cook their dinner, if they had the electric cooking apparatus, when the current is off just at dinner time?

Harrow.—In consequence of the decision of the public meeting, to which we have previously referred, held to consider whether or not the Board should go forward with the electric light scheme, the Harrow Local Board have resolved to sell the right of the provisional order granted a few months ago to Messrs. Crompton and Hawtayne on the condition that these gentlemen pay the full cost the Board have been put to to secure the order. Messrs. Crompton and Hawtayne offered £300 for the provisional order, and agreed to sell the plant, etc., to the Local Board in seven years if the Board then desired to light the town themselves, subject, of course, to certain conditions. The expenses of the Board have been somewhere about £340, so that it is probable the new Council will accept the offer.

Worcester.—Alderman Walter Holland mentioned at a meeting of the Watch Committee of the Town Council last week the question of the lighting of Stanley-road, Vincent-road, and Cecil-road. An estimate prepared by the city engineer showed that the cost of lighting the streets by electricity would be £460 for 11 street lamps, and that the amount payable to the gas company for lighting the streets would be £24. 4s. per annum. As the mains would pass near the workhouse, Mr. Caink suggested that the new Board of Guardians might decide to light the workhouse with electricity. It was decided to defer the matter for the present.

Appointments Vacant.—A junior demonstrator and lecturer in physics is required by the committee of University College, Nottingham. The salary is £120 a year. Applications must be sent to the secretary by January 11.—The Blackburn Corporation want an electrical engineer to take charge of their station when completed. The salary is £200 a year.—The St. Pancras Vestry require an assistant engineer at the Regent's Park central station; salary £3 per week. Also a youth as improver; salary 10s. per week. Particulars appear in our advertisement columns.—The Corporation of Bristol are prepared to receive applications for the appointment of clerk of works to superintend the electrical installation at the Guildhall; salary £2 per week. Particulars are given in our advertisement columns.

Cardiff.—The series of experiments which has been carried on during the past few weeks in connection with the installation of electric light at Cardiff, has resulted so satisfactorily that the light was turned on permanently on Saturday evening. The members of the Lighting Committee of the Corporation, as well as the engineers, have been congratulated by many persons in a position to speak on the matter on the present result of the scheme, and the excellence of the light. The reason the light was not used permanently until Saturday was that the officials were waiting until reserve rectifiers and transformers were at Cardiff, ready to be used in case of a breakdown. The whole of the machinery is now in working order. After the holidays it has been decided by the Corporation to give the gas company the required week's notice to cease supplying gas to street lamps over the area covered by the electric light.

Glasgow.—Fourteen of the Corporation cars have been fitted with electric lamps, and the necessary fittings will be provided in all the vehicles as quickly as the contractors are able to overtake the work. The plan now adopted has the advantage of having been tested with satisfactory results. The lighting of each car is effected by means of four lamps—two inside and two outside. The electric current is provided by four batteries, two being placed at either end of the car. Each lamp is of 8 c.p. The inside lamps or domes are attached to the roof in such a manner as not only to light the interior of the car, but also to illuminate the platforms and steps. The outside domes are supported on hollow standards rising from each end of the vehicle, the electric wires being inside the standards. The outside domes contain the coloured signal lights indicating the route on which the cars are plying, and at the same time light the tops of the vehicles.

Bath.—The Town Council have considered an application from the electric lighting company for the consent of the authority to an application to the Board of Trade for a provisional order extending the license to 42 years, and also the area of lighting. Mr. E. B. Titley, solicitor to the company, was heard in support of the application. He said that about £45,000 had been spent by the company, and only a dividend of 4 per cent. had been paid. If the authority would not consent to the provisional order, the company were prepared to hand over the undertaking at the amount of their capital expenditure. After a brief discussion, it was agreed not to consent to the application, on the ground that it was desirable that, at the expiration of the seven years' license, the Council should take steps to get the electric lighting into their own hands. It was also agreed to obtain the services of a consulting electrical engineer to advise them generally upon the subject.

Hampstead.—An extension of electric lighting in Hampstead has recently taken place, the premises of several tradesmen in the High-street being lighted under the supervision of the Vestry's Electric Lighting Committee. The current was first switched on to the premises of Mr. E. Elliott—himself a member of that committee—which have been provided by Mr. W. Thompson, of Heath-street, with two Crompton-Pochin 1,000-c.p. arc lamps for external illumination, together with a number of 16-c.p. incandescent lights inside Mr. Elliott's two shops. Other shops were also illuminated by means of incandescent lamps. Amongst those who were present at this introduction of the electric light into the High-street were Mr. James Thwaites, chairman of the Electric Lighting Committee, with Messrs. Padbury, Bence, C. H. Reed, and Underwood, members of the committee, Mr. Chattock, the electrical engineer, and Mr. Roscoe, representing Messrs. Siemens Bros. and Co., the contractors for the laying of the mains, which have now been brought as far as Gayton-road. There is now every prospect of the electric light being generally adopted in the Town Ward.

Swansea.—Mr. E. R. Daniel, at a meeting of the Town Council, moved the adoption of the minutes of the Property and General Purposes Committee, which we gave last week. He remarked that the decision of the committee to proceed with the lighting of the town by electricity meant a large expenditure of capital, and if Swansea was to keep to the front the Council must do something finally in this matter. With regard to the establishment of a metallurgical school in the town, the committee considered there was no reason why the Government should not be approached for pecuniary assistance. The committee had considered the question put them by some other bodies as to the proposed new route from Swansea to Newport, and considered it was their duty to obtain as many lines as possible to the port. The purchase of the Swansea tramways was also a matter of great importance to the town, and it was now intended to appoint a committee to go into the subject. Mr. Mayne seconded. Mr. Viner Leeder asked what the estimate for carrying out the electric lighting and the erection of the refuse destructor to be used therewith had amounted to. The minute practically sanctioned the scheme, but mentioned no amount. The Town Clerk said Mr. Manville's report estimated the total capital expenditure on the electric lighting at £36,735, and on the destructor at £11,287. Mr. D. Davies proposed an amendment that the question of site and other matters should be further considered in committee before the scheme was proceeded with, but this received no seconder, and fell to the ground.

Brighton.—Last week, at a meeting of the Town Council, Councillor Stafford moved the adoption of the special report from the Lighting Committee recommending the public lighting of certain streets of the borough by electricity, to which we referred in our last issue. The committee thought the time had come when the ratepayers should receive some benefit, and that the streets should be better lighted. He believed it would be the commencement of a scheme that would be continued, and he believed the price of electricity would be so low as to be obtainable for every alley, square, and street in Brighton, and for every householder. The report was seconded, and Councillor Weston advocated the claims of North-road for the electric light, and suggested that that thoroughfare should be added to the list. Councillor Wishart hoped the "horrible light" would not be adopted for their narrow streets, and stated the light was totally unfit for business purposes. Councillor Halliwell thought the Council should wait if they were to go to the expense of providing standards for the electric light; and Councillor White hoped if the light was to be put on the Marine-parade, the Council would light the road instead of the heavens. Alderman Reeves thought the committee were a little hurrying the matter, and that the town would benefit by waiting. He moved that the question be discussed that day six months. Councillor Armes seconded. Councillor Turton thought the proposal a superfluous one, and Councillor Broadbridge considered the committee could easily wait another 12 months. The amendment deferring report was eventually defeated by 18 to 10, and the report was afterwards adopted.
